Susanne Cook-Greuter, a student of Jane Loevinger, continued the work of ego development by expanding upon the post conventional levels that Loevinger had researched. Her research supported differentiating Loevinger's Integrated stage into the Construct Aware and Unitive stages. This differentiation was corroborated by research done in leadership by Torbert (2004) and Joiner (Joiner & Joseph, 2007). Cook-Greuter also introduced the use of a sequence of "person-perspectives" to describe the developmental sequence.

The STAGES model

Terry O'Fallon modified Cook-Greuter's model and scoring system, in part by incorporating elements of the AQAL Integral Theory developed by philosopher and transpersonal psychology theorist, Ken Wilber. O'Fallon recognized that the ego development stages explored by Loevinger and Cook-Greuter could be explained by an underlying stage-by-stage unfolding of a small set of foundational factors that underlie the deep structure of human physiology and psychology intrinsic to human growth.

The Loevinger's WUSCT and Cook-Greuter's SCT are both theories empirically driven by data, with a minimal theoretical influence of top-down models or bottom-up cognitive processes; and their scoring method is largely based on matching to specific examples (or exemplar categories). The STAGES model, whilst built on the empirical data-driven discoveries of the Loevinger/Cook-Greuter lineage, departs from its forbearers in that it is theory-driven, describing an invariant 12 stage, 3-tier model of development, driven by a theoretically understood deep structure.

The STAGES model is composed of three dual cognitive orientations: Individual/Collective, Passive/Active, and Exterior/Interior, inspired by Wilber's AQAL model (O'Fallon, 2010a-b, 2012, 2013, 2020). These three dimensions move through three tiers of concrete, subtle and metaware experience (the fourth parameter) in a nested order of unfoldment. The theory suggests that human psychology unfolds through a 4-part process through each tier: passive-individual (Receptive), active-individual (Active), passive-collective (Reciprocal), active-collective (Interpenetrative). These might be referred to as the “four complexity” levels within each tier (Murray, 2017, p. 17). Figure A1 in Appendix 1 shows how each of these dimensions (or drivers) further refines the resolution of the model. The dimensions are:

- **Tiers**: O’Fallon conceptualizes three tiers of development, each apprehending an increasingly subtle category of objects, with each tier containing four stages of maturation (some versions of the model include a 4th Unitary tier). The first level, concrete, refers to a concrete level of cognitive development where the mind and senses apprehend concrete individual objects both within the exterior world and later the interior. This level of development is the realm of Piaget’s concrete operational thinking. The second tier, subtle, refers to a tier of formal operational development that apprehends subtle objects. At the next tier, the metaware tier, individuals have developed the capacity to differentiate awareness from the contents of awareness and are able to be aware of awareness itself.

- **Individuals/collectives**: Within each tier individuals are, generally speaking, aware of individual things and entities prior to collectives, groups, and systems, since the latter depend upon the former for their meaning. For instance, to have an awareness of complex family dynamics one must first understand individual psychology. Using only the 3 tiers and the Individual/Collective dimensions, one can define the 6 "person perspectives" of the model (see Figure A1).

- **Passive (Inside, 1st person)/Active (Outside, 3rd person)**. Each Person-perspective can be further differentiated into a passive and active half, yielding the 12 stages of the model. When one first learns something one begins by just being aware of it. One is receptive to its expression as one learns about it, it happens *to you*. With learning and practice there is the active repeated attempt to recreate the experience. Through repetition the state becomes more easily accessible. In a sense you have it rather it having you.

- **Exterior/Interior**: STAGES uses a fourth driver to specify sub-levels (half levels) within each of the 12 stages, which build up using first an exterior orientation then an interior orientation. Cognitively, exterior activity is understood prior to interior because one first applies a specific kind of cognition to the external environment before applying to oneself. Mark Forman (p.80, 2010) explains: “All the stages of identity development, therefore rely on different forms of outer-directed cognition eventually being used in the inner world of the self” Thus, an adolescent first applies formal operations to analyze and solve external challenges before applying formal operational thinking to the self. In doing so this transforms the organization of the self.

The STAGES model also includes an articulation of phenomenological "states," and the relationship between states and stages, that coordinates quite well with contemplative essence psychology, as described later (see O'Fallon's article in this issue).

Though STAGES is a relatively new model with limited empirical validation, the validation studies to date have shown very strong results. O'Fallon et al. (2020) describe a "replication study" that shows the STAGES scoring method replicates the prior Cook-Greuter/Loevinger SCT scoring method up to stage 4.5/Strategist. That paper also summarizes longitudinal data analysis including the upper levels, which shows evidence for the monotonic developmental sequencing of O'Fallon's newly defined highest stages (Metaware Tier). Murray & O'Fallon (2020, in this issue) used Item Response Theory and Rasch analysis to evaluate additional validity metrics, including: within-test item normality, item standard deviations, Cronbachs-Mesbah analysis of test lengths, factor/component analysis, item correlations, test strata/discrimination analysis, and overall test strength.

In this section an overview has been presented of the territory of adult development and particularly the lineage of constructive developmentalism initiated by Jane Loevinger, continued by Susanne Cook-Greuter, and more recently articulated by Terri O’Fallon. Through investigating adult development these researchers have uncovered stages of mature adult development, and the underlying developmental processes, that we can relate to the stages of contemplative development as articulated by the Indo-Tibetan essence tradition. While there are clearly some differences, what is of particular interest is that the Western research indicates these stages of cognitive and meta-cognitive unfoldment are perhaps not just constructed by the meditative process but are indicative of a more universal transcultural and human process. The developmental process is catalyzed by meditative development but there are other factors that support this growth such as cognitive complexity, relational intelligence, and differentiation from childhood psychological structures.

Below we summarize aspects of the model and reiterate, in a bit more detail than we did in the Introduction, why it is a very good fit for coordinating contemplative essence psychology and adult developmental theory.

- In STAGES the entire developmental sequence is based on *non-conceptual modes of perception and awareness* as they generate ever new distinctions (categories) in the mind. The exploration and development of *what one is aware of* is central to contemplative methods. Though most adult developmental models focus on the linguistic or conceptual aspects of meaning-making, STAGES grounds cognitive and metacognitive thought in their non-conceptual and concrete precursors, as is common in contemplative models. It maps patterns in the growth of mastery, and of transforming implicit knowing (subject) into explicit knowing (object) and meta-knowing (metacognition) – that repeat for each new category of distinctions. This too provides an excellent framework for representing aspects of contemplative essence psychology.

- The STAGES model is based on a progression of "*Tiers*" called Concrete, Subtle, and Metaware, and Unified, each representing increasingly subtle forms of objects of awareness. It coordinates closely with predominant neo-Piagetian models of cognitive development, as its progression from Concrete to Subtle matches the cognitive progression for concrete to formal operations (abstract and logical thinking). Contemplative essence psychology likewise maps a progression of awareness (metacognitive capacity) of increasingly subtle mind/body phenomena – that can be mapped directly to the four tiers in the STAGES model.

- STAGES specifies a repeating nested pattern of unfolding within each tier, which involves moving from *exterior to interior* objects, from *individual to collective* objects, and from *passive to active* orientations to perceiving each type of object. These patterns in the unfolding of awareness map directly to principles in contemplative essence psychology (as we explain later).

- STAGES' treatment of the exterior/interior dimension maps to the "*event perspective vs. mind perspective*" used in the essence tradition.

- STAGES contains a sophisticated model of the relationship between *stages* of cognitive complexity, *states* of consciousness, and stable -stage orders of perceptions (views); that latter of which maps well to modes of operation (existential views, or basis of identity) described in contemplative essence psychology.

- STAGES describes the progression within each tier as: *receptive, active, reciprocal, and interpenetrative*. It follows contemporary cognitive science in noting that the perception of any object begins with unanticipated fleeting glimpses (receptive *states*), which with practice become stable skills for observing an object at will (active), and eventually become the automatic (unconscious, effortless, and "natural") perception of the object (interpenatrative). Essence traditions prioritize the attainment of levels of effortless "*view*," a sequence in the development of the "basis of operation" of awareness – which is well described by the interpenetrative phase in STAGES.

- STAGES fleshes out *territory in the higher tiers* to a greater degree than other models, and in a way directly analogous to contemplative essence psychology. It explicitly mentions awareness of awareness, the apperception of timeless awareness, spacious freedom, emptiness (of different forms), and fullness, which maps to concepts used in contemplative practice.

- STAGES includes a *shadow-work* model articulated according to developmental level, which coordinates well with the deconstructive and emptiness elements of the essence traditions. I.E. it explicitly includes and coordinates the contrasting elements of *complexity/skillfulness/adaptation* and *freedom/deconstruction/liberation* inherent in the essence traditions.

Next we will explore Buddhist contemplative essence psychology. We will make a few references there to adult development, but for the most part will save our integration of the eastern and western models until the section on "Integrating Contemplative Essence Psychology and adult Development."

2.3 Buddhist Essence Psychology: mahamudra and rdzogchen

In the introduction we mentioned how the Indo-Tibetan schools represented the third turning (paradigm shift) in Buddhism (associated with the term Vajrayana), specifically the mahamudra and rdzogchen schools, constitute a system of "contemplative essence psychology." And we touched on how they differ from earlier phases of Buddhism (the Hinayana and Mahayana traditions). The shape of these three turnings of Buddhism is further articulated in Appendix 3.

Contemplative essence psychology includes the Hinayana-based theories of mindfulness and contemplative psychology that are currently popular but adds theory and practices for the experiential understandings of the constructed nature of sensation, body, thought, self, time/space, dualistic perception, and the individuality of the attentional system which reveals a progression of metacognitive identity, or basis of operation, beyond self, time, and individuality.

Below we describe Buddhist Essence Psychology, which is discussed in more detail in Appendix 4, and in even more depth in Churchill (2018).

Mahamudra

Essence mahamudra refers to the approach of direct investigation into the nature of mind and it is comparable to the rdzogchen teachings of the rNing ma and Bon traditions (Ringu, 2007). The Tibetan Bon tradition locates its genesis in the shamanic traditions originating 9,000 years ago, while the Indian Buddhist tradition locates its initiation 2,500 years ago. As such, the tradition is a wealth of knowledge, and practice, that is still alive in the form of the five Tibetan lineages of the Bon, Nyingma, Kagyu, Sakya, and Gelug schools.

In order to understand mahamudra it is necessary to understand the concept of *tawa (Tbt.)* or *dristi (Skt.)* which literally means, *view,* meaning the view from which one experiences phenomena. Brown (2017) explains that the view is dependent upon the basis of mental operation (spod yu), the loci of identity, level of awareness or vantage point from where the mind's metacognition is operating. In essence practice the meditations are less about meditating on something as they are about learning to operate from a new level of awareness, a new basis of operation, and from there to take a new perspective or view on experience.

According to Ras chung, student of Mi la ras pa, there are four main bases of operation: awareness fused with thought and self-structure, awareness beyond self-structure, awareness beyond temporal processing, and awareness beyond the information processing system. Each level is sequentially freer from the subtler and subtler reifications of unconscious psychological and perceptual structures.

Indo-Tibetan psychology is based on an understanding of four levels of mind, four main basis of operation; the coarse, subtle, very subtle and awakened. These are four levels of mental experience are always present in experience, but they are not necessary conscious. Whether a level of mind is made conscious or not is dependent on the level of view, the basis of operation from which identity is operating. The basis of operation shifts during meditation and initially this will be a brief *state* but as practice continues the state will become a *trait,* and a permanent developmental stage of identity.

Each basis of operation has the capacity to view phenomena (take the *event perspective*) and the capacity of self-recognition (the *mind perspective*). The event perspective refers to the perspective of mental objects perceived at that particular level of awareness i.e. concrete objects such as the thoughts and subtle objects such as abstract patterns. The mind perspective refers to the perspectival capacity to self-reflect and recognize the level of awareness from which the mind is operating i.e. to make awareness (the subject) the object of itself.

In Appendix 4 we describe the four-yoga model of sGam po pa's mahamudra. In it the meditator first calms the mind (shamatha), then by gaining insight (vipashyana) into the constructed nature of the self, time, and individuality recognizes awareness to be already beyond all structures to a basis of operation, buddha nature, without any reference points (Brown, 2006). The four methods described are: One-pointed yoga (calm/staying; shamatha), Non-discriminatory yoga (insight; vipashyana), One taste yoga (union of calm staying & insight), and Non-meditation yoga (mahamudra).

rDzogchen

rDzogchen, or "great completion practice," is the coordination and culmination of contemplative practice in the indigenous Bon tradition and the oldest Buddhist tradition in Tibet, the rNing ma. In the Bon tradition the lower stages focus on shamanic practice while the rNing ma model addresses the foundational Buddhist practices of the Hinayana. Both traditions then progress through Bodhisattva teachings on emptiness and compassion, and then Tantric approaches using visualization and yogic techniques to culminate in rdzogchen.

As the most pertinent example of the rdzogchen tradition we focus on the A Khrid system from Bon rdzogchen. It provides a systemized approach that parallels and expands upon the mahamudra four-yoga model mentioned above. In their translation of the A Khrid pith instructions, Brown & Gurung (2017) reveal how the commentary of the A Khrid divides practice into three main phases: bringing the unripened mind stream to ripening, bringing the ripened mind stream to liberation, and bringing the liberated mind-stream to the completion of Buddhahood.

The first of these prepares the mind for emptiness practices through methods including contemplating impermanence, setting clear intentions, and mentor-bonding. The second phase, of tasting and developing realization, contains the core elements of the contemplative essence psychology discussed in this paper. It includes ten practices leading to the capacity to operate naturally from awakened awareness, the level of lucid, open non-dual awareness, prior to the constructions of the information processing systems of perception, attention, temporal awareness, self-construct, emotion and cognition. The third phase describes esoteric practices that, given the base capacities of the liberated mind, expand that capacity into all aspects of the conscious and unconscious self, and into all daily actions and decisions; ultimately purifying the mind of all negative qualities and perfecting all positive capacities available to the human condition.

Awakening etc.

Though contemplative and religious traditions have a wide variety of meanings for terms like awakening, enlightenment, and realization, within the Indo-Tibetan schools there is fair agreement upon and precision in describing, if not the conceptual map and category boundaries, at least the forms of experience and capacities developed by various contemplative practices. The practice maps and experience maps can be quite detailed up through many stages of contemplative realization, and, though there will eternally be disagreements on the nuances within academic scholarship, the constructs described within the contemplative essence traditions have quite specific meanings.

Prajna: insight into impermanence, reactivity, no-self, and emptiness. In the essence tradition of mahamudra and rdzogchen, concerned as they are with the nature of awareness itself, metacognition is understood through the important concept of prajna (skt: prajna). This term technically refers to the experiential cognitive recognition of impermanence (anicca), reactivity (dukkha), no self (anatta), and in the Mahayana, emptiness (skt: śūnyatā). The term is sometimes translated as wisdom, discriminating knowledge, or insight (Buswell, 2013). Jna translates as consciousness, knowledge or understanding, and the term Pra is an intensifier that translates as higher, greater, or supreme. Training in ethics, concentration practice, and Prajna comprises the fundamental three trainings (sikkha) common to all Buddhist traditions. In terms of this work on Indo-Tibetan essence practice, prajna (Tbt:s hes rad) is synonymous with contemplative metacognitive insight. This metacognitive insight, particularly into the constructed nature of experience (śūnyatā) is what leads to the recognition of primordial awakened awareness known as jnana (Aky: jnana) (Tbt: ye shes). The distinction between prajna and jnana, metacognitive insight and primordial awakened awareness is fundamental to understanding the mechanism of essence practice. Ringu Tulku (2017), a mahamudra teacher in the Kagyu Tradition describes:

> The word yeshe yé is short for yé né, which means ‘right from the beginning’ or ‘primordially’. Some people translate it as ‘pristine’ or 'pure', meaning that it is untouched and unstained, and has been there all the time. It is the way it always was. So yeshe is discovered with sherab. Yeshe is understood by sherab, or approached by sherab. Ringu (2017).

In other words, primordial awakened awareness is discovered and understood by metacognitive insight. He continues:

> The difference between sherab and yeshe is very subtle and slight. But I think we can say that yeshe is the most natural state of our awareness or consciousness, which is unstained, uncontrived and completely ordinary. It is there all the time, but we don’t recognize it. It is sherab that brings about the recognition, but of course they are not two separate things. Ringu (2017).

Primordial awareness is always there, but one typically doesn’t recognize it. It is metacognitive insight that brings about its recognition, but these are not actually in essence separate, as metacognitive insight is an expression of primordial awareness.

Awakening. As discussed in the previous sections, the Indo-Tibetan essence traditions have been practiced as a form of psychological development in some form for thousands of years. The goal of the contemplative essence psychology of mahamudra and rdzogchen is the development of full human potential known as a Buddha in Sanskrit or Sangs rgyas in Tibetan (Buswell 2013). In Sanskrit, Bud means awakened and Buddha literally means *awakened one*. The Tibetan term gives more insight into the goal, Sangs means *purifying*, the purifying of emotional and cognitive distortions, and Gye rgyas means *flourishing, the flourishing of the 80 positive qualities of an enlightened mind*.

Awakening usually refers to contemplative achievements that are actually part-way on the path to Buddhahood, and one can experience aspects of awakening without its stable attainment, and while still early on the path of full purification of the mind. The process of purifying emotional and cognitive distortions is a goal that Western psychology also aspires to. However, the depth of awakening in the Indo-Tibetan tradition goes beyond the awakening from psychodynamic issues, and from dysfunctional cognitive and behavioral patterns that functioning in contemporary culture necessitates. This fruition of human potential manifests itself through:

- the different phenomenological dimensions that are fully cognizant through waking, dreaming, and deep sleep states known as the three-fold embodiment of unbound spaciousness (dharmakaya), lucid awareness (samabhogakaya) with non-dual geometric archetypal light fields (buddha realms), and the physical emanation body of everyday reality (nirmanakaya);

- the primordial wisdoms of mirror-like clarity, equanimity, discriminatory awareness, all-accomplishing executive functioning, and all-pervading spaciousness; and

- enlightened activity in the form of skillful application to reduce individual, cultural and social suffering and lead beings towards the realization of their full potential (Thrangu, K. 2011).

Omniscience. Omniscience (Skt. sarvajñāna; Wyl.ie rnam mkhyen), a term with metaphysical implications quite uncomfortable to our modern worldview, yet which is used somewhat uncritically in some contemporary spiritual communities to describe high stages of awakening, actually had a specific technical and, arguably non-metaphysical, definition in Indo-Tibetan Buddhism. For instance, the Bodhisattva Maitreya's work the Abhisamayalankara, which is studied by all the lineages of Tibetan Buddhism, outlines eight topics of study, the first of which is omniscience. Omniscience refers to the culmination of the knowledge, skill, and direct experience of how to reduce suffering and increase happiness through each of the Buddhist vehicles of practice. The goal of the bodhisattva includes liberating all sentient beings from their suffering and pain, and developing these ten aspects of knowledge within them (Ponlop, 2003).

Along with meditative (and metacognitive) training, Indo-Tibetan Buddhist contemplative education also emphasizes *cognitive* training comprising knowledge in ten fields that have been the focus of the traditional course of study since the first monastic universities of Nalanda in India and Samye, and rDzogchen monasteries in Tibet. These ten fields can be reduced to five:

logic, language, medicine and healing, the arts, and the Buddhist science of mind. Maitreya, in The Ornament of the Mahayana Sutras (one of the five treatises of Maitreya) states:

> If efforts are not made in the five sciences, even great beings will not attain omniscience. Therefore, to refute and to nourish, and to attain omniscience, make effort in the five sciences. Gyatso, (2016, p.42).

Recall that before modernity, perhaps in the Middle Ages and before, it was possible for an intelligent and dedicated individual to learn the basic elements of almost every field of knowledge. Today it is impossible to be a polymath ("Renaissance" man or women) in the same sense of having at least a theoretical grasp of most of the knowledge disciplines known to one's local culture. Like the child in awe of her parent, it may have seemed to those living "on the streets" in ancient times that such learned individuals actually "knew everything." In bygone times such a rare person was also poised to espouse meta-knowledge about the state of knowledge as a whole, including "how everything is connected" and the relevance or import of any aspect of knowledge.[4] This is what was meant by "omniscience."[5] It was not just about experiencing the depths (or radical emptiness) of consciousness, but also about accruing the practical knowledge allowing one to *apply* one's wisdom to many (or all) aspects of life, including in ethical and political domains.

There exists bias in the West towards seeing contemplative development as entirely a non-conceptual or metacognitive process. However, in actuality the psychological development of essence practice takes place within the context of a larger liberal arts education.

Buddhahood. Buddhahood is often described as the fullest expression of wisdom and compassion. Wisdom is defined in Buddhist contemplative psychology as the capacity for deconstruction and liberation from fusion with all cognitive structures so that the light of awareness never goes out whether in waking, dreaming, or deep sleep states. Compassion refers to the development of skillful responses to the needs of other beings. Compassion therefore does not just refer to an affective state, but to the construction of cognitive capacities and skills to understand and respond to practical reality in such a way as to reduce suffering and lead other beings in the direction of their full potential. This is the same process discussed in the research on ego development; the increasing capacity for defusion allows for deconstructive shifts in the fundamental basis of operation (wisdom), from which more complex adaptions to life circumstances can be made (compassion).

In the broader tradition of the Mahayana, within which the essence tradition is the quintessence, Buddhahood refers not just to a deconstructive liberation from all experience, but also a deeper integration and reorganization of cognitive structures brought about through a profound understanding of the various stages of practice and their pedagogical application in reducing human suffering.

---

[4] Of course, academics today do this by the thousands, but, each has only a very limited grasp of the full knowledge produced in their time.

[5] In addition, from a more esoteric perspective, rigorous research into psychic phenomena indicates that it may be possible to obtain "non-local" knowledge (i.e. not constrained by space and time in the normal ways). Thus, though modern sensibilities prohibit us from considering anyone as literally "knowing everything," we can still consider the possibility that an adept could open perception or consciousness in such a way that they become a conduit for knowledge (as needed by others) that they did not previously "know" in the usual sense.

Therefore, a Buddha is an awakened being, having fully purified the emotional and cognitive distortions of multigenerational traumatic conditioning, and opened to the omniscient capacity to lead other beings to that realization.

Though, from our contemporary context, Buddhahood can be interpreted as a horizon, a hypothetical state pointed to by a path, the various aspects of awakening and the outlined steps toward Buddhahood can be confirmed experientially and incrementally through dedicated practice.

3. Integrating Contemplative Essence Psychology and Adult Development

This section focuses on the mapping of the contemplative essence psychology of mahamudra and rdzogchen in terms of mature adult development and is informed by the literature on metacognition. We have three goals. First, to show that contemplative essence psychology contains many of the conceptual tools and pragmatic understandings of a well articulated psychology of adult development. Second, we will explore how contemplative essence psychology can inform modern developmental models, and can deepen the goals of modern psychology to support mental health, and psychological growth and transformation. Third, we will discuss how modern developmental models can inform contemplative essence psychology to make its principles more available to the modern mind.

In the modern western understanding of the structural stages of development, such as those developed by Freud, Piaget, Fisher, Commons, Loevinger, Cooke-Greuter, O'Fallon etc., has developed over the last 100 years due to the sophisticated maps developed from third person scientific research into the longitudinal growth of human beings through the life span. Yet the maps and practices of the mahamudra and rdzogchen contemplative traditions offer Western psychology a perspective and path of human potential evolution and flourishing previously unexplored in Western psychology, and that is deeply needed in the contemporary world.

This section begins by exploring the *history* of the east/west convergence, including *methodological* differences, and *contemporary* clinical and research advances. We then propose principles of human psychological growth that integrate the developmental and contemplative fields, starting with *underlying mechanisms* that pertain along the full arc of maturation, and then focusing in on the *specifics of each stage* or level in the journey.

The section also offers a glimpse into an integrative process that could engage many generations of future dharma practitioners and psychologists in the process of reducing human suffering and actualizing potential.

3.1 Contemplative vs. developmental psychology: Historical and methodological comparisons

East vs. West: Phenomenology vs. Structuralism and Theory vs. Application

While much of our discussion will focus on the overlap between eastern and western approaches, the distinction between phenomenological and structuralist approaches to knowledge helps to contrast the two and explain their complementarity. The modern west seems to have learned so much about the human mind – its pathologies and modes of suffering, its capacities and further reaches, and the relationship between the emotional and cognitive modes of decision making – and yet it has kept this wealth of knowledge at an "objective" distance from embodied application in the lived lives of citizens. We seem to be as, or more, unhappy and neurotic vs. any historical period or civilization. In contrast, the findings of eastern contemplative traditions are not "up to snuff" in terms of modern scientific proof, and yet have always been aimed directly at improving the lives of real practitioners and cultures.

Wilber (2006) clarified the difference perspectives of these two methods of mapping psychological experience, through a distinction between *first-person* phenomenology, associated with the contemplative tradition, and *third-person* structuralism, found in Western forms of inquiry. Indo-Tibetan contemplative psychology is an ancient first person subjective, phenomenological tradition developed through deep introspection and interior research over many generations. The only way at this time to fully verify the claims of the tradition is to engage in the meditative journey oneself, to carry out the phenomenological metacognitive exercises prescribed and to compare the results to those collated and systematized by the tradition.

Compared to contemplative psychology, the field of adult development research is in its infancy. The work on cognitive structural development by Piaget, Commons, Fisher and others, and the work on constructive ego development by Loevinger, Cooke-Greuter, and O'Fallon are third-person structural disciplines. These maps have developed from the objective scientific structural analysis of studying levels of cognition and ego complexity in relatively large population samples. This research has led to the development of pedagogical approaches to supporting psychological development and education, but the development of these methods has come from the outside in, not the inside out. Perhaps because of this, or simply because of its relative recentness, it yet stumbles to create authentic applications as large-scale as its data sampling.

While science (adult developmental research, but also brain research, socio-political studies, etc.) can clearly add to the contemplative essence psychology by validating and extending its principles, it is less acknowledged that the eastern schools offer a wealth of information about the *experience* of adult development, especially at higher levels, as well as a treasure trove of nuanced practical instructions about pitfalls, dead-ends, common traps, fast-tracks, and diagnostic principles for practice guidance, that could help the findings of adult development become more widely implemented and more deeply understood.

Within contemplative methods, the mahamudra and rdzogchen stages of practice lead to the maturation of the very subtle and awakened bases of operations through deepening degrees of realization barely considered in western psychology. They are also accompanied by greater phenomenological nuance with respect to this development than does the Western research into adult development since the former in fact articulates the precise and actual means to bring about the transformation. The lineage libraries of the Tibetan monasteries consist of many meditation root texts, practice manuals, and commentaries developed over at least 2,000 years. Each of the five Tibetan schools has specific perspectives on the theory and practice of contemplative development, and continues to train contemplatives in these inner sciences to this day. This cultural wealth amounts to massive amounts of interior phenomenological research that has yet to be translated and/or generally disseminated.

East vs. West: Methodological Considerations

In integrating the Eastern and Western "sciences" of the mind, we should be explicit about their methodological differences. For example, though both make use of rigorous intellectual/logical analysis within peer communities employing debate; Tibetan psychology does not have an extensive research on the early stages of development (with regard to cognition); while western psychology does not have extensive research on the late stages of development (with regard to meta-cognition). Above we also mentioned the "WEIRD" biases of Western psychology due to the lack of diversity of subjects in most studies.

In comparison to pre-modern methods of psychological inquiry, the Western "scientific" study of psychology has several characteristics that underpin its strengths, yet also underpin its limitations: (1) its focus has been (with important recent exceptions) upon *pathologies* (the "disease model") rather than normative or exemplary human functioning; (2) as mentioned, it has taken a keen interest in the study of *children* (which is absent in pre-contemporary psychological, philosophical, and religious inquiry); (3) the *scientific method* itself, which is suspicious of the biases inherent in subjective insight, experiential knowing, and intuition; and bases rigor upon measurement and replicability; (4) its universalist, *non-metaphysical* and atheist bent, which forbids justification based on explicit dogmas (though it is still usually blind to tacit cultural biases); and (5) it can use random sampling and longitudinal measurements to discover generic developmental and cultural patterns not discoverable by less rigorous methods.

Eastern knowledge creation methods have their own comparative strengths: (1) they take seriously the revelatory powers of contemplation and intuition, giving *phenomenological inquiry* a high status, particularly in the human sciences of psychology, ethics, wisdom, and politics; (2) they afford more authority to the judgment of (communally validated) *adepts* in the fields of consciousness and wisdom; (3) they are explicitly aimed at *pro-social and emancipatory* aims (thus their close affiliation with religious traditions), and thus at the *practical* needs of people to find meaning, reduce suffering, and maintain positive psychological states – in contrast to Western science which is often either at an "objective" (and thus disembodied) distance from such matters, or is heavily influenced by market and political incentive structures; and (4) the belief systems and injunctions they produce have been *tested in grounded contexts and adapted for centuries*, which, though it does not guarantee the same degree of "truth" rigor afforded by the scientific method, but guarantees a much deeper relevance, practicality, and resilience than the vast majority of scientific investigations can afford (unless they have been "put to the test" for a very long time in multiple life contexts).

Subjective insight into the nature of one's own mind and cognition can be very difficult to articulate verbally/conceptually. In fact the rich detail and nuance of any deep experience is similarly ineffable, and language can only serve as a tentative pointer for others who have had the experience being described, or who are searching for that experience. The performance of a skill, such as leading a large group or maintaining equanimity in the face of frustrating circumstances, can have little correlation with one's ability to describe or theorize about the skill – the classic distinction between procedural vs. declarative knowledge (e.g. Anderson, 1983). Western science prioritizes declarative knowledge that can be used to describe, explain, or technologically invent something; while Eastern frameworks prioritize procedural knowledge that can be experienced and used in human decision making and action.

Traditionally, the esoteric wisdom of adepts becomes encoded into philosophical texts, poetic metaphors, allegorical stories, and practice injunctions carried forward by a culture. Those raised within such cultures can be *doing* and *experiencing* things that encode deep wisdom about the human condition, even though the individuals involved have no reflective understanding or what, why, or how they are doing (though some in those cultures may have high reflective or scholarly knowledge in that domain). The western observer, focusing on the lack of sophistication of the commonplace practitioner, can easily dismiss such knowledge as frivolous. This misses the important facts that (1) knowledge/wisdom can be rigorously *lived* without be explicitly "known," and (2) knowledge/wisdom can be carried tacitly at the level of *culture* in a way that is relatively independent of the explicit knowledge of participants.

Cultural rituals, worldviews, texts, and artifacts can harbor deep forms of knowledge, honed over centuries or millennia of use and tuning, that can remain hidden within individuals and invisible even to whole populations – as unreflectively embodied wisdom that later cultures or individuals can mine to recover (or regenerate) as explicit principles. As the sources and iterative tuning steps of this knowledge is usually lost, the "proof" of their validity is in lived experience, and not in scientific demonstrations or arguments. Yet the long history of adaptive use and cultural replication within Eastern traditions offers forms of validity that complement, not just contrast, the experimental methods of the West. Though it is not the modern way to simply *believe or adopt* them based on the legitimacy of authority figures, we can yet *respect and engage* them as presumably encapsulating valuable encoded knowledge about the human condition and its flourishing, beyond our Western world view and current science, that can be decoded and used.

East and West: Early Convergences

Before the recent advent and popularity of mindfulness practices in the west, the deeper regions of theory and practice of Asian contemplative psychology was known by a relatively small group of psychologists and theorists who struggled to reconcile Eastern and Western conceptions of development (Alexander et. al. 1990; Washburn, 2000; Dale, 2013; Wilber, 2007/2017; Brown, 1986; Engler, 1984).

Early longitudinal research by Alexander (1982) into Transcendental Meditation (TM) indicated that TM meditation facilitated ego development, as measured by Loevinger’s (1976) test of ego development. The TM subjects, who were prison inmates, progressed over a 4-year period from Loevinger’s *conformist* stage to the Expert *(self-aware) stage.* In a second one-year longitudinal study those inmates who were already meditating developed to Achiever (*conscientious) stage*, which corresponded to a dominance of mature abstract formal operations. However, Alexander's research into meditation, which included prolific efforts, with some 30 publications, only examined TM meditation, and unfortunately, due to the fringe perception of TM in academia, his results were not taken seriously outside the TM community, and no further researchers explored the relationship.

Mahamudra and Brain Research

As seen in recent research (Schoenberg et al., 2018) an increasing number of Western practitioners are developing through the traditional stages of contemplative realization. As such, the next step in the research is to investigate those few individuals who are stabilizing awakened awareness and purifying the unconscious mind through the practice of automatic dharmakaya release (rang shar rangrol).

Most of the brain-imaging research related to contemplative practice has been done within the mindfulness paradigm. However, Brown and associates recently completed an important study including the more advanced states covered in mahamudra. Drs. Brown, Brewer, Schoenberg, and Churchill recently completed a study with 30 intermediate level meditators that elucidated these stages of mahamudra meditation as having clear and distinct neurological signatures common to meditators at each stage of meditation (Schoenberg, et. al., 2018).

The study gave the first neurophysiological correlates of discrete mental states during Indo-Tibetan essence-of-mind practice using electroencephalography (EEG). The contribution of this study was its focus on the process of awakening as discussed in this paper, and represents an advance over prior studies focusing on mindfulness practices. The two higher stages of mahamudra meditation, one-taste yoga and non-meditation yoga, were differentiated into four specific meditative stages with each yoga comprising two meditative states.

The EEG findings indicated two major patterns. The first was that the current density upon entering the meditation state weakened in comparison to baseline control conditions observed in all frequencies and regions of interest. It is hypothesized that this was because the foundation of essence of mind meditation practice is to shift out of the cognitive/brain effort-effortless axis into recognizing aspects of mental experience that are always already present.

The second main finding was that while the default mode network activity in the medial ventral pre-frontal cortex and posterior cingulate cortex did not significantly increase across meditative states there was a unification of enhanced beta and gamma band density magnitude increasing from meditation state1 (ocean and waves) through to meditation state 4 (stabilized non-meditation awakened awareness) that spanned the anterior cingulate cortex (ACC), precuneus, and parietal lobes. This separation of the default-mode network and the executive functioning system reveals an active executive functioning and yet non-self-referential pattern of activity i.e. the executive functioning of the brain was operational while the basis of operation shifted beyond the self-structure to timeless awareness and then awakened awareness.

The results also indicate that as progression of the effortlessness became stronger there was enhanced ACC (executive functioning/self-regulation), parietal and insular activation suggesting the activation of brain networks associate with saliency, conflict monitoring, emotional control and shifts in perspective-taking that are inferred as supporting the very subtle meditative states of spacious awareness, non-duality, emptiness of phenomena, lucidity and referenceless.

Numerous EEG studies have revealed that EEG bands in the higher frequencies (beta, gamma) have been associated with the experiences of selflessness, non-judgmental awareness, and compassionate loving kindness (Schoenberg et.al, 2018). Our research showed that the anterior cingulate cortex (ACC), the central brain structure involved in executive functioning (working memory, theory of mind tasks, encoding reward prediction and prediction error, emotional regulation, cognitive processing), homeostatic physical states (hunger, thirst, awareness of breath etc.), and the encoding of stimuli valence through sensory modalities was active in the gamma bandwidth. This suggests *enhanced activity of executive control* capacities as they increasingly engage in maintaining *the view* as the practitioners shifted to deeper level of natural effortless meditation.

Increases in Gamma frequencies were also recorded in the parietal pathways of which the ventral stream relates to perspective shifting, such as from a first-person subjective perspective to that of a third person observer. Simultaneous to the continued activation of the parietal pathways, the self-referencing activity associated with the posterior cingulate cortex (PCC), part of the default mode network, remained deactivated throughout the stages of meditation. This was interpreted as relating to the phenomenological shifting from identification with the self (PCC) and to that of a referenceless basis of operation (parietal).

Beta frequency in the insular cortex associated with the metacognitive awareness and the modulation of interoceptive and emotional stimuli were also recorded. The researchers hypothesized that this was a possible neural marker for the non-preference or *equanimity* towards internal stimuli, which is a central marker of stage four, awakened awareness.

Further research is warranted, but one might hypothesize from the results that just as these states give specific neurological signatures so will the trait acquisition of these states as a permanent basis of psychological operation show specific neurological signatures. As practitioners engage in repeated meditative state practice, and the integration of the state into their lives, their basis of operation begins to permanently shift, and this is paralleled by a transformation in the neurological activity of the brain that can be measured. It is hoped that such research will support the legitimization of Indo-Tibetan contemplative psychology as a powerful means of reducing suffering and supporting the flourishing of positive mental states and altruistic engagement.

Clinical Implications

The adult developmental psychology of the Buddhist essence traditions has relevance to our understanding of psychopathology. It can be surmised that a path of contemplative practice that facilitates developmental would certainly make it easier to clear past developmental fixations. Forman (2010) in his text on integral psychotherapy noted that there has been little research on stages of adult development and psychopathology except that done by Gil Noam. In Noam and Dill's study of 89 adults in an outpatient facility (1991) it was discovered that whilst psychiatric symptoms exist at every stage of self-development there "was a clear decrease in symptom severity in those individuals with higher levels of identity [ego] development” (Forman, 2010, p. 95). This finding was also later corroborated with adolescents (Noam & Houlihan, 1990). Forman quotes the authors conclusions: “Correlations between identity development and symptom severity scores were uniformly negative indicating decreasing distress from psychiatric symptoms with increasing ego maturity, across all symptoms dimensions” (Noam & Dill, 1991, p. 214).

Further research into advanced practitioners of Buddhist Essence meditation, and psychopathology would be an important contribution since Noam’s research only tested subjects up to 4.0/Pluralist and none who had shifted a basis of operation to the metaware tier of ego development**.** The implications of snags rgyas, the flourishing of positive mental states in an enlightened mind, are profound for our understanding of mental health. The contemplative tradition teaches a means of treating the mind toward eradicating all negativity, so the mind becomes stainlessly clean (Tbt: dri med) and open. Within that openness the tradition's "80 positive qualities of mind" can flourish.

A study undertaken by Daniel Brown Ph.D. and Jack Engler Ph.D. (1986) revealed this potential in the Rorschach of a Theravadin meditation master. Rorschach data were taken from tests with meditators across the stages of contemplative development. Whilst intermediate meditators still showed signs of psychopathology and even personality disorders, the one Rorschach of the master showed that his intrapsychic structure had undergone a radical reorganization with no evidence of any sexual or aggressive drive conflicts, or any instinctual drive for that matter, pointing to the fact that there are no permanently opposed endopsychic structures at the core of the personality structure. This understanding of the possibility of the positive mind is essential to our understanding of mental health and the direction that investigation should pursue.

Further research into the phenomenology of the higher tiers of adult contemplative development will also reveal the subtler forms of pathology associated with these realizations. Essentially the crux of pathologies related to the different basis of operations, existential modes, is linked in the language of Indo-Tibetan contemplative psychology to the under or over application of emptiness. “Problems at any of those sub-phases will generate pathologies (for example, failure to adequately dis-identify or transcend creates a fixation or addiction; failure to adequately integrate or include creates an avoidance or allergy” (Wilber, 2017, p. 413). It will be increasingly important that these possible pathologies are understood so that psychologists trained in contemplative practice will be able to differentially diagnose and treat such pathologies.

3.2 Underlying Mechanisms in Contemplative and Developmental Growth

This is the first of two sections in which we will compare and coordinate contemplative and developmental models. In this section we focus on themes that address development as a whole, regardless of level. In the next section we focus on phenomena that arise at different levels. In other words, in this section we discuss the fundamental principles or underlying causal mechanisms of development and contemplative achievement, operating throughout *all* levels and explaining the transitions between levels. This includes patterns that repeat or reiterate several times across the spectrum of growth. In the next section we describe both capacities and practices as they *differ* across the spectrum of levels. Remember that adult cognitive development and contemplative development are overlapping but *distinct* processes. The "levels" described by developmental vs. contemplative theories are related but different, as we will discuss.

State, Stage, and View

Wilber-Combs Matrix. Ken Wilber, an important innovator in the transpersonal psychology movement, was also an innovator in the field of adult development. He synthesized over 100 psychological theories of development, revealing general trends and principles (Wilber, 2000). Through this body of work he saw that the concepts of state and stage were not sufficiently differentiated in transpersonal psychology models and eastern spiritual frameworks. Wilber (2007) clarified the difference between states of consciousness and stages of development, and thereby helped a generation of spiritual seekers and contemplative practitioners to understand that achieving an esoteric or "spiritual" state experience, even stable access to such an experience, does not necessarily translate into stable psychological maturity. Wilber (and Alan Combs) proposed a matrix separating the stages of ego/self development from stages of state identity (i.e. stable access to fundamental states). Along a horizontal axis they plotted levels of experiential state-identity: Gross, Subtle, Causal, and Nondual (i.e. the modes of existential awareness, or bases of psychological operations). Along a vertical axis they plotted the levels of (ego-) self-development as described in this text.

The point being that the two dimensions are independent – one can achieve any of the state experiences in any of the developmental levels – but one's *interpretation* of that experience will depend on the complexity capacity and psychological sophistication appropriate to their developmental level. For instance, a pastoral nomad in medieval Europe (Magic), a Christian fundamentalist in 18th century France (Mythic), and a Wall Street executive (Rational), could be given the same instruction, and in practicing the same way, experience the same state of formless awareness, and perhaps even mature it into a basis of operation or experiential mode. Despite sharing the same state/trait experience, the individuals would likely interpret their experience in completely different ways.

Though Wilber focuses on the primordial states mentioned in eastern traditions, i.e. waking, dreaming, deep sleep, etc., we will use a more extensive meaning of "state." Simply put: a state is an experience. It is what is happening in the moment, and from a neurological perspective is about what is *firing* in the brain (in any moment). In contrast, stages are learned capacities, which from a neurological perspective, are stored in memory and are about the *wiring* of the brain (which changes gradually through learning, etc.). Put another way, stage are about structure and state are about activity (activation). The state experiences we are most interested in for contemplative essence psychology are those that can mature into stable "bases of operation" and which form important foundations for ego development.

Views (1) – state-stages. An important question is, what is the relationship between states and stages, and in particular, how does the experiencing of esoteric contemplative states (or "spiritual" states, flow states, etc.) effect one's stable traits? To a first approximation, the Wilber-Comb matrix argument is that there is *no necessary* relation – the state and stage axes are perpendicular, i.e. independent. But, clearly, contemplative practice does help people grow psychologically. Wilber does not say that meditation does not facilitate self-development, in fact he alludes to Alexander's research sharing that meditation can engage structural self-development as well as state-development: "In fact, meditation, can help move you *an average of 2 vertical stages* in four years" (Wilber, 2006, p. 137).

What we can say is that dedicated practices leading to state experiences can lead to *stable intentional/skillful access* to those experiences. And as any skill becomes mastered and used repeatedly, it eventually becomes internalized and normalized within the unconscious, so that it becomes automatic. Wilber and others have differentiated the trait changes (the modes of advancing or growing) associated with development from those associated with contemplative practice, calling the former states and the later *state-stages*. The Indo-Tibetan calls these *views*. One's access to a view matures from unstable access during meditation, to stable skillful access in meditation, to stable skillful access in everyday life, to becoming an automatic "basis or mode of operation" within normal cognitive processing.

Though to a first approximation (Wilber-Combs model) states and stages are independent, actually it is more accurate to say that certain stable state-stages are *necessary but not sufficient* for acquiring certain stages (see O'Fallon in this issue and Darrall-Rew & DiPerna, 2016). A number of writers (including Wilber, 2017; O'Fallon, 2016; DiPerna, 2014) have clarified that the state-based process of *waking up* is not necessarily the same as the stage-based process of *growing up*. All these theorists agree that access to, and the stabilization of, the higher stages of structural cognitive development are dependent upon the access to, and stabilization of, deepening degrees of metacognitive modes of operations.

We continue our conversation of view below at "Views (2) – as bases of operation." Next we explore the question: what processes are involved in creating these state-stages or views?

Unlearning, Disembedding, and Liberation

Unlearning: constructive vs. deconstructive growth. There is a prevailing opinion, implicit or explicit, that the later states of growth in psychological maturity and complexity necessarily track with later levels of spiritual or contemplative realization. However, suspicions that the two are actually distinct have been deep in recent times, with the many disappointing, and to some shocking, stories of "awake" or "enlightened" spiritual teachers who have committed moral breaches or other severe errors of judgment (Arterburn & Felton, 2001; Bell, 2002). Deep spiritual states don't necessarily lead to practical wisdom. The Wilber-Combs principle that states and stages are distinct explains this in part – but there is more we can say about it.

The difference between spiritual growth and cognitive growth is clarified in noting that cognitive development is mostly a process of *additive* growth, while most contemplative practices aim, in part, to *deconstruct* cognitive conditioning (McKee & Barber, 1999; Murray, 2018). Let us consider the importance of deconstructive learning, or *unlearning*.

As noted by developmental theorists (see section 2.2), the maturation of human cognition involves the accumulation of concepts, skills, and perspectives over time – through processes of differentiation (perceiving ever more nuanced differences and details) and integration (conceiving of ever larger gestalt wholes and general concepts). These build up hierarchically, layer upon layer, from sensorimotor operations to concrete thinking and then "formal operational" abstract thought and beyond. Each piece of learning can be thought of as both a new tool that creates fresh capacity and *opportunity*, *and* a new binding or set of associations and assumptions that *constrains* the possibilities of future thought and action. For example, learning how to ride a bicycle or do multi-column multiplication creates new capacities; but also, as these skills are practiced and embed themselves into lived experience, learning them tends to make it less likely that one will learn and experience alterative ways. Beliefs about the self and skills associated with one's sense of self are particularly resistant to change and adaptation. Experiencing alternate approaches often requires *unlearning* and disembedding from learned patterns and assumptions (see Murray, 2019, on "unknowing"). One must often free oneself from the old to make space to constructing the new. There are obvious examples where unlearning is called for, for instance, when one comes to believe that one is not good at math, or that people on the other side of town are not to be trusted – but the applications of unlearning are broader than is usually recognized.

Hierarchical complexity models of development in the Neo-Piagetian schools (including Commons, Fisher, and colleagues) deal primarily with additive growth. While ego development (Loevinger, Cooke-Greuter, O'Fallon, and colleagues) differs in that it includes both additive learning and deconstructive unlearning. In ego development each unfolding stage of cognition (sensorimotor, preoperational, concrete operational etc.) leads to a metacognitive application of that level of intelligence towards the internal world of the psyche. This allows one to see the limitations of prior learning and either contextualize the prior learning by transcending into a wider perspective, and/or correcting or dismantling the prior learning. Both moves lead to new modes of freedom and choice.

Disembedding – self from content to context. As we have indicated, in many contexts in order to learn something new one must unlearn an existing structure. More precisely, what is usually needed is to *distance or disembed* oneself from the prior structure to clear away sufficient clutter and open up cognitive and behavioral space so that one can experiment with new objects and configurations of thought. This inhibits interference from habitual patterns that would crowd out the growth of new patterns. After the new learning is well established, one can then choose to revisit and *integrate* the old way with the new way, expanding the options available to respond to diverse contexts. In sum, unlearning is *disembedding from, not erasing*, prior cognitive conditioning.

In fact, the life-long process of ego (and meaning-making) development involves perpetually *recurring* phases of learning and *unlearning*. For example, to advance into formal operational thinking must critique, deconstruct, and/or disembed from conventional thinking and assumptions; while moving from formal operational to post-formal operational likewise involves dissembling from many of the assumptions of formal operational thought. Learning and unlearning occur at, and define, each major junction of development.

Creating this cognitive distance amounts to taking a broader perspective on prior conditioning, as in Kegan's process of reflectively turning subject into object – we come to see and evaluate a part of ourselves that was previously hidden. The ACT model (Hayes, et al., 2013) describes this as a shift in psychological operation from *self as content* (i.e. from fusion with a conceptualized narrative of self) to *self as context*, in which one operates psychologically as the observing self.

The pre-differentiated phase of cognitive processing is described as cognitive fusion or embedding. The term defusion (or cognitive defusion, Hayes, 2011), is another term for this process of constructing a part of the self that observes (reflects on) another part of the self. It is also known as disembedding, de-reification (Dorjee, 2013), reperceiving (Shapiro & Carlson, 2009), decentering (Safran et al., 1993), deautomatation (Deikman, 1982), and detachment (Bohart, 1983).

Thus, as an infant grows into childhood there is both a growth in the increasing complexity of cognition and affect, and simultaneously a greater degree of being able to defuse from the objects of experience at ever deeper or more entrenched layers of the psyche. Ideally, over a lifetime this leads to greater freedom and simplicity. Unlearning can also be thought of as a letting go of, a liberation from, a seeing-through, or a deconstruction of some aspect of the self or meaning-making apparatus, and in so doing opening to a wider view of reality (and self) that is not constrained by that conditioning. "*Insights*" develop through or leading into this wider space. Insights can include deconstructive revelations that "[such] is actually not (necessarily) true," and *constructive* knowledge that "therefore [such] is (possibly) true."

Phases of development are represented in the STAGES model through its articulation of the *receptive* (passive)*, active*, *reciprocal,* and *interpenatrative* phases of each tier. Each phase involves a different type of metacognitive process. The receptive phase occurs when one has disembedded from the prior world-view, creating enough distance to open to new types of objects in awareness (related to Kegan's subject-to-object process). At first the learning task is simply to recognize these objects (raw awareness). Further development (active) leads to the ability to compare, contrast, and order them (and to a fascicle ability to experience arisings without being merged with them – detachment). Further development (reciprocal and interpenatrative) leads to the integration of the new knowledge with what was distanced in the prior worldview (assuming development progresses in a robust way). This process of progressively deepening insight shifts the individual from temporary states of functioning to possession of enduring psychological traits (i.e. from states to stages). This contemplative mechanism of being aware without mental engagement in the contents of awareness is central to the process sequence of: (starting with passive fusion), passive raw awareness, active and reciprocal differentiation, and interpenetrative integration drives psychological growth through all stages of ego development (Wilber, 2000; O'Fallon, 2013).

Levels of emptiness. Contemplative essence practices aimed at this goal are also called "*emptiness* practices" – i.e. the contemplative metacognitive practice of examining direct experience to recognize its constructed nature, as it matures through the stages of contemplative practice. First the student learns the *theory* (i.e. conceptual map), that everything one experiences is constructed by the mind, and decomposable into parts ad infinitum. This idea is examined conceptually as it relates to the objective and subjective worlds of experience. This cognitive understanding is then matured through a series of progressive metacognitive practices examining specific psychological structures. The examination proceeds in phases with the decentering of the: body, self, emotions, thoughts, time, duality, core beliefs, and attentional system.

Emptiness practices makes visible to awareness tacit assumptions that *construct* one's sense of self and understanding of world. To make these constructions objects of *awareness* is to motivate the *deconstructive* move of perceiving reality absent of them. The result is not necessarily as much a "truth" as a perspective one learns to take. That is to say, one does not so much discover that body, self, time, concepts, etc. "do not exist," but rather that the ways they appear to us are constructions of the mind. Thus "emptiness" in these traditions does not take the nihilistic meaning of knowing (for sure) that something does not exist, but rather indicates the freeing capacity to *choose* to perceive the world absent of certain assumptions or modes of conditioning.

Unlearning can happen at many levels. Learned knowledge, beliefs, and practical skills can be unlearned or re-framed when reflective metacognition shows them to be inadequate. Psychotherapy is usually a process of bringing to awareness, then evaluating, and then disembedding from, beliefs and learned habits that negatively impact our *relationships or everyday happiness*. The unlearning that is of interest to us here involves the even deeper cognitive structures that define one's sense of identify and manufacture the contents of one's familiar experiential field. Compared to western psychology, contemplative traditions provide a more precise map of the process of unlearning the *self-system and the perceptual system*, that subsist at more primitive/foundational levels of the mind. The meditative processes outlined by the traditions of mahamudra and rdzogchen support deconstructive insights into the constructed nature of reality (in perception, conception, and belief).

We can expand upon the notion that deconstruction (unlearning) can target specific levels of early/foundational development. Very early the infant learns to process the unintelligible buzz of sensory input to perceive individual objects *as* recognizable objects. At some later point one *constructs* one's perceptual "understanding" of time, and of space. Later one learns that, among this activity of perceptual objects and events moving in time and space, some are *mine*, i.e. those that I have control over and feel as *my* body. Later in the development of the self/ego one learns that images that arise from memory and imagination can be distinguished from perceptual images, i.e. one learns to differentiate the duality of the interior vs. exterior worlds (imagination and really begin to separate). Eventually the infant begins to learn that objects have *names*, and language and conceptual categories (classes defined by durable features) begin to form. Along this path one also learns that the feelings and needs one experiences are distinct from the mother's (i.e. that others have their own interiors, needs, and experiences), unmerging self from other to build the first steps into autonomy.

Each of the early constructions noted above are essential to human functioning. Yet each also locks one into a particular mode of perception, conception, and being, and becomes the unexamined unconscious ground from which one acts. Disembedding from each of these foundational structures has its own particular results. (Results which contemplative traditions valorize, but which might also be seen as hazardous for some individuals.) Each of these types of conditioning (learning) was constructed in its own time and level within the cognitive architecture. Different techniques may be needed to disembed from each of these (though some techniques will target more than one of them). The Indo-Tibetan traditions specialize in elaborating exactly such a diverse toolbox of methods, which the contemplative essence schools have attempted to coordinate them into a coherent system.[6]

---

[6] It is alto the case that individuals will differ on what method or "trick" works best for them to see through any given type of conditioning, and the traditions offer a variety of approaches to each goal.

Eastern scholars have contemplated this territory deeply, but modern cognitive science is also discovering much about the fine-grained sequences of acquiring these skills (in part through the study of infants and children, something the wisdom traditions did not do). It seems possible that specific contemplative practices and contemplative states can be mapped onto this progression of infant (and beyond) development. States and state-stages such as thought-free empty awareness, no-self, non-dual merging of interior and exterior realities, timeless presence, vast spaciousness of open awareness, etc. – can, theoretically, be mapped to specific layers of early cognitive processing being uncovered in cognitive science.

Supports for cognitive defusion. Into/Tibetan contemplative essence psychology and theories of contemplative metacognition prescribes a number of methods and principles for achieving/supporting the process of cognitive defusion (disembedding, etc.) at various levels of cognitive processing. Here we can draw from our tour of the literature on metacognition and contemplative practice. *Concentration* practices create focused awareness and inhibit distractions; and include attitudinal adjustments (e.g. equanimity) that support open awareness. For example, Hayes' ACT model includes “the creation of *nonliteral, non-evaluative contexts* that diminish the unnecessary regulatory function of cognitive events” (Hayes, et al., 2013 p.4). ACT (and MBCT) teach the client to come into direct experiential contact with the present moment (rather than being dominated by conceptualizations of the past and future) and, rather than attempting to alter the form, frequency, or intensity of cognitive experience (experiential avoidance), learn to accept it and be curious about it (Hayes et al., 1996).

We have noted that affective cognition is closely tied to the rest of cognition. For cognitive disembedding to serve its purpose in psychological healing and liberation, it must be accompanied by an attitude of acceptance (equanimity). If prior learning is rejected, distorted, or repressed without being re-integrated, this can lead to psychological dysfunction (Wilber, 2017).

In the psychotherapeutic disembedding from identification with dysfunctional experience such as maladaptive thoughts, negative beliefs, reactive emotions, and traumatic sensations, the client is able to develop perspective on their experience that allows for transformation. According to Yates (2017) mindfulness recodes the information from the object level so the dissociative processes of internal verbalization and defense mechanisms, which distract from immediate experience, do not distort it. This process of decreasing temporal dissociation reduces cognitive fusion (“the tendency to buy into the literal meaning of thoughts, feelings and bodily sensations” Herzberg et al. (2013, p.1)). This is supported by (Dahl et. al., 2015) research done on how the attentional practices of meditation stabilize the self-regulatory meta-level (Jankowski and Holas, 2011) of the metacognitive attention (Yates, 2017).

Views (2) – as bases of operation. Picking up our discussion of view from above ("Views (1) – state-stages"), the concept of *view* is central in mahamudra. *View – tawa (Tbt.)* or *dristi (Skt.)* – literally means the view from which one experiences phenomena. We mentioned above that a view is a stable state-stage in Wilber's terminology. Though some treatments focus on one particularly significant state-stage, noting that establishing "the" correct view is an essential milestone, we will speak of views in the plural.

Above we mentioned how cognitive defusion (unlearning, subject-to-object shifts, emptiness practices) help *establish* a view. But what exactly is a view? In the most general sense, views are modes/levels of *perceiving* the world, while stages are modes/levels of *conceiving* (making meaning of) the world. The developmental stages of meaning-making (and ego development) are largely about what one can see, recognize, reflect upon, and contextualize – primarily manifested through language. This constitutes an *explicit conscious* capacity to demonstrate understanding of something using one's conceptual apparatus. A view is more perceptual than conceptual, and does not require verbal elaboration to be achieved. Referring to our distinction between meta-knowing, meta-sensing, and meta-thinking, the view is a type of meta-sensing. We might also say that a developmental stage involves *focusing in* to "grasp" an object, "peer" into its details, and "link" it with other objects as a larger whole; while a view is a capacity for *open awareness* that steps back/out to take in the whole as a field, and forms a ground or space of potential within which objects can arise – perhaps to later be grasped (focused on). (Though practices that help *establish* a view will also use focusing practices.)

The different layers of cognitive processing noted above imply a differentiation (perhaps even a hierarchy) of views. Contemporary psychological models of metacognition and contemplative practice talk about views, but have yet to fully tap the knowledge within contemplative essence traditions. For example, Dorjee’s (2013) model explicitly acknowledges the need to better articulate the progression of views, which they call "modes of existential awareness," which come from the increasing degrees of de-reification achievable with contemplative practice. Our analysis here argues that views are more adequately defined by what layer(s) of perceptual/conceptual habits of mind have been *deconstructed/disembedded* than by a hierarchically built-up capacity. The more advanced "higher" views come from more flexible/free bases of operation at *deeper* layers of cognition.

Brown (2017) explains that the view is dependent upon the basis of mental operation (spod yu), the loci of identity, level of awareness or vantage point from where the mind’s metacognition is operating. In essence practice the meditations are less about meditating on something as they are about learning to operate from a new level of awareness, a new basis of operation, and from there to take a new perspective or view on experience. The process of contemplative development as outlined in the essence traditions is a metacognitive process of learning to shift the psychological basis of operations to deeper and deeper levels of awareness.

One's access to a view matures from unstable access during meditation, to stable skillful access in meditation, to stable skillful access in everyday life (when one consciously chooses it), to becoming an automatic (natural) basis or "mode of operation" within normal daily cognitive processing. As awareness becomes liberated from confused identification with the contents of consciousness it is eventually is able to recognize "primordial" aspects of its nature. With each new basis of operation, a field of new types of objects (phenomena) is available to conscious awareness. As in O'Fallon's receptive phase, at first this new field may seem empty-yet-pregnant, or vibrant-yet-elusive. But, with practice and time, new types of objects take form, and are seen to arise clearly within this newly expanded field, and can be objects of reflection, comparison, manipulation.

Mind vs. Event Perspective (figure and ground in contemplative practice)

Let us return to an aspect of metacognition mentioned in Tashi Namgyal's (2006) elaboration of one taste yoga: the mind perspective vs. the event perspective. Each basis of operation (state-stage or view) has the capacity to view phenomena (or content, i.e. taking the event perspective) and has the capacity of self-recognition (through metacognition, i.e. taking the mind perspective). The *event perspective* refers to the perspective of mental objects perceived at that particular level of awareness i.e. concrete objects for the concrete tier and subtle objects (such as thoughts) in the subtle tier (and awareness itself for the metaware tier). The *mind perspective* refers to the perspectival capacity to self-reflect on subjectivity and recognize the level of awareness from which the mind is operating.

In One Taste Yoga, establishing the view involves exploring the timelessness of the spacious phenomenological field of perception, and then recognizing the nature of the awareness that perceives such a field – thus shifting from event to mind perspective. Tashi Namgyal (p. 225) lays out three stages to the actual identification of the spontaneous coemergence: “When the meditator perceives the clarity of perceptive form and its unidentifiable emptiness as being the inseparable, denuded union of appearance and emptiness or emptiness and appearance, he has gained insight into the intrinsic coemergence of appearance” (p. 233). Brown (2005) calls these mind-simultaneous, cognition-simultaneous, and appearance-simultaneous views.

The complementary abilities of *focusing* attention on specific details or parts, and *open monitoring* of the perceptual field (i.e. zooming out to see contexts and wholes, like scanning in peripheral vision) have been identified as primary or core cognitive functions (Ainsworth et al, 2013; Fujino et al, 2018; McGilchrist, 2019). Open monitoring is not necessarily open to all phenomena in the moment, but is a vigilant yet relaxed seeking for any phenomena within some bounds (called "still hunting" by Bonnitta Roy – personal communication). For example, one can open one's perceptual field to awareness of "all moving things," "all red things," "all sounds," or "all thoughts" that might arise in any moment (opening to *every* phenomena arising in any moment is quite difficult and perhaps impossible, but see, for example, Shinzen Young's "cross training" methods of opening to inner sight, sound, and touch separately and then in a coordinated fashion (2016a,b)).

The mind perspective adds an additional shift to this open monitoring. It moves from the outward-facing open monitoring to sensing the subjective field itself – a figure-ground switch like seeing the frame holding a picture, which is very close to, or yoked to, the inward-facing sensing of the organ of perception *of* that field. In the still-hunting of the deer hunter, one maintains a relaxed open gaze anticipating movements that might reveal the prey. But it takes only a slight sift of perspective to notice the open field itself, which in this concrete case means the expanse of grass and shrubs, moving slightly in the breeze, covered by open sky; and another slight shift to feel into the *nature* of that open space – e.g. its expansiveness, the lushness of its texture, the warmth of its color pallet...; and yet another slight sift to become aware of the looker (the hunter) and notice these qualities as qualities one is feeling coursing through one's body; as a still point of observation that is both apart from and a part of the field.

In the case of contemplative practice, the shift is to noticing that some "I," or awareness-looking-through-my-eyes, or awareness-itself (perhaps just different meaning-making metaphors for the same phenomena) is *doing/being* something that is experiencing the phenomena. (The event-vs-mind perspective shift can be demonstrated at the *concrete* level by shifting from feeling/exploring an object, say a pen in one's hand, to experiencing the hand from the inside *as* touching/feeling/exploring the pen.)

The application of these core processes of focused awareness vs. open monitoring (and event vs. mind perspective) reiterates through developmental tiers, first within sensory-motor perception of the *concrete* world, and later with ability to metacognitively direct thought itself in the *subtle* tier. (At the *metaware* tier the process reiterates with a deeper awareness of the mind-body system as an integrated whole, including apperception of aspects of the unconscious revealed through somatic signals, and an awareness of awareness itself.)

The STAGES model can be used to tie this aspect of mahamudra to developmental theory. STAGES posits that each developmental stage starts with an exterior (other-oriented) orientation and matures to interior (self-oriented) orientation. STAGES scorers can distinguish "early" vs. "late" phases of any of the 12 levels by assessing the exterior/interior dimension within language cues. We suggest that the exterior orientation can be mapped to the event perspective, and the interior to the mind perspective. In this treatment mahamudra informs developmental theory by adding details about the practice of mind-vs-event perspectives; while developmental/cognitive theory informs, or empirically confirms, the mahamudra model.

Psychological science indicates that self-understanding is often preceded by understanding of the external world. For example, I child learning about the concept of anger (concrete) or prejudice (subtle) will see it as a negative characteristic of others well before seriously considering "am *I* prejudiced [or angry]?" As Forman notes: “All the stages of identity development, therefore, rely on different forms of outer-directed cognition eventually being used in the inner world of the self” (2010, p. 80). Similarly, STAGES proposes that new objects of awareness are recognized outside the self first, and within the self later – i.e. that exterior awareness precedes interior awareness, and that this pattern iterates for every developmental fulcrum.

Here we should clarify what is meant by exterior vs. interior, which is actually, as Forman calls it, outer-directed vs. inner-directed, or about you/they/it vs. about me. I.E. this is *not* a classification of objective (or 3rd person) phenomena vs. subjective (first person) phenomena, since one can be thinking about both the behavior (external or concrete) *or* the cognition (subjective or subtle) of another person (vs. oneself).

The outer-vs-inner directed (exterior-vs-interior in STAGES terminology) maps directly onto the event vs. mind perspective in mahamudra, if we treat exteriors as the content of perception/cognition and the interior as the metacognitive process of becoming aware (making object) that mental content or process. Logically the content must come first – one must be able to notice objects in the field before scanning the field itself for possible instances of those objects.

In the inner-directed phase of each developmental fulcrum the individual is using the sophisticated cognition that they have developed in cognizing about the *exterior* world, and are now directing that cognition towards the *self* in the form of metacognition. This process then re-formats the self-structure according to the new higher order cognitive actions. As such, each level of cognitive complexity has an associated level of metacognitive complexity, and a new understanding of the self-structure. (This also implies that the notion "going beyond the self" is ambiguous, since what one identifies with shifts at each level, into ever more subtle and decentered phenomena.)

In contemplative essence practice a toggling is apparent between the object and subject, as well as between the event perspective and mind perspective. For instance, during the process of developing attentional capacity the practitioner begins by developing the ability to stay on an object from the event perspective. Once stability is developed the meditator learns to switch perspectives and meditate from the mind perspective on the inherent spaciousness, non-reactivity, lucidity, and knowingness of awareness. (To say it another way, one shifts from the content of experience to the meta-cognitive contextual awareness of the experience.) When the aspirant begins to study emptiness he or she would also first come to understand emptiness through its application in the analysis of everyday objects, the most common approach being Chandrakirti's sevenfold reasoning (Pianka, 2009). Once one has the conceptual understanding that the human body, a car, etc. can be broken down into innumerable parts, none of which constitutes a *body*, then that same analysis can be non-conceptually applied in meditation to the self-structure leading to a recognition of a level of awareness beyond the self. This same pedagogical process of focusing first on the event repeats itself to support the recognition of the space-like nature of awareness during one-taste yoga, and the recognition of referenceless awakened awareness during non-meditation.

In the next section we will illustrate the interplay of mind vs. event perspectives sequence over several levels (3.0 to 6.5).

Summary: Repeating Patterns

We have noted several inter-related processes that repeat or reoccur periodically through the entire developmental sequence: (1) the movement from receptive (passive) to active to reciprocal to interpenetrative modes; (2) movements of learning, unlearning (or disembedding), and re-integration; (3) the movement from state experiences (first as glimpses and later at will), to steady automated state-stages or views (which create awareness capacities that enable particular fulcrums of development); and (4) shifting between event perspective and mind perspective (mapping to STAGES outward/exterior vs. inward/interior focus).

From the metacognitive literature we can also note (5) the interplay of attention and intention (as attention to intention, and intention on attention). Once metacognition brings the nature of this interplay into awareness, one can de-activate the processing involved in attention and intention to develop choiceless awareness (just sitting) as an automatic, natural process.

We have also noted, from the STAGES model, (6) the pattern of growing from understanding individual objects to collective objects, which can also be understood from MHC (Commons' and Fisher's theories) as increasing complexity from the awareness of objects in isolation, to perceiving relationships between objects, to seeing ever more complex systems of objects, to having those systems so fully integrated that a new whole emerges at a new level. Within the contemplative psychology of the Mahayana this shift from individual to collective relates to the shift from an individual and personal experience of awakening to the recognition of the universal interconnected and interdependent matrix of reality that is a collective. It is a shift from an apparently awakened 'me', to an awakened 'we'. This shift in realization has a profound implication to ethical and moral behavior as the individual realizes that their personal spiritual unfolding actually co-arises and is inseparable from the spiritual unfolding of the larger social body and by extension all sentient beings.

All of these patterns are described in the scientific psychological literature in terms of basic functions of the mind, and they are present in the Indo-Tibetan contemplative essence tradition through practices meant to support human liberation. This tradition elaborates, in successive levels, the metacognitive refinement of psychological insight into the constructed nature of human experience; and does so with practice injunctions that support the experience and embodying of these states and stages, vs. the mere objective (disembodied, conceptual, theoretical) understanding of them.

3.3 Levels of Developmental and Contemplative Growth

In this section we shift from describing repeating or iterating patterns of developmental capacities and practices to describing capacities and practices as they *differ* across the spectrum of levels. Here again, the contemplative essence tradition can be seen to coordinate well with modern psychological and cognitive theories.

Tiers: Gross, Subtle, and Causal

We will start with the large-scale structure of development, sometimes described as a progression of "tiers," and we will later discuss finer grained phenomena per level (by stage). As mentioned above, standard western psychology has elaborated on the significant movement from concrete operational to formal operational thinking, where the latter includes the adult capacities of abstract and logical reasoning. These shifts can be seen as emergent leaps in the types of objects that one can be aware of (and thus coordinate and manipulate). Fischer's Skill Theory refines the idea to specify these tiers: sensorimotor operations, representations, abstractions, and principles – where the first two are concrete operations, the next two are formal operations (Fisher, 1980). Common's model adds a higher tier for paradigms, making way for "post-formal" and post-post-formal operations (Richards & Commons, 2002).

As has been described, these models map cognitive complexity alone, while ego development models include the application of complexity capacity to the *interior* domain of the self, or the domain of the ego-involved, and thus describe processes of unlearning and disembedding that map transformations of the whole self, opening up ever wider fields of perspective and state-stages of awareness. (Remember that this describes the ideal case, in which increasing heights of complexity coordinate with increasing depths of state-stage development – while, in less than ideal, yet common, cases height and depth can develop separately, as noted in the Wilber-Combs principle.) O'Fallon's Concrete and Subtle tiers map to the concrete and formal operations and of other models, and she adds a post (or post-post) rational tier called Metaware, in part influenced by Wilber and his descriptions of the spiritual aspects of the post-rational territory.

Wilber's and O'Fallon's models are strongly influenced by eastern models, which describe three fundamental tiers: gross, subtle, causal. Drawing on the Indo-Tibetan tradition, we can expand this to include four levels:

- The *coarse* (or gross) level of mind, which has a basis of operation of awareness fused with body, thought, and self structure, and is also the foundational metacognitive mode of the concrete tier of development (STAGES Concrete tier, 1.0-2.5). O'Fallon extends the mahamudra notion of View into the lower tiers, suggesting that developing View at this tier involves the ability to simply *focus attention* on concrete objects (individual and collective).

- The *subtle* level of mind, which has a basis of operation of awareness beyond the self-structure, and is the foundational metacognitive mode of the subtle tier (STAGES Subtle tier, 3.0-4.5). According to O'Fallon, the basic View of this tier involves the ability to focus on the objects of thought, including subtle feeling states.

- The *very subtle* level of mind, which has a basis of operation awareness beyond temporal/spatial processing, and is the foundational metacognitive mode of the metaware tier (STAGES Metaware tier, 5.0-6.5). For O'Fallon, the view at this stage can also include awareness of the meaning-making process happening in real time (leading to construct awareness).

- And, the *awakened* level of mind, with a basis of operation beyond informational processing of the intentional/attentional system, and which is the foundational metacognitive mode of the unified tier (STAGES Unified Tier, 7.0-8.5).

Seen through the STAGES model, contemplative psychology provides the theory and means for recognizing the bases of operation that are the foundational identities of the higher tiers of development (metaware and unified) necessary for advanced adult development. From the perspective of Indo-Tibetan essence psychology, contemplative practice focuses on the knowledge and skills to support the recognition of new contextual existential modes of awareness, basis of operation, and the integration of perceptual and mental content into those basis of operations. As seen in Table 1 below, the direct relationship between the tiers of development, levels of mind, and basis of operation allow for a potential theoretical integration of these theories.

Table 1. Tiers of Ego Development, Levels of Mind, and Basis of Operation.

Tier of development	**Level of Mind**	**Contemplative Bases of Operation**
Concrete	Gross	awareness fused with body, thought, and self structure
Subtle	Subtle	awareness beyond the self-structure
Metaware	Very Subtle	awareness beyond temporal processing
Unified	Awakened	beyond localized informational processing of the attentional system

Concrete and Subtle Tiers – practices and capacities

1st and 2nd PP religion and practice. When eastern spiritual and contemplative teachings were brought to the west in the mid-twentieth century they were somewhat distorted – modified to suit western cultures, and perhaps also biased because of common characteristics of eastern teachers who would be drawn to teach in the west, leaving their cultures behind. What was generally lost is the importance of foundational practices within what we would here call the concrete and tier (and also but to a lesser degree, the subtle tier). Spiritual seekers and contemplative enthusiasts usually imagine they seek some state or stage beyond the norm. Though spiritual and contemplative practices almost universally reiterate traditional teachings about ethical and physical foundations, it is easy for these to become attenuated in western culture – as if "we already have that taken care of," when in fact, the opposite case could be made that it is in the ethical sphere and the early psychological "attachment" domain that the West is most lacking and/or pathological. That being said, many are indeed inspired by the ethical principles and moral narratives brought from the East; and body-based yoga practices have obviously proliferated in the west.

As in other religious traditions, most followers/practitioners of Buddhism live in simple pre-modern contexts and have infrequent opportunities to develop abstract thinking skills. Even for the minority who studied in monasteries, where intellectual rigor was taught, the opportunities for exposure to diverse perspectives was much less than that afforded by the modern world with its communications and transportation technologies.

Meditation in itself is not seen as enough to facilitate the kind of integrated growth necessary for the training an awakened mind. Foundational features that we would associate with concrete or conventional modes of thought accounted for the bulk of religious engagement for most traditional practitioners. These include: story telling; rituals; the repetition of movements, words, or sounds; simple actions of service and devotion; and numerous rules and principles defining an ethical lifestyle (prohibiting lying, stealing, killing, etc., and encouraging pro-social attitudes). At this foundational concrete level of understanding Buddhism also offers a number of tools for tuning the *attitude, motivations,* and background *knowledge* of the practitioner so as to support the central goals of skill-building, mental purification, and insight generation. Examples include: the charnel ground contemplations of inevitable sickness and death; and invocations calling for the guiding support of ancestors or etheric teachers. Within Indo-Tibetan schools, the Khrid system from Bon rdzogchen prepares the mind for emptiness practices through methods including contemplating impermanence, setting clear intentions, and mentor-bonding.

The above apply to ordinary followers and practitioners. Those in charge of the more rigorous studies of the monastery sternly enforced ethical rules and concrete behavioral injunctions, as prerequisites to more esoteric practices. Though, surely, there are exceptions, this level of concrete-tier rigor contrasts greatly with how, in the contemporary west, "almost anyone can walk off the street" and plunge deeply into a contemplative practice program. The west also tends to lack the rigor of the custom-based teacher accreditation/legitimation methods maintained in the east – allowing for many teachers with questionable foundations who "hang the shingle" advertising their gifts. (Of course there are many exceptions in the west to this low bar for student entry and lack of teacher certification rigor.)

Contemplative training has been historically undertaken within the larger context of a monastic liberal arts education that included study and intensive retreat experiences. In the sub-section on "omniscience" above we noted that, along with metacognitive (meditative) training, Indo-Tibetan Buddhist education emphasizes *cognitive* training comprising knowledge in ten fields (that can be summarized as: logic, language, medicine and healing, the arts, and the Buddhist science of mind).

All this is to say that, when considered from its indigenous context, Buddhist contemplative frameworks were *well aware* of the necessity of concrete operational (1st PP and 2nd PP) thought and associated behaviors as the prerequisite foundation upon which formal-operational domains (3rd PP) were built – even though one might think the concrete operational considerations were lacking by observing only western instantiations of eastern practice.

3rd PP skill-building – metacognition. Contemplative traditions also directly support 3rd PP capacities in two forms: *metacognitive* thought and abstract *theoretical* knowledge. Formal operational thought includes the metacognitive capacity to monitor and think about one's own thought processes. It also includes the *logical* reasoning capacity for causal analysis and self-reflection, which in contemplative contexts is essential for developing an understanding of the cause and effect of the pervasive reactivity characteristic of the undeveloped mind. These combine to produce skills such as reflective thinking, critical thinking, perspective taking, self-authorship, and self-directed learning.

The fundamental practice of honing one's ability to focus on concrete objects, such as a candle flame, a mantra, or the tip of one's nose, are *concrete* practices. Mindfulness practices that call for one to maintain focused attention on the interior world of thought processes and subtle body sensations correspond to *subtle* tier 3rd PP skills in the STAGES model. These processes can lead one to elementary insights into the emptiness of thoughts, beliefs, and egoic attachments (see the sub-section above on "Prajna: insight into impermanence, reactivity, no-self, and emptiness").

It is important to emphasize the significance of the fundamental cognitive skill of sustained attention that is developed in the tradition through the practice of calm/staying concentration meditation. The stages of meditation are a form of learning, and like all forms of learning the ability to concentrate on the topic at hand is primary to learning about the topic more deeply. The research undertaken into the stages of contemplative metacognition reveal that the Anterior Cingulate Cortex (Schoenberg et al., 2018), which is activated in states of heightened concentration, is engaged by intermediate practitioners when learning to stabilize the new existential modes of operation in one taste and non-meditation. The training of attentional capacity is therefore fundamental to moving into the stages of adult development associated with contemplative practice. Within traditional Indo-Tibetan practice instructions we can find correlates to all of the sub-processes of attention cognitive processes noted in Grossenbacher et. al., (2017), including disengaging, shifting, engaging, sustaining, monitoring, and scope modulation of attention.

First the student learns the theory that everything in reality is constructed, made of parts connected to other parts ad infinitum. This truth is examined conceptually as it relates to the objective and subjective world of experience (in other words they are given the cognitive map). This cognitive understanding is then matured through a series of progressive metacognitive practices examining specific psychological structures. As we said, the material is first understood in an outward-facing more objective or conceptual sense; and then applied to the inward-facing domain of understanding and transforming the self.

3rd PP skill-building – logical reasoning and theoretical knowledge. We noted the importance of abstract *theoretical* understanding about causal relationships and subtle interior processes. The theoretical knowledge needed to authentically practice the mahamudra or rDzogchen essence psychology would include at least the following:

- knowledge of causal (Hinayana), systemic (Mahayana), and (essence) metasystemic levels of analysis to understand the causes of individual and social suffering and happiness,
- basic knowledge of how individual psychology, personal health, and the outer environment effect learning and practice,
- knowledge of motivation and its development from an individual focus on peak performance to the full maturation of the heroic altruism seen in the bodhisattva,
- the knowledge of the importance of character strengths and their development, and the self-knowledge needed to recognize personal character strengths and weaknesses,
- a pragmatic understanding of contemplative Buddhist psychological models of mind (attention, eight consciousnesses, levels of awareness, mental structures, etc.),
- understanding of the theoretical map of the contemplative journey,
- knowledge of the theory and developmental stages of practices for visualization, concentration, mindfulness, insight, energy cultivation, dream and sleep yoga, and essence practice, and
- the knowledge of the interaction between the practices and the possible aberrations of the practices.

Rudimentary versions of most of these ideas can be understood by concrete thinking. It is also true that more advanced forms of understanding them can move beyond the linear cause-and-effect, and strictly hierarchical relational structures of 3rd PP thinking into co-definitional, interpenetrative, ecological, and holographic structures understood by 4th PP cognition.

4th PP capacities. Because of the previously mentioned differences in the contexts of pre-modern vs. modern cultures, there are marked differences in how each person perspective manifests itself in traditional eastern vs. modern western contexts. *3rd PP* skills in traditional (here eastern) cultures were more limited to advanced study, as in the monastery, or among the well-to-do, or to highly cosmopolitan regions having a constant influx of alternative perspectives. Because the development of modern science and technology has required a sizable infrastructure including robust cross-fertilization of ideas and the efficient production and transportation of materials, and a work-force supporting all of that – all missing in traditional cultures – 3rd PP formal operational thought in traditional Buddhism took the forms of rigorous logical analysis and highly abstract concepts and models *without* including the "scientific method" presumed to have given rise to modernity. That 3rd PP cognition is more the norm in modern society implies that a higher percentage of people are ready for deep contemplative training (vs. say, concrete level Buddhist religious dogma, beliefs and rituals). That being said, it may also be the case that the modern mind has a more neurotic and complexly dysfunctional psyche, with more incomplete 1st PP and 2nd PP foundations, which could either inhibit contemplative insight or, worse, produce dangerously distorted outcomes from contemplative practices applied without the proper prerequisites (as described above).

There are also differences in how *4th PP* manifests in traditional vs. modern contexts. 4th PP emerges, in part, from grappling with the *limits of the 3rd PP* worldview. We see that 3rdPP empirical science, technology, and logical thinking have created as many problems as they have solved – both the achievements and the calamities of modernity are pronounced, whilst the calamities threaten to destroy humanity and the entire biosphere. 4th PP is associated with deconstructing the modern narrative and its materialists, triumphalist, and imperialist overtones; and revealing the hidden habits of externalization, extraction, and short-term thinking that feed modern progress. In comparison, traditional cultures had only a hint of the havoc possible when 3rd PP thinking took control. Thus their development of 4th PP capacities was not only rarer (in proportion to the number of 3rd PP thinkers that could develop further), but also less well fleshed out.

In addition, the 4th PP worldview is spurred by the cognitive dissonance that occurs when one encounters perspectives and viewpoints different than one's own. As we said, though some monasteries and cosmopolitan centers were known as places where cultures and knowledge-systems intermixed, it was nothing compared to the rapid movement and confrontation of ideas possible today. In the STAGES model 4th PP involves understanding subtle *collectives*, which includes the ability to reflect not only on one's thoughts and others' individual ideas, but on whole *systems* of ideas (as well as interior systems of sub-personalities). It is the collision of entire cultures and world-views, seen not over the slow course of human migration and generational shifts, but in the immediacy of televised (and twittered) wars, class conflicts, and intersectional identity politics – that forces us to see the limitations of, not just individual ideas, but our deepest cultural and identify-forming tacit assumptions.

Thus the 4th PP mind begins to contemplate the movement and evolution of *collective* thought, in the form of belief-*systems*: memes, worldviews, identities, paradigms, etc. Following the STAGES model of exterior (outward facing) before interior (inward facing) learning, we first see the noxious assumptions within unexamined belief systems as *out there* in "the system" ("the man," patriarchy, capitalism, the military industrial complex, etc.), and only later begin to know that our own thinking is always inevitably constrained by tactic cultural and psychological thought-systems. (3rd PP can see how the individual thought *processes* cloud mental clarity, but is not yet thinking in terms of collective thought-*systems*.) 4th PP thought also sees how knowledge is *hermetically bound* and *highly contextualized* – i.e. the interpretation of any text, concept, or idea can vary greatly based on the cultural and historical background it is interpreted within. In sum, truths and beliefs are revealed as social constructions.

The above partially explains why traditional religious and spiritual cultures can seem ethnocentric, patriarchal, and over-confident from the contemporary (or post-modern) perspective. Given this explanation of how 4th PP thinking in modern times will differ from 4th PP thinking in pre-modern times, we can still note how 4th PP cognition is represented in Buddhist theory and practice. 4th PP ego development occurs when one applies 4th PP cognitive complexity capacity to the domain of ego or self-involvement (including self-understanding and relational understanding). As we said, 4th PP perceives complex systems of objects or ideas (including systems of interior parts/processes). It begins to notice not just the impact of *certain types* of thoughts, but the misfortunes perpetrated by *thought itself*, and by reason itself. 4th PP cognition is also well equipped for multi-perspective taking, as it sees the limitations inherent in all/any perspective (not just some perspectives). In addition, 4th PP can better tolerate paradox and uncertainty, a hallmark of flexible thinking. It can better see variables and relationships as interdependent, and conceptualize open boundaries between systems (Koplwitz, 1984).

We can postulate that Hinayana, the first turning of the dharmic wheel, roughly corresponds to the awakening of 3rd PP; and the Mahayana, the second turning, roughly corresponds to the awakening of 4th PP. Mahayana introduces notions of emptiness (of various forms) and non-duality, and many of its texts work specifically with paradoxes, which is another 4th PP capacity. For example "deep examination of the essence of mind through wisdom will reveal the mind in an ultimate sense to possess neither intrinsic nor extrinsic reality; it is without structure" (Namgyal, p.64). The doctrine of dependent origination concerns the massive (systemic) co-determination of all objects of awareness. Mahayana is also more concerned with the liberation of the *collective* than the individual (as in Hinayana).

4th PP opens consciousness to the conditioning of and limitations of the mind; but, until 5th PP is obtained, these realizations are usually conceptual and after-the fact. The insights about the constructed nature (the emptiness of) self and ego, beliefs and ideas, and norms and preferences – are obtained through post-reflection, and perhaps after conceptually understanding another's erudition. They are more likely to be applied to understanding or critiquing others, groups, or "the system," than oneself. At 5th PP these insights become perceptual, immediate, and deeply personal, as conventional reality and the scaffolding of the self begin to radically disintegrate.

Metaware and Unitive Tiers – practices and capacities

We have noted how 3rd PP and 4th PP world-views manifest quite differently in pre-modern vs. modern (and post-modern) contexts. One might think that this trend will continue into the metaware tier (5th and 6th PP). This pattern is not as noticeable in the metaware tier as one might think. This is because the main differences between the two cultures in the subtle tier have to do with the large differences between pre-modern cultures and contemporary culture (which is a mixture of modern and post-modern worldviews). *There are no* post-post-modern (or metamodern, or metaware) cultures; there are few if any fully post-post-modern (or metamodern, or metaware) organizations or groups. The metaware system of thought has not be realized by enough people, and has not been worked over and through in richly intersubjective contexts enough to have evolved any stability (even local stability) at the collective level (this is mostly true of 4.5/Strategist also). Therefore there are not any appreciable metaware *cultural* contexts or artifacts to influence one's growth into and through the metaware tier. Therefor there is actually less difference between the metaware mind in traditional Buddhist contexts vs. contemporary contexts (though there should still be *some* differences). Therefor, we will not try to explicate East/traditional vs. West/contemporary differences at the metaware tier as we did with the prior two tiers.

With a foundation in causal analysis (3rd PP), Buddhist contemplative thought then evolved from a reductionistic perspective on human suffering (abhidharma, higher teaching, 3rd PP), to a systems perspective (madhyamaka/middle-way, 4thPP), and then to a later metasystemic perspective (awakening, 5th to 6th PP) (Guenther, 1989; Wilber 2014; Brown, personal communication, 2017). (We can postulate the Buddhahood corresponds to the Unitive tier of 7th and 8th PP.) Each phase of the teaching is an expression of a cognitive paradigmatic shift in understanding human suffering and happiness and its causes – a turning of the wheel. These shifts map well to our modern understanding of cognitive development.

In relationship to the exploration of contemplative psychology it is useful to explain the four stages of the Metaware tier, the aspect of the STAGES model that most pertains to Buddhist psychology. Terri O’Fallon (2013b) describes that in the metaware tier the mind can begin to perceive both the fullness of objects and the emptiness of awareness itself (which relates to the event and mind perspectives). The process through the metaware tier is the process of eventually reconciling awareness and its object in a non-dual recognition.

Each of the four stages of stabilized metaware apperception have a different focus or object of awareness but all have a sense of awareness with a ‘fullness’ and ‘emptiness’ of the objects that arise in awareness as the silent eternal, infinite field of the Witness. As one moves through these four metaware stages, the emptiness-fullness poles and the witness-kosmos poles gently collapse into each other in a process that comes to completion in the theorized fourth unitive tier (O’Fallon, 2013b, p.6).

Based on Indo-Tibetan essence teachings, the processes de-reification (or decentering) of the constructed nature of reality, generated by contemplative insight, pass roughly through these phases: body, self, emotions, thoughts, concepts, time, duality, core beliefs, and the attentional system. The first four of these are associated with contemplative insights in the subtle tier, the next four from the metaware tier, and the final one in the (much more speculative) unitive tier. Drawing on contemplative essence theory, we can describe some of this territory below in terms of no-self, timelessness, spacious freedom, the non-dual state, non-meditation, and non-localized awareness, and bodhicitta.

No-self. The relativistic experience of the self is, from the perspective of the essence traditions, the beginning of recognizing the emptiness of the self. Beginning at a pluralistic consciousness (4.0) that recognizes the social construction of the self, the ability to recognize mental structures that have been fused with awareness (at 4.5), matures into recognition of the creative construction of language, meaning, and perception (at 5.0 and 5.5; Cook-Greuter, 2000; O’Fallon, 2010a). Such processes support a shift in perspective that leads to an experience of self beyond conceptual construction. This shift in operation happens by making the prior subject of experience (the narrative-content self) an object.

In terms of practice sequence, as mentioned above, in order to shift the self-structure to a new identity (self/oneself) of awareness beyond self-structure, the practitioner recognizing, through insight meditation, that the self is a mental construction. The meditator then concentrates on the recognition of awareness that reveals itself as being beyond this self-structure. This continues until this awareness beyond the self is established as a new center of identity, a new basis of operation (a new "self"). Once this basis of operation becomes stable the relative activity of the mind can be allowed to return but this time viewed from a different existential mode. The change of basis of operation does not just change the fundamental level of identity or existential mode, but also allows for the reorganization of one's perception of the self-structure (and also of time, as noted below).

Really understanding that the self is a construction allows for the re-organization of the self-structure and its personal narrative into a structure that appreciates its relative existence. As such the process of deconstructing the self-existent reified entityness of the self offers the opportunity for reconstructing a new self – informed by the knowledge brought about by the transition to a new identity/basis of operation. In the developmental theory outlined by O'Fallon this reconstruction of the self begins at 5.5 and deepens to completion at 7.5. After the passive stage of stabilizing a new metacogntive basis of operation at the metaware tier of the very subtle level of mind 5.0 and the unified tier of the awakened level of mind 7.0, there then follows a more active phase of reintegrating the active constituents of mind such as thought and imagination.

Emptiness of time. This developmental process into the metaware tier leads to a recognition that culminates in the experience of the temporal organization of reality being a mental construction. This does not negate the experience of time, nor the objective (seeming) dimensions of time described in science, but only negates its experiential subsistence. In essence practice the meditation on the emptiness of temporal experience opens up the recognition of a spacious field of timeless awareness as a new basis of operation, corresponding to developmental stage 5.0. This process of orienting toward the larger whole field and then integrating the parts within the field is fundamental to the essence contemplative path. Once there is a new basis of operation, the practice of one taste meditation begins as the meditator works to maintain this newly emerged point of view simultaneous to the ongoing everyday activity of thought, affect and mental imagery arising in the mind. The emphasis is still on learning to stabilize the field of psychological operations during this mental activity and not suppressing it.

In corollary to the Into-Tibetan framework, O'Fallon's research (2013), reveals that that the mind expands its phenomenological perception of time to a large historic time frame and planetary space frame at 5th PP, and then to an understanding of evolution in the eternity of time and infinite of space, an infinite cosmic evolutionary process, at 6th PP. At that stage of integrating context and content it is understood that eternity and infinity are content, they are vast constructions of mind within which the evolutionary process continues indefinitely. Within 5th PP understanding, the mind can intuit possible futures along the trajectory of open and infinite time/space. However, this form of intuitive knowing is still based on a subtle construction of time and space. Beyond this, at 6th PP, is an understanding of the unbounded and timeless unconstructed nature of mind. At this level of stabilized contemplative development the fullness of evolution is held in the openness of unbounded awareness as part of the individual's on-going moment-by-moment experience. Practitioners at this level of development report experiencing the unfolding of cosmic evolution simultaneous to a liberating freedom and compassion whilst engaging in the everyday activities of daily living.

Metacognitively this means that the self is experiencing and understanding itself at 5.0 to be an expression of a historic ancestral process. The individual recognizes from a timeless basis of operation that the self and the language used to describe the self has been constructed over multiple generations. This matures and deepens so that by 6.5, the end of the Metaware tier, the individual recognizes from a timeless basis of operation that the self is an expression of a cosmic evolutionary process played out on the stages of infinite time and space. These insights are not just cosmological musings, but are how the individual interprets and makes sense of everyday challenges. Just as the Great Law of the Iroquois held that all decisions should consider the next seven generations (140 years), at the level of 6.5 there is an ethical appreciation that each decision should consider the cosmological evolutionary process and whether decisions are reducing or increasing psychological, physical, cultural, systemic, and environmental suffering for the evolutionary whole.

Spacious freedom and the Non-dual state. When, through the deepening of purification caused by maintaining timeless awareness as a basis of operations, the coarse and subtle level mind with its concrete and abstract concepts quiets, the mind becomes non-conceptual, and the student orients to the field of spacious experience recognizing the non-duality between the awareness and the background spaciousness of the sensory fields. This realization of the spaciousness of mind opens the path of practice known as *spacious freedom* which relates to the 5.0 level in Stages. As this level of practice matures it opens the direct experience of interconnection and interdependence that are indicative of the authentic experience of compassion as understood in the Mahayana, a compassionate spaciousness that phenomenologically is experienced as holding all beings of the past, present and future in a deep motherly embrace. This parallels the metacognitive maturity of the Metaware tier flowering at 6.5 into a deep experience of the metaware community that exists as a timeless ‘we’.

At that point the practitioner then refines the recognition into the empty constructed nature of all experience and purifies the residual, hidden, deep and subtle core beliefs of the increasingly diaphanous self-structure. This purification leads to a natural non-dual state of timeless awareness-space without any artificial activity of mind and within which all mental activity arises automatically and naturally as empty open constructions.

Non-meditation and non-localized awareness. This natural state is then used as a foundation upon which to set up the orienting instructions of non-meditation (correlating with entry to the Unified tier, 7.0). Here the practitioner shifts his or her identity out of identification with the attentional system’s localization of individual consciousness and information processing to the non-localized, limitless basis of operation, and the existential mode, of awakened awareness. This is the establishment of a new phenomenological field of awareness, and, in order to stabilize this new level of development, as at the previous level of practice in recognizing the awareness empty of time, the identification with all the mental activity of the previous level needs to be left behind temporarily so that a new, and in this case, referenceless identity as unbounded, pristinely lucid awakened awareness, can be established.

Due to the lack of sufficient research subjects at or beyond the 7.0 stage, O’Fallon’s model is theoretical. However, the process itself, the recognition of a whole field, and then the integration of parts into the whole, is derived based on developmental processes that continue to iterate. Mahamudra non-meditation or rdzogchen cutting-through (khregs chod) meditation allows the shift in the basis of operation of psychological operations to awakened awareness which when stabilized becomes foundation for the Unified Tier of adult development. This involves the recognition of individual-informational-attentional system, as an empty construction. Initially, the stabilization of this basis of operation takes the forefront of experience, as the relative activity of the mind is less emphasized allowing for the familiarization with this new identity. Based on the re-occurring patterns at the first stage of each tier (1.0, 3.0, 5.0, 7.0) O'Fallon's model suggests that at the first stage of the metaware (5.0, very subtle) and unified tiers (7.0, awakened awareness) will have this passive (receptive) mode, which then transitions to more active (and reciprocal) modes as the new basis of operation is integrated with prior capacities and everyday living.

Unified Tier and Buddhahood. Here we move in even more speculative territory. In terms of the Indo-Tibetan path to liberation, once one establishes the views associated with awakening or enlightenment, one continues to work toward buddhahood by establishing these views in ever more mundane and challenging life contexts, and also by further purification of the mind toward complete freedom from prior conditioning (exhaustion). These steps are well documented though numerous Indo-Tibetan texts, so it is not this part of the path that is speculative, but rather the connections between it and modern developmental theory.

Here the practitioner deepens the strength of this realization by integrating into the new phenomenological basis of operation, through dream and sleep yoga, the deep habits of the unconscious substrate mind (this can begin in much earlier stages, but is probably required for advancing into the Unified tier). By developing the ability to maintain the basis of operation during the typically unconscious processes of dream and sleep the karmic tendencies created through identification during the life span, and deepest levels of non-awareness are transformed until all dream and sleep experience is viewed as an expression of awakened awareness. Once the process of dream and sleep integration is completed the waking sensory experiences and conceptual thought are integrated into the awakened awareness. At this point of development experience is an uninterrupted non-meditation where all experience automatically arises as *self-arising* and *self-liberating* (rang shar rang grol).

According to contemplative essence psychology, the process of realizing self-arising and self-liberating (rang shar rang grol) is completed when the storehouse of karmic tendencies – all unprocessed individual, ancestral, cultural, and racial conditioning–is released and exhausted (dharmadhatu exhaustion). When the conditioning is thoroughly purified (T. Sang) the basis of operation of awakened awareness becomes operational through all states, and the mind opens (Tt. Gyé) to the positive qualities of "omniscient wisdom."

Theoretically, from the perspective of Western psychology that looks at the content of experience and not the context (basis of operation), this process is a regression in the service of transcendence (Washburn, 1988), with a stabilized awakened basis of operation there is no longer any ego defense active in the on-going experience and all the unprocessed, repressed, disavowed psychological content that has accumulated over a life time can now be released. This is the automatic experiential/psychosomatic extinction of early childhood object relations, early traumas and the conditioning of perinatal experience (Grof, 1993). As the personal unconscious is released into awareness and automatically processed, then the deeper organizing archetypal structure of the mind begins to reveal itself as an unfolding process of spontaneous visionary experience known as thod rgal (Smith, 2016). At this level of mind, the underlying archetypal energetic structure of psychological reality reveals itself as non-dual with awareness.

In rdzogchen this non-dual archetypal creative expression of the nature of awareness is known as rol pa *play* energy, and is differentiated from the non-dual dgangs *elemental* energy of thought and fantasy, and the non-dual tsal *liveliness* energy that expresses itself as a supposedly external material world (Capriles, 2006). The fruition of this process, i.e. Buddhahood, correspond to stage 7.5, the full understanding of the causes of human unhappiness and the realization of the path of deep human fulfillment and happiness where all conditioned reified structures have been seen through as empty constructions, all accumulations of conditioned memories (karmic traces) have been released. This leaves the mind stainless (Tbt: tri med), allowing awareness to be self-sustained through waking, dreaming, and deep sleep states, and the flourishing of the 80 positive states of a developed Buddha mind dedicated to altruistic service of all embraced sentient beings.

Bodhicitta. As such the process of ego development is not just a progressive overcoming of the obstructions to one's true nature, but is the expression, distorted in earlier stages due to fundamental ignorance, of the nature of the unfolding intelligence of compassion. In a cultural environment dedicated to the education of the human heart and mind, such as one finds in the inner chambers of the monastic colleges, ashrams, caves and hermitage sites of Tibet, Nepal, or India, the growth of self leads to a corresponding growth in compassionate intelligence. The child learns to take increasingly complex cognitive perspectives, reducing narcissism and increasing the circle of concern to include family, nation, planet, and universe in a web of relationships. In the tradition of Indo-Tibetan Buddhism this is referred to as the unfolding of relative bodhicitta (T.by ang chub kyi sems), the compassionate motivation and the ensuing knowledge towards supporting the liberation of other beings. Absolute bodhicitta itself refers to the direct realization of the constructed nature of phenomena and the recognition of the nature of the mind. (Buswell 2013). When plotted on the map of adult development researched and theorized by O'Fallon, relative bodhicitta refers to the constructive development of the higher stages of ego structure, and absolute bodhicitta refers to the deconstructive realization of awakened awareness, the deepest and unconstructed existential mode (Dorje, 2016), basis of operation (Brown, 2017), or level of contemplative metacognition (Unified tier in the STAGES model).

Revisiting States vs. Stages: Necessary but Not Sufficient

Here we continue our discussion of states vs. stages from the earlier sections "State, Stage, and View" and "Mind vs. Event Perspective." Above we have been coordinating the views or stable state-stages of consciousness described in contemplative essence psychology with that levels described in developmental theory. This may seem at odds with the notion that states and stages are somewhat independent (the Wilber-Combs principle), but recall that, from O'Fallon, we claim that certain state-stages are necessary but not sufficient to certain developmental levels. As we have said, the Wilber-Combs principles is that one can achieve the views (and states) described by contemplative practices *without* necessarily having the corresponding developmental complexity or ego maturity. What O'Fallon adds is that certain meta-cognitive or contemplative states are *necessary pre-requisites* for higher stages of developmental complexity and ego maturity to unfold. In terms of the above discussion of the metaware tier, this means that one can have experiences, even stable state-stages (views) including egolessness, timelessness, and spacious freedom *without* needing to have achieved metaware cognition. But the converse is not true: i.e. certain stable state-stages (views) *are* necessary for the achievement of any developmental level (the particular prerequisite view *differs* according to the stage).

In fact, access and stabilization of higher contemplative metacognition does not require cognition complexity or ego development beyond a basic ability to follow simply follow instructions. As such, it is feasible for individuals to realize the fundamental nature of non-dual nature of awareness without much understanding of the process, a criticism often directed towards many contemporary spiritual teachers and adepts who are "self-realized" and yet are unable to build robust pedagogical environments for teaching others. In the Indo-Tibetan contemplative tradition this is similar to the concept of a Pratyekabuddha (Wyle. *rang sangs rgyas)*, a *solitary realizer*, or *intermediate Buddha*, who is realized and yet lacks the omniscience of compassionately motivated structural development to be able to adequate lead others (Rahula, 2000). As such they cannot function as realized teachers because they are unable to communicate and individualize the instruction of the cognitive and metacognitive knowledge and practices of contemplative development. This phenomena can be further be explained by giving examples of how it might manifest.

An "awakened mind" at 3rd PP ego development may show signs of overconfidence, egocentric biases, ethnocentrism, bullying, and lack of empathy. Having had state experiences of egolessness, timelessness, and spacious freedom, they may interpret them in terms of self-aggrandizement and power. They may describe these experiences mimicking the flowery language of the traditions, but not reveal any poetic, nuanced, or uniquely personal understandings of these state experience.

An awakened mind at 4th PP ego development may show signs of hyper-complex or abstract over-thinking. They may have a deep conceptual, experiential, and applied knowledge about egolessness, timelessness, and spacious freedom; but still exhibit evidence that they have unexamined shadow material, and blame others for the suffering that they co-create. They may be able to take many perspectives but still be a stickler about the meanings of words, not realizing how concepts are constructed with each context and thought. They may be preoccupied with metaphysical abstractions that seem to explain spiritual concepts, while lacking the embodied felt-sense of how subtle shadow operates within their own psyche.

In "States and STAGES: Waking up Developmentally," O'Fallon (in this issue) shares her preliminary model for how states (and views) interact with stages of development. She shares an "interpenatrative" model of how particular states or views are prerequisite to each stage; and how achieving a stage helps induce particular state experiences. O'Fallon's model is based on (1) close readings of a number of mystic-scholars, including Wilber, Aurobindo, and Diperna (who draws on Dan Brown's work); (2) empirical analysis of how words that describe state experiences appear over different developmental levels; and (3) anecdotal but substantial experience in working with individuals and scoring developmental assessments that represent the full range of adult developmental levels. The preliminary ideas we give here are compatible with O'Fallon, while not specifying as much detail; but we also aim to ground the ideas in the concepts described in this paper.

The primary novel feature of the STAGES model is that it sees the long arc of developmental levels in terms of patterns that repeat within each tier (and patterns that repeat within each level, which some other theories also have). It proposes that the same principals can be used to describe early, middle, and advanced development. As this framework encounters the contemplative traditions, it poses this question (among others): can those psychological/spiritual phenomena that we attribute to advanced achievement be described in terms of processes that are also at work for *childhood* through adulthood, and then into "sage-hood?" (and Buddhahood). Contemplative traditions included foundational (concrete tier) practices, but did not study childhood development; and they studied advanced states and vantage point but did not study advanced levels of cognitive complexity in the way developmentalists do. Combining these worlds provides hints into models that might give a unified theory of states and stages. O'Fallon has offered a significant if tentative step toward such a model. Below we show a condensed overview of how such work can be described in terms of the concepts we have explored in this paper. The main principles include:

1. Establishing a *view* (vantage point) involves appreciating some particular form of *emptiness* (e.g. of conventional rules and roles, thought, concepts, self, time, duality, or particularization). That is, to look deeply into a gestalt phenomena (object or process) that is tacitly assumed to be whole – it is so taken for granted that it is invisible to us ("is us"). With focused attention we discover that the gestalt has parts that the mind brings together to create the whole. In seeing the process of this construction, the phenomena is "deconstructed," and seen-through as empty. The question posed is: when is this particular realization of emptiness *needed* to address a pressing developmental dilemma?

2. *Developmental* stages are characterized by capacities (major skills like "object permanence" or "reflective thinking") defined by their level of hierarchical complexity. Skills and capacities begin as *glimpses* of new worlds of phenomena (e.g. classes of perceptions, durable objects, or abstractions) that need scaffolded assistance and motivational challenges to be developed into mastery. These glimpses are *state* experiences; and the nervous system often tags them with expansive or ecstatic "wow" feelings, which motivate the effortful process of learning (glimpses of new territory can also be disorienting). Eventually, with practice, comes mastery and *automation*, so that the skill becomes an unconscious tool that we rely on without thinking about it or feeling anything special.

3. *Ego*-development (the *type* of development we are most concerned about) stages grow when any mastered level of complexity-capacity is turned reflectively and applied to deconstruct some aspect of the *self.* (This deconstruction is only *part* of ego development; it also involves what one does *constructively* with the insights gleaned from deconstruction, as described below.)

4. Stage transitions are motivated by *dilemmas*. In particular, the capacity developed at any stage eventually *over-functions* and starts to become as much of a problem as a solution. To solve the problem it creates, the mind must develop a *meta-capacity* that can see the first capacity and critique it and modulate it. That is, the original mastered capacity is *tacitly used* to manipulate things according to explicit needs and goals, but there is nothing yet in place to explicitly (consciously) manipulate the capacity itself.

5. Each developmentally-induced dilemma is solved in the *subject-to-object* move that builds the meta-capacity to explicitly see and manipulate the original capacity. E.g. "thinking" moves from something one does without reflecting on it, and thus something one *is,* to something one *sees* happening and can thus monitor and control. When an aspect of the

self-system moves from "having" one to being "had by" (e.g. "I am not my thoughts") one is less *identified* or merged with it. It is seen as a part of the self-system but is not felt part of the self-sense (e.g. I have a body but *I* am not my physical body). The subject-to-object move creates a new world or *field* of processes/objects that were once tacitly assumed to be part of the self, and invisible. E.g. when thoughts can be "seen," a new world, a field of thoughts, opens up to learn about and eventually try to strategically control.

6. As one deepens understanding of a field and its varied contents, one can step back to see the field as a whole, and step back a bit further to notice the borders or boundaries of the field, and step back yet again to sense that which *holds* the field in its awareness. This is the *event-to-mind perspective* shift. One develops a felt sense of that larger meta-self, and becomes identified with it as the *new identity or basis* of operation – a new vantage point or view.

7. This vantage point begins the process anew, because it is something one identifies with – that one *is* – but is not yet something one "sees" and can control (as "object"). From the event perspective the new capacity is a new *skill* – a tool for operating on some field of objects to meet goals. From the mind perspective the new capacity amounts to a new *self* – one that holds that field. Also, at the beginning, this new skill/self appears in (usually exhilarating) glimpses, as an un-mastered ability (– so the process starts from the beginning at a new level).

The above is a very condensed overview of a longer narrative and emerging theory; and one that is not fully fleshed out yet. O'Fallon (2020) fleshes out similar themes in much greater detail. In sum: we have suggested how state experiences can lead to new stages *if* the right steps are taken. We have also suggested how stage transitions can *require* certain states – those states are necessary but not sufficient because the state must be applied in a particular way (self-reflectively) to achieve the stage transition.

We have also shown that, though each developmentally-created dilemma *calls for* a certain states/views, i.e. certain mode of emptiness, in order to be solved, that the state/view that can be used to solve a dilemma can be experienced *prior* to the developmental stage (unfolding) where they are "called for." This suggests that a deconstruction could occur before it was needed, and even perhaps before one was ready to appropriately use or integrate it.

State experiences can arise "naturally" in developmental unfolding, but can also be catalyzed by contemplative practices, hallucinogens and intoxicants, rituals or extreme events, etc. We can ask in each situation whether such a catalyst is a healthy support for a process already needing or "wanting" to happen vs. a forceful thrust into dangerous territory (a complex question depending in part on the type of "set and setting" support available). Furthering an earlier discussion, we can note several dangers of experiencing a state experience before the self-system feels an authentic need for it, or before one can integrate the insights that the state allows for. We list some of the dangers below (these items overlap with each other):

- *Narcissism*: If the state experience is not successfully applied reflectively to deconstruct an aspect of the self, the new capacity may be appropriated to narcissistic ends, as a more powerful tool with which to manipulate others, as opposed as a means for humble self-understanding.

- *Projection*: If the state experience opens up a territory that the individual is not developmentally able to make meaning of, the new "self" that emerges from the event-to-mind shift (e.g. witnessing consciousness) can be projected *out*, instead of being understood as a new self; and interpreted as, e.g. God, or collective consciousness, or some other metaphysical entity.

- *Grandiosity*: Alternatively, if the personality structure is too defended, or too naive, to "release" its hold in the deconstructive move, then the new view can be introjected inward and fuel grandiosity or ego inflation as in "I AM God" (or god-like).

- *Arrested development*. Ideally, the deconstruction of an aspect of self (a capacity) does not remove it or regress one to an earlier state, it allows one to see it (transform subject-to-object) and see it as constructed/empty (de-realize/de-center it). This gives one the choice/freedom/resilience to use a capacity more wisely. However, if the capacity is deconstructed *before* it is functionally *constructed* then a state-stage can result in a regression or the naiveté of a developmental delay. For example, when one "sees" that there is "no such thing as the self" before one has a functional autonomous ego, then one can regress into a pre-egoic state because one does not have the option to bring out the tool of a strong egoic-self strategically when it is needed.

- *Dissociation*: If the deconstruction/emptiness move threatens to reveal something about the self that the self (ego) strongly resists knowing, the state capacity many not be used to reflect upon the self; or if it does, the self may split, creating type of dissociation such as unhealthy "depersonalization" or "derealization".

- *Abstraction*: If one learns about or gets a taste of a state and does not allow the associated capacity to work, in an *embodied* sense, on the tacit and unconscious realms of the mind/body, it can continue to live in a world of abstraction (or hyper-abstraction), wherein concepts such as oneness, nonduality, emptiness, fullness, selflessness, and timelessness are disembodied concepts with a tenuous relationship to direct experience.

- *Attachment*: Finally, if one becomes "addicted" or attached to the experiential "wow" factor of novel states, and a hedonistic compulsion toward state experience (vs. a dilemma or desire to learn) is the primary motivation for inducing the state, then opportunities for a) deconstructive learning; b) solving the dilemmas of co-fused aspects of self, and (c) turning state capacities toward self-understanding – can all be forgone (and problems mentioned above, such as grandiosity, hyper-abstraction, and projection are more likely).

These concerns exist in "spiritual growth" contexts, but are also valid throughout the developmental spectrum. For example: "when is it too early to teach a child to read; or give them extended access to a computer?"

In the condensed overview there is much left unsaid, e.g. How such a sequence reiterates through the specific STAGES levels, and how this iteration relates to the specific "emptinesses" of thinking, self, time, duality, and particularity, is suggested in O'Fallon (2020). We leave for another time further discussions of how this relates to: experiences of emptiness vs. fullness; how the sequence involves the dimensions of interior/exterior, self/other, individual/collective, and receptive/active/reciprocal/interpenatrative; how the sequence touches on the primordial modalities of seeing, hearing, and feeling; and where movements of integration fit in with the narrative above that describes moments of differentiation.

4. Conclusions

The Mahayana tradition evolved these practices motivated by compassionate necessity to train heroic adept leaders with the capacity to address the suffering of individuals and culture. The training in ethics, meditation and wisdom was never for the purpose of developing higher states of consciousness or development outside of the cultural necessity for those skills to serve the wider social field. Those who held the lineages of meditation often kept them alive in isolated mountain ashrams. However, this was to keep alive lineages so that when society was ready for them the technologies would be operational.

The task ahead is to create pedagogical environments that lead to the flourishing of a contemplative psychology on western ground. Such integral environments would integrate the practices of psychological healing, self-development, and self-transcendence with the training of the aspirant within a particular field of activity such as law, government, religion or education. Perhaps then we have the hope to become a *civilization beyond discontent* (Brown, 1986).

The purpose of this study has been to assist in the translation of Indo-Tibetan essence psychology into a form that Western psychologists, and educated lay-people can understand. It is hoped that through greater understanding as culture we will come to have a deep appreciate and respect for the profound and insightful psychological theory and praxis that this tradition has to offer and as such be willing to engage in practices seriously for the betterment of the larger social good. At a time when those with the greatest ability to wield power, i.e. the politicians who hold the highest government offices, and billionaires sitting on corporate boards exerting great influence on society, act like sociopaths, there is a dire need for a spiritual and ethical renaissance. Contemplative psychology when enacted correctly can provide that resource.

This paper has outlined the basics of Indo-Tibetan contemplative psychology, the essence psychology of mahamudra and rdzogchen, the stages of adult ego development, and the research on metacognition as means of integrating these different perspective on psychological development with the intention of placing contemplative psychology where it belongs, at the very heart of the psychological understanding of what it means to be a human being.

From the perspective of adult ego development, Indo-Tibetan essence psychology is a body of theoretical knowledge and metacognitive skills that when applied sequentially in the direct experience of the practitioner leads to the unfolding of deeper levels of identity. These levels of identity result from the purification of awareness through disidentification from the deep structures of human consciousness through the three fundamental states of waking, dreaming, and deep sleep. The fundamental praxis is the development of post-formal metacognitive skills. Through the development of attentional self-regulatory metacognition (steering the attention, increasing interest and brightening awareness), the recognition of the impermanent and constructed experience of soma and self, the illusory nature of temporal experience dualistic perception, the individual the practitioner refines his or her metacognition capacity until even the attentional system is seen as an expression of primordial awareness reveals itself.

Currently the practice of this developmental psychology is maintained within the relatively strict boundaries of traditional Tibetan lineages, which, from an exoteric perspective, package the practices in the garb of traditional religion. However, the esoteric theory and practice of Indo-Tibetan Buddhism has little in common with religion and has much to offer the modern world's understanding of mental health. Western psychology is, comparatively, in its infancy, and the advent of positive psychology as a major field is less than two decades old. The field of Indo-Tibetan contemplative psychology offers a tradition of practice developed to mature human positivity to its fullest, and is based on hundreds, even thousands of years of practice-based evidence, which is slowly being corroborated by research in the brain sciences. The integration of mindfulness and compassion practices in psychotherapy is only the very beginning of a meeting of western and eastern psychological traditions. The implications of the meeting could in time lead to a fundamental paradigm shift in psychology and education.

Appendices

Appendix 1: Developmental Stage Descriptions

Below we give a short description of each developmental stage. Descriptions of stages 1.0 to 4.5 combine descriptions from Loevinger, Cook-Greuter, and O'Fallon, while descriptions of Stages 5.0 to 6.5 are from O'Fallon (2010, 2011, 2012, 2013). We primarily make use of the stage names from O'Fallon's STAGES model, which is described in the section "The STAGES model."

Figure A1. STAGES Model (I/C=Individual/Collective; A/P=Active/Passive; Ext/Int=Exterior/Interior) Black numbers (2.0, 5.5, 6.5) show added vs. Cook-Greuter's model.

0.0 to 0.5 (Pre-personal and pre-language Stages). Though they are referred to in some of the cognitively-oriented Structuralist developmental theories, the early pre-personal and pre-language stages of childhood development are not explicated by the constructive developmental theories (though they are referred to in terms of prior building blocks of cognition). This is mainly because these theories of "meaning making" (and ego) development refer primarily to how people understand, describe, and reflect on their understanding – which occurs verbally. These early levels include stages called: sensorimotor (undifferentiated with no real sense of self; 0-6months), and emotional-relational (still not yet differentiated from emotions and is unable to tell the difference between the emotions of self and others; 6 to 24 months).

The majority of adults will pass through the initial stages of pre-personal development although there are those adults with arrested levels due to profound developmental issues such as severe autism, mental retardation, and social neglect who will remain at those early levels.

1.0/Impulsive (concrete-individual-receptive; also "Magical"; onset 2-4 years of age; <5% of adult population).[7] The self is very elementary in functioning, and is operating from a first-person perspective. Piagetian pre-operational thinking is applied to the self and the central development is the ability to use imaginal and word symbols cognitively to represent objects in the inner and outer world. The birth of the symbolic self marks emergence of mental self. However, this mental self is not fully differentiated from emotional or physical world. This leads to magical thinking, wherein a child believes that thoughts and feelings directly interact with the world, and assumes intimate causal and undifferentiated connection between mental, emotional, and physical worlds. Due to this lack of differentiation with the world there is a strong unconscious focus on separation between self and the world with the use of the words “no”, “me,” and “mine” being common.

The self is still fused with impulses and others are only seen as source of gratification. At this level the self can struggle with the lack of capacity for suppression and exhibit acting out behaviors due to the inability to delay gratification and take responsibility for actions. At this point of development the self is also beginning to have the capacity to actively submerge uncomfortable semantic meanings, experiences, emotions and somatic sensations that can lead to psychoneurosis.

1.5/Opportunistic (concrete-individual-active; also "Self Protective"; onset age: older children; 5% adult population). Here the self makes use of a combination of preoperational and early concrete operations to reflect upon itself in such a way that it develops a simple concrete conception of itself. At this level the self still lacks insight into itself however it has gained control over the driving impulses from the prior level of development and as such now has the ability to control itself and is often on guard to control external situations. The Impulsive has the concrete cognitive understanding necessary to know that society has rules that it needs to follow. However, the morality of this self-system is expedience: the self is only bad if caught, and even then is unlikely to express regret or remorse, just anger

The motivation of the Impulsive self is towards its self-serving needs and desires, whether legal or criminal. The self-system is opportunistic and to that end develops a persona to manipulate others and protect its fragile sense of self. It is no longer impulsive yet doesn’t yet understand causality, and therefore lacks planning and an ability to just act with considerable courage. In relationship to others empathy is not well developed in persons at this level of development, so interactions tend to be based on the desires for control, competing for goods, space, power, and the need for self-respect. Feelings are externalized, friendships blow up easily, yet others are to blame and anger is directed against world.

2.0/2.5 (concrete-collective-active and -passive; also "Mythic-Conformist"; onset age: older children, early adolescents, 10% adult population). For convenience we here combine two of the STAGES "second person perspective" levels, following the Loevinger model. This is the first personal stage in that the self is using mature concrete-operations to reflect upon itself and is better able to identify with social norms and images than libidinal drives. In having differentiated from its own drives the self-system now has the opportunity to really connect for the first time to others and to sense belonging to a group, which is strengthened by following the rules and roles of the community. As a member of a group rules now become important as significant psychic structures of identity and are understood as being a priori self-existent or mythically preordained. Having aligned the self with the membership of a group, a simplistic second person perspective – "either you are in or out" – now dominates."

---

[7] Approximate ages of the levels are from Cook-Greuter (2007).

The self-system does its best to look, act, appear, and talk "right" to maintain membership with the group and thus reject those appearances and behavior not of the group. At this stage the self gains acceptance through following the rules and takes comfort in the sameness of others, easily internalizing norms without question and not wanting to stand out from the group. The self-sense has several basic internal states and those that are negative and do not align with the group are repressed and avoided.

3.0/Expert (subtle-individual-receptive; also "Conventional-Interpersonal" or "self-aware"; onset age: older adolescents, young and older adults, 37% adult population). At this stage the self reflects upon itself using a mixture of mature concrete cognition and early formal abstract operations. At this stage, finally, the self is able to take itself as an object, and take a third person perspective on its own experience. Capable of introspection and self-understanding persons at this stage are able to recognize in themselves ways that they stand out from the group. As such, the ability to see themselves adds more complex nuance to their self-reflection and there is an appreciation of their uniqueness. At *Expert* the sense of uniqueness allows the self to stand apart from the group, bringing a sense of self-consciousness and sometimes also a preoccupation with how others will judge one's differences. These new capacities lead to the ability to appreciate difference in others, and this leads to an increased level of complexity in relationships. This is the first stage where people describe relationships in terms of the inner world of feeling and emotion.

Kegan (1995) describes how this stage fulfills the developmental expectations for adults in traditional pre-modern societies. A person now has a capacity for foresight, the ability to adjust to changing circumstances, and understand notions of adult accountability and responsibility. However, the *Expert* self-system has not yet caught up to the level of self-determination needed to navigate modern society and struggles with finding integrity between self and the membership group.

3.5/Achiever (subtle-individual-active; also "Rational-Self Authoring" or "Conscientious"; onset age: older adolescents, young and older adults; 30% adult population). This is the target level for our culture at the present time. At this level of development, the self-system is able to reflect upon itself using formal operational cognition. Rational-Self Authoring self-systems add linear time to their rational thought processes thinking forward and backward in time and expanding their social context to include those outside their ethno-national membership group to include others across time and culture who share their ideals and aspirations. They are willing and able to work for the betterment of all. The ability to reason, to have metacognitive thinking about thinking, and reflect upon the conditioning symbols, scripts, norms and conventions of prior levels leads to a more introspective ego, and a concern with the cultivation of a stronger clear sense of individuality free from external authority. Living life by one's own internal authority and chosen standards can cause guilt if not lived up to. At this stage there is a belief in the objective scientific method, in rationality, as well as in empiricism and positivism to uncover the truth about the world. This is accompanied by belief in the perfectibility of mankind.

4.0/Pluralist (subtle-collective-reciprocal; also "Relativistic-Sensitive"; 10% adult population). This cognitive level has been the leading edge of Western culture for the last 40 years and is developed by the integration of mature formal operational and systemic thinking within the self-system. This is the beginning of general systems thinking described by Koplowitz (1984) with variables that are interdependent, causality this that cyclical, and boundaries between objects that are open and flexible. This 4th person perspectival capacity is characterized by the ability to be aware of the contexts within which the contents of experience arise. This ability leads to a greater interest in self-understanding and deep questioning. The self may be experienced as a multiplicity of voices such as described in the Internal Family Systems model (Schwartz, 1997).

Here it is understood that subject/object distinctiveness is not absolute, and the idea of the participant-observer is understood as the subject/object boundary become permeable. Whilst this stage maintains a capacity for awareness of past and future, the *Pluralist* self -system is more interested in the present moment fed by interest in such things as eastern wisdom traditions, self-help books, and therapies emphasizing the present moment. There is a heightened differentiation of self from the group membership and a willingness to pursue personal counterculture life goals if need be. The ability to see the relativity of truth leads to a deep pluralistic sensitivity towards those perspectives marginalized by mainstream society, with a greater recognition and celebration of individual and cultural diversity.

4.5/Strategist (subtle-collective-interpenetrative; also "Integrated-Multiperspectival"; 5% adult population). This is the level of development that Kegan (1994) calls the "honors track" of the cultural curriculum, and the level that Wilber increasingly emphasized in his writing on Integral Theory. The self-system at this level has metasystemic cognitive capacity (cognitive stage 6) and is able to apply those cognitions onto the self-system. Whilst Pluralist self-systems can struggle with the cacophony of self-parts, the Strategist self-system is able to integrate the self into a whole system integrating mind and body, reason and emotion, intuition and rationality. Preoccupation orientates towards personal development and the actualization of potential. Distressing emotions are more tolerated and paradoxical elements can be integrated into a system of logic. This frees up more energy, as the self is no longer defending itself against disavowed psychological material.

At Strategist one's life work is motivated by becoming all one can be, and, for persons in this stage, wanting to help others grow is one of their strongest motivations. Strategist self-systems are attracted to work as psychologists, coaches, consultant, and executive leadership positions. Integrated-multiperspectival selves can see life as an open-ended journey with no predetermined end, giving the full responsibility to each individual for his or her fulfillment.

5.0/Construct-Aware (Metaware, Individual, Passive, Receptive; 1% adult population). As the self moves into the metaware tier the person develops the capacity to discern the nuances of awareness itself. At the initial recognition of the 5.0 the direction of the attention is external and the witnessing ego arises with more focus on the objects arising in awareness. These individuals have the capacity to take perspective on perspectives so much so that they begin to see what is tantamount to a hall of mirrors. They are able to take perspectives on perspectives at will. Some experience this as a capacity to envision multiple meaning loops; others become aware of their feelings looping (feeling a feeling about a feeling, or feeling a feeling). With a witnessing awareness activated the person becomes aware of projections arising in the moment. The subtle ego is recognized and conceptions that were once concrete are now recognized as constructs generated by the subtle mind and are experienced as empty and impermanent. This gives rises to the experience of groundlessness; that there is no concreteness in reality is a realization that can bring about an acute existential angst in some.

The cognitive capacity to be aware in the moment of multiple generations of stories and constructions arises, and with it the ability to experience the self, as a multi-generational impermanent process. Awareness of space increases to include the larger Cosmos. As the 5.0 individual matures his or her perspective shifts from external cognition to internal and the focus is more on awareness of awareness itself, which brings a lucid emptiness to every object that arises within it. In the awe of such a larger vision a concern about hubris and spiritual arrogance needs to be transformed by a genuine humility.

Behavioral cues of 5.0 include a difficulty in speaking coherently due to the constant witnessing of the observing awareness over the perceived limited communicative capacity of the self-system. Since there are not many individuals operating at this level of development they can feel isolated and question their own sanity.

As development proceeds at this stage, emptiness and silence of awareness moves towards undergirding the entirety of ordinary experience as individuals at this level of meta-cognitive development begin to settle into their new identity as awareness, the witnessing awareness of full and empty, concrete and subtle objects.

5.5/Transpersonal (Metaware, Individual, Active, Active; <0.5% adult population). As the capacity for witnessing awareness developed at 5.0 becomes familiar, constant, and ordinary, with awareness of awareness being brought into complex interactions and understandings of the world, the self-system discovers a greater sense of freedom. There is a continued development of one's own awareness of awareness of objects but this capacity is still polarized with awareness of the objects themselves. So that the 5.5 system may switch into a mode of immanent integration of body and mind, heart and head, inner and outer, or conversely operate from a decentered transpersonal perspective of an observing ego. However, they are not yet able to carry out both operations simultaneously.

At 5.5 the self-system begins to recognize that certain conceptual constructs and narratives are more useful that others depending on the circumstances and the effect these operations have on others and the specific situations involved. In activity individuals at this level have the capacity and mental pliancy to synthesize multiple perspectives. These conceptions themselves might not be unique, but the complexity is multi-dimensional which often leaves 5.5 feeling unseen, misunderstood, and often lonely.

Often persons with a 5.5 self-system do not take feedback well if they sense that the other does not understanding the complexity that they are basing their perceptions on. The 5.5 can be recognized by their fluent complex, vivid, and playful language style displaying a remarkable and yet ephemeral intelligence. They have a capacity to hold virtually anyone with a depth of compassion and concern, and an ability to speak often with a “stream of consciousness” quality. They can come across as arrogant in that they are sure of their choices, often willing to yield and yet surprisingly rigid in their personal perspective. At 5.5 the self-system is able to recognize the metaware capacities of others, but not yet cognizant that others might also be able to perceive their metacognitive capacities in return.

6.0/Universal (Metaware, Collective, Passive, Reciprocal; <0.05% adult population). At the Universal 6.0 stage the metaware collective is in the foreground of experience. This collective contains the entire manifestation of concrete, subtle, and metaware objects. The 6.0 self-system exhibits the ability to let go of the 5.5 complexities even whilst functioning within it, and has the capacity to integrate both poles of immanence and transcendence, form and emptiness into an integrated both/and perspective, able to recognize the recognition of awareness whilst involved in day-to-day activities. Their mode of operation has a deep acceptance of life without the compulsive need to change self or others.

At this stage a new sense of the collective arises, a sense of the formless ‘we’ arising within the field of awareness. This is a non-hierarchal stage where everything arises together simultaneously within awareness. The experience of time and space becomes infinite, with occasional spontaneous eruptions of “all at once” knowingness, non-duality without a center of psychological operations, and without casual operations of knowing. There is a general experience of universal interconnection and inter-being integrated into the everydayness of life. What may have once been a state experience of universality has become an ordinary experience of operation and there arises a direct understanding of the evolutionary process of the Whole. With the experience of “everything perfect as it is” the 6.0 self-system no longer has the pressured complexity often common at 5.5 and language can become more poetic, unique and vivid to communicate the paradox of simultaneous time/timelessness and specificity/infinity.

6.5/Illumined (Metaware, Collective, Active, Interpenetrative). In the polarity of active/passive development the Illumined stage is the active fruition of the metaware tier as such there is a greater degree of integrating active functioning into the non-duality of immanent form and empty transcendence. Non-dual states continue to increase as the inherent natural dynamism of growth continues with the projection of one’s metaware interior knowingness and exterior unboundedness into the world and the introjection of the world into oneself, the precursor of the non-dual tier.

In turn, recognition of deep patterns akin to those experienced at the 5.5 stage reappear. The self-system looks forward and backward throughout all developmental history and across the various fields of knowledge in consciousness, science, culture, and social systems within the larger expanse of all space and time. The Illumined is able to spontaneously recognize the deep patterning of humanity. The patterns differ from those at 5.5 in that whilst simple they are holographic and simultaneously include the whole. Illuminatives are likely to experience this process as a flow of information that comes through them, that they are simple transducers of information.

Unitive/Non-dual Tier: 7.0, 7.5, 8.0, 8.5. O'Fallon notes that all the stages through 6.5 operate under the function of the categorizing, distinction making, and perspective taking mind. A signal of moving into a hypothesized 4th Non-dual tier is the recognition of this perspective-making mind by a centerless nondual awareness (O'Fallon, 2013).

Appendix 2: Metacognition

Fundamentals of Metacognition

Metacognitive Theories. Simply put, metacognition is *cognition about cognition* (Flavell 1979). This has often been simplified in the literature as 'thinking about thinking," however, metacognition does not have to rely upon thought, and can be non-conceptual in the form of *metacognitive insight* (Teasdale et al., 2002). As such, the word *cognition*, "the mental action or process of acquiring knowledge and understanding through thought, experience, and the senses" (Oxford, 2007), is more appropriate than the word *thought.* This is particularly important in the more advanced forms of metacognition that rely upon metacognitive awareness and not just metacognitive thinking. For instance, the metacognitive tracking of one's basis of operation, the psychological location of identity, is non-conceptual and does not involve the use of thought, but rather maintaining an awareness of how information is being processed.

Writings on metacognition in Western civilization date as far back as the De Anima and Parva Naturalia by the Greek philosopher Aristotle (Colman, 2015). In America, metacognition or *introspection* as it was known, was first popularized in the writings of William James (1890) as his fundamental method of psychological inquiry. Tarricone (2011) identifies the main theorists in the modern field of metacognition theory as Flavell, Brown, Borkowski and Pressley, and Kuhn. Flavell (1977) explored the role of reflection in *self-regulation* for (individual) *learning* and *problem solving* (Brown, 1987). Flavell's model has three fundamental components, metacognitive knowledge (including meta-memory), metacognitive experience (in-the-moment processing), and metacognitive skills (for the evaluation and regulation of cognitive processing). *Critical thinking* involves asking good questions and considering alternative possibilities which, according to Richard Paul (Paul & Elder, 2008), requires metacognition to effectively mobilize the elements of thought (purposiveness, perspective taking, outcome analysis, bias bracketing, interpretation, and information gathering), and to monitor the standards of thought (clarity, accuracy, relevance, precision, significance, completeness, fairness, and depth) (Paul & Elder, 2008).

Much of the work in metacognition has focused on self-*understanding* and self-*regulation*. Brown's (1975) model includes knowing (comprehension), knowing how to know (inquiring and learning strategies), and knowing about knowing (*metacomprehension*). Kuhn's (2000) metacognitive theory of metaknowing adds, among other things, a clearer differentiation between declarative (know-that) and procedural (know-how) aspects of metacognition.

Brown (2006) takes a quasi-developmental approach to divide metacognitive skills into basic, intermediate, and advanced – in a system that anticipates the more advanced forms applied in the contemplative essence practices. The *basic* skills include the development of awareness of mind of self or other, monitoring the accuracy of state of mind, awareness of one's influence on the other's state or behavior (and vice versa), becoming aware of one's state of mind in such a way that it has a regulatory effect on the state, awareness of one's own or another's action plans and goal directedness, and meaning making. The *intermediate* metacognitive skills to be developed include the recognition of how the past and the projection of the future shapes one's experience, appreciating the relativity of states of mind, seeing into the underlying assumptions and expectancies related to information, optimizing action plans in the face of accurate awareness of limitations, fostering sensitivity to contextual effects on behavior, and perspective taking, the ability to consider something from another's point of view. The *advanced* metacognitive skills include taking a wider, super systemic perspective, developing metacognitive awareness of past/present, self/other or child/adult orientations, awareness of the degree of organization or coherence of one's mind, recognition of interdependence, articulation of ultimate concerns, the direct, non-representational awareness of a wider reality, and refined meditative metacognitive skills.

Borkowski and Pressley's (2000) model adds, among other things, the importance of self-efficacy, self-esteem, and motivation in meta-cognitive processes – emphasizing the interplay of *emotional* with cognitive processing. According to Lai (2001), several researchers have emphasized how motivation is an integral component of metacognitive experience, providing the capacity for the enjoyment of learning, curiosity, persistence in the face of challenge, and management of affective states (Cross & Paris, 1988; Martinez, 2006; Paris & Winograd (1990)).[8] Below we also discuss CBT therapy, which emphasizes *acceptance* of the contents of the mind.

The Soviet psychologist, Lev Vygotsky (1978) explained the importance of explicit verbalization during *social* cognitive interaction. Hearing others reflect about us, or about themselves, becomes internalized as an inner dialogue about ourselves, which is a foundation for metacognitive reflection. This intersubjective (intrapsychic) component of metacognition is a key factor in attachment theory and various approaches to psychopathology. Below we explore this more under "Attachment Therapy."

Aspects of metacognition. These are at least few hundreds of researchers and theoreticians who have considered metacognition. Historically, "metacognition is not only a monster of obscure parentage, but a many-headed monster at that" (Brown, 1987, p. 105). Yet we will attempt to sketch the overall contours of this convolutedly textured field as follows. Early work in metacognition differentiated primary (first order) from second order cognition, where primary cognition refers to the *contents* of thought, feeling, or perception. Second order cognition is often described as thinking about thinking, but it can also include: thinking about feeling, thinking about perception; and *sensing into* (i.e. feeling/perceiving) the experiential nature of one's thinking, feeling, or perception. An additional complication is that this second order "thinking" can relate to its subject (content) in many ways, including: assessing its features and contours, evaluating its quality or value according to some standard or goal, manipulating (directing, subduing, or transforming) it, and anticipating or planning how it will or should manifest in the future. To make matters even more complicated, metacognition might include thinking about one's memory, attention, intentions, skills, beliefs, personality, learning style, or meaning-making (which could include how one understands knowledge and knowing (epistemological belief system), and how one weaves narratives/stories from given information). Different theorists have different terms for many of these sub-types, and many use restrictive meanings for "metacognition" that don't include all of these things.

---

[8] According to Schraw et al. (2006) metacognitive motivation has two subcomponents: self-efficacy and epistemology. Self-efficacy relates to the confidence level a learner brings to accomplish a specific task or goal, and epistemological beliefs relate to the beliefs a learner has about the origin, nature, and epistemological paradigm of knowledge (absolutist, scientific, relativistic, etc.).

There are a number of domains of psychological and cognitive research in which metacognition is fundamental, where again, the relationships between terms becomes quite fuzzy or diverse. These include: cognitive psychology (metamemory, abstraction, memory storage and retrieval), neuropsychology (executive functioning), educational psychology (self-regulated learning, inquiry), developmental psychology (theory of mind, self-awareness, meaning-making), clinical psychology (mentalization, self-understanding, identity), and problem solving (reflective thinking, critical thinking, creativity, "higher order thinking").

Though we will not attempt to create a new order or synthesis out of this tangled set of phenomena (Brown's "monster"), we can offer some distinctions that will simplify things enough to allow us to apply the field to contemplative practice.

First, we can differentiate meta-knowledge (knowing about knowing) into things one knows about *oneself* vs. more general principles that one believes apply to human thinking and knowing in general. In this study of contemplative psychology we focus on the former, on insight gained through self-observation (though of course more general knowledge obtains through both meditation instruction and in how one infers that others' minds work like ones' own mind).

Second, some operations build upon others by definition, adding a bit of structure to the quagmire. For example, one must be able to observe something (awareness) before one can monitor it or reflect upon it verbally; and one must be able to monitor/reflect upon something in order to engage in more sophisticated tasks such as predicting, controlling, or transforming it. This begins to add the developmental lens.

Third, we can observe that some of the confusion or theoretical diversity in this field is due to the limiting nature of the concept "meta" (as in metacognition, metamemory, etc.). That fact is, the metacognition that operates upon some content can become the *content* for a higher level of metacognition. For example, many would say that "problem solving" or "critical thinking" require metacognition, and thus thinking about one's problem solving or critical thinking would be meta-meta-cognition. We can see that terms meta-meta, meta-meta-meta, etc. quickly become untenable and confusing designators.

Modern developmental theories allow for greater precision in this regard. The 12-16 levels defined by theories of hierarchical complexity begin with the lowest levels of sensorimotor processing (some start even lower at logical operations executed at the information processing level of neurons – see Commons & Richards,1984). Each level "operates upon" the prior level, where "operating upon" is a "meta" move that can take any form – e.g. to observe or monitor, to assess, to compare or differentiate, to coordinate or synthesize, to manipulate or control, etc. (IBID; Fisher 1980). Advanced levels of metacognition, such as the monitoring of the psychological basis of operation, or the metacognitive insight into the constructed nature of sensory and psychological information, can be considered post-formal (dialectical third order) cognitive operations, where different perspectives on metacognition itself can be taken.[9]

Therefor we will usually use "metacognition" to refer to thought or perception that operates upon *some content*, to differentiate the content from the meta-content in that context (even though in another context the meta-level might become the content level). When we need to be more precise we will often refer to specific developmental levels. We will also try to be clear in each context what type of "meta-move" or operation we are referring to. For example, ego development is largely driven by the "subject to object" meta-move, in which some invisible aspect of the unconscious mind that influences thought or behavior (i.e. we are subject to it) becomes seen, so that we can reflect upon it (as object). Establishing a "view" is yet another type of move, as we will discuss.

Meta-knowing, meta-sensing, and meta-thinking. Finally (fourth), and critically for our treatment, we can combine Brown's and Flavell's models to differentiate *meta-knowing, meta-sensing, and meta-thinking*. All three forms of metacognition can operate upon *any* of the types of content mentioned (feelings, memory, thinking, etc.). Meta-knowing (including meta-comprehension, meta-memory, and meta-skills) refers to *stored* knowledge about how cognition works, and stored strategies used to guide any of the metacognitive processes (e.g. procedures specifying what/when/how/why to apply, or improve each metacognitive sub-process). Meta-knowing includes procedural skills designed to monitor cognitive progress through the use of strategic metacognitive regulation, or executive control (Brown, 1987). These skills include knowledge about orientation, planning, regulation, monitoring, and evaluation strategies used to control cognitive activity in order to achieve a cognitive goal. Metacognitive skills allow a learner to oversee a learning or problems solving process in reference to internal or external standards.

Meta-thinking and meta-sensing are both *in-the moment* processes (vs. meta-knowledge, which is information or procedural skill retrieved from memory). Meta-thinking involves reflective (explicit conceptual) thought (including evaluation and strategizing). Meta-sensing is non-conceptual, perceptual, and experiential. One can access (recall) stored meta-knowledge (i.e. information or procedures) like a "program" in memory, and then "execute" this procedure, i.e. actual *do* what it specifies, to then have an in-the-moment experience of meta-thinking or meta-sensing. Though meta-thinking is the primary focus of metacognitive scholarship, including its use in critical thinking, problem solving, and self-directed learning, meta-*sensing* is as, or more, important in contemplative psychology.

Meta-sensing (or "metacognitive experience") consists of direct conscious cognitive and affective *states* involving awareness, thoughts, intuitions, perceptions, feelings, and judgments appreciative or responsive to in-the-moment experience (Tarricone, 2011). Meta-sensing is perceptual, non-conceptual, and non-reflective, and is constituted by the felt-sense of being in any moment and context. "Felt sense" is a term used to hold both the perceptual aspect (as in Davie Bohm's (1980) "proprioceptive thought") and the feeling (affective) aspect. Such feelings include the feeling of knowing something, feeling of familiarity, feeling of confidence, feeling of difficulty, feeling of knowledge saturation, feeling of boredom, and feeling of satisfaction.[10] Meta-sensing provides the internal feedback mechanism about the current progress, degree of comprehension, and future expectation of success or failure associated with a given task, and thus usually are framed in terms of the goals, constraints, demands, and challenges of a task (Efklides, 2008, p. 279; Tarricone, 2011). Yet, while it provides information for meta-thinking (and meta-knowing), meta-sensing *in itself* involves a more open and peripheral awareness *without* specific goals (– it often operates in a context that includes parallel processes that set and monitor goals).

---

[9] This relates to Jankowski and Holas's model of mindfulness (2014), which proposes that there might be the possibility of numerous metacognitive levels, with each level being both a meta-level for the previous and an object level for the next one.

Meta-sensing is similar to the Awareness of Transient Information (ATI) component of Grossenbacher and Quaglia's (2017) model of Contemplative Cognition. ATI refers to the basic cognitive process of being aware of the *transient objects* of experience such as sensory information, affect, memory, imagery, and thought. ATI is the central feature of those meditations designed to cultivate moment-by-moment choiceless awareness of the ongoing stream of consciousness such as the choiceless awareness of Zen shikantaza (just sitting) meditation. We will return to meta-sensing in our discussion of View in mahamudra practice.

Metacognition and Psychotherapy

Clinical psychology, in particular psychotherapy, is an activity that includes making revisions to interpretations of experience, and has been conceptualized by some as a form of *learning* (Bandura, 1961, Mahoney, 1977, Rose, Loewenthal, & Greenwood, 2005). Metacognition is a central aspect of learning, "the process of making a new or revised interpretation of the meaning of an experience which guides subsequent understanding, appreciation and action" (Mezirow, 1990, p. 1). The understanding of psychotherapy as an educational process goes all the way back to Sigmund Freud, the pioneer of the psychodynamic approach to psychoanalytic treatment, which he justly described as a kind of "after-education" (Freud, 1977, p. 504). Carl Rogers (1969), a pioneer of the humanistic approach to psychology, likewise described psychotherapy as a form of "*significant learning*" (Rogers, 1959, p. 280).

Metacognition is critical to many psychoanalytic processes, including the analysis of the transference projection, the monitoring of emotional activity in emotion-focused therapy, and the differentiation and recognition of the voices of internal systemic parts in internal family systems therapy. Below we will describe more specifically how it applies to two contemporary models, Cognitive Behavioral Therapy (and its derivatives: CBT, MBCT, and ACT) and Attachment Therapy.

CBT, MBCT, and ACT. Cognitive behavioral therapy (CBT) is defined by Hofmann, Asmundson and Beck (2013) as a family of interventions founded on rational emotive behavior therapy, cognitive therapy, stress inoculation therapy, problem-solving therapy, schema therapy, and acceptance and commitment therapy (Dobson, 2010). Meta-analyses of the efficacy of CBT have shown large effect sizes for unipolar depression, generalized anxiety disorder, panic disorder with or without agoraphobia, social phobia, posttraumatic stress disorder, and childhood depressive and anxiety disorders (Butler, Chapman, Forman, & Beck, 2006).

---

[10] The evidence that there is an affective nature of metacognitive experiences has been supported by neuropsychological research showing the location of metacognitive monitoring in the anterior cingulate cortex (Fernandez-Duque et al., 2000). The anterior cingulate cortex is connected to both affective and cognitive regulatory loops. Two affective loops have been suggested involving this cortex. The first detects the discrepancy from the goal set and generates negate affect in response to discrepancy, and the second monitors the rate of discrepancy reduction as one progresses towards the goal and can generate both negative and positive affect in response to the progress towards task completion (Efklides, 2006).

While it is true that metacognitive strategies have always been a part of CBT (Wells, & Purdon, 1999), metacognitive awareness in these forms of therapy is generally in the service of *changing* the contents of the dysfunctional cognitive behavioral patterns into more adaptive patterns (Dobson, 2013). In recent years there has been the development of a "third wave" in CBT, with an explicit shift to more advanced metacognitive or contextual approaches to treatment (Hayes, Villatte, & Hildebrandt, 2011). These approaches focus on the recognition and *acceptance* of the content of the mind (beliefs, thoughts, emotions, and sensations) rather than changing them. Acceptance has been implicitly a central feature of many psychotherapeutic approaches, for example Freud's psychoanalysis, Rogerian client-centered treatment (Rogers, 1995), and Gendlin's focusing (Gendlin, 2012). Third wave CBT approaches, such as mindfulness based cognitive therapy (MBCT), and acceptance and commitment therapy (ACT), have, however, made explicit the psychological *acceptance* of experience as a central mechanism of therapeutic transformation.

MBCT is defined as an intervention primarily designed to increase metacognitive awareness by changing the patient's relationship to negative thoughts and feelings without any direct conscious attempt to change belief in the content of negative thoughts or underlying assumptions (though change in assumptions or thought patterns are often an indirect outcome) (Teasdale, et al., 2002). Teasdale emphasizes that it is the metacognitive *awareness* into the unfolding mental content in the direct experience of the *present moment* (what we termed meta-sensing) and not conceptual metacognitive knowledge (meta-knowing and meta-thinking) that is the therapeutic agent of change, and that it is a deficit of a specific kind of metacognitive monitoring into that leads to depression (Teasdale, 1999). Similarly, ACT focuses on changing the client's relationships to thought through *cognitive defusion*, "the creation of nonliteral, non-evaluative contexts that diminish the unnecessary regulatory function of cognitive events" (Hayes, et al., 2013 p.4). ACT and MBCT teach the client to come into direct experiential contact with the present moment (rather than being dominated by conceptualizations of the past and future) and, rather than attempting to alter the form, frequency, or intensity of cognitive experience (experiential avoidance), learn to accept it and be curious about it (Hayes et al., 1996).

ACT goes further than MBCT in articulating that through the repetition of metacognitive disembedding from cognitive fusion and accepting the present moment, there is a shift in psychological operation from *self as content* (i.e. from fusion with a conceptualized narrative of self) to *self as context*, in which one operates psychologically as the observing self (Deikman, 1982), and comes to notice a transcendent sense of self (Hayes et al., 2013). The ACT process of metacognitive defusion parallels concepts in psychological literature referred to as reperceiving (Shapiro & Carlson, 2009), decentering (Safran & Segal, 1990), deautomatization (Deikman, 1982), and detachment (Bohart, 1983). Such processes support a shift in perspective that leads to an experience of self beyond conceptual construction. This shift in operation happens by making the prior subject of experience (the narrative-content self) an object. It is this process of making *the subject the object* (Kegan, 1982). However, western therapies such as ACT do not have the means to make self-as-context a stable trait. This is the goal of Buddhist contemplative psychology (discussed later).

Attachment Therapy. The physical and psychological attachment of the child to its caregiver is fundamental to the development and stabilization of the capacity for self-regulation, self-recognition, self-monitoring, and the development of a theory of mind (i.e. an understanding of people's minds work). Without first learning about internal regulation by being (externally) regulated by the loving presence of a mother or caregiver it is difficult for a person to develop affect regulation, an unfortunate result such as is seen in borderline character injury (Fonagy et al., 2000). Without first learning about the self through having care-givers direct their interest to realizing the uniqueness of the child, it is difficult for the self to develop capacity for self-reflection, such as is seen in narcissistic character injury (Bennett, 2006). Psychological attachment is fundamental to the development and functioning of a healthy self-structure.

In *Attachment Disturbances in adults*, Brown (2016) surveys the history of this field. John Flavell's (1979) appearance-reality distinction was an early influence. Following Flavell, Mary Main included a "Metacognitive Monitoring scale" in her adult Attachment Interview, which she used in research that discovered that those children with insecure attachment were more cognitively fused with their thoughts, beliefs, and mental models of reality, were less able to take them as mental representations, and were thus prone to distortion (Main, 1991).

Semerari, Dimaggio, and Liotti and their associates developed a highly refined modular perspective on metacognition. By separating it into six independent sub-functions (identification, relating variables, differentiation, integration de-centration, and mastery) they were able to differentiate specific deficiencies in borderline, narcissistic, and dissociative disorders (Semerari et al., 2003). Their Metacognitive Assessment Scale (MAS) allows the therapist to identify and work on developing a patient’s specific deficient metacognitive sub-function. Brown and associates' psychotherapeutic model (2016) integrate several prior schools of thought and adds a more advanced set of post-formal metacognitive skills, as explained above (in his division of metacognitive skills into basic, intermediate, and advanced).

In sum, metacognition is the central feature of the psychological therapeutic process in many schools. In the disembedding from identification with dysfunctional experience such as maladaptive thoughts, negative beliefs, reactive emotions, and traumatic sensations, the client is able to develop perspective on their experience that allows for transformation.

Metacognition and Meditation

The construct of metacognition (in its various forms) has been used by a number of theorists to explain the mechanisms of contemplative practice. These treatments of metacognition have a very different flavor vs. theories developed in the traditional context of problem solving, self-mastery, and self-regulated learning. There is more overlap between contemplative and *psychotherapeutic* treatments of metacognition. This is in part because contemplative practices (and psychotherapy) are largely about deconstructive or *disembedding* processes that free the self from prior conditioning to open up new fields of awareness and freedom, while problem solving etc. are more concerned with *building up* capacities to achieve goals. The sub-domain of contemplative practice called "mindfulness" actually sits in between these two goals, as it has a skill-building outcome of sharpening focused attention (i.e. concentration) that is a first step in many contemplative models; while focused attention is also an important capacity in many intellectual domains such as problems solving and learning.

Mindfulness. Mindfulness was polarized by Jon Kabat-Zinn (2009) through his mindfulness-based stress reduction framework (MBSR). MBSR was developed to address chronic pain, it has come to play a central role in a number of psychotherapies and self-improvement modalities including mindfulness based cognitive therapy (MBCT), dialectical behavioral therapy (DBT), acceptance and commitment therapy (ACT), and somatic experiencing. Kabat-Zinn (2009, p. 4) defined mindfulness as "paying attention in a particular way: on purpose, in the present moment, and non-judgmentally."[11]

Beyond Mindfulness. As mentioned, in contemplative essence psychology mindfulness is only a preliminary step (along with establishing a foundation in ethics and right motivation/intention). Churchill (2018 – the dissertation upon which this paper is based) surveys a number of cognitive models of contemplative practice in detail, including: Jankowski and Holas' and model of metacognition and mindfulness, which is developmental/hierarchical (2014); Yates' (2017) two-tiered metacognitive model of mindfulness; Grossenbacher and Quaglia's model of Contemplative Cognition (2017); and Dorjee's (2016) contemplative science framework which includes metacognitive self-regulatory capacity (MSRC) and the associated modes of existential awareness (MEA).

These models draw on many of the elements of metacognition (and executive functioning) described above. For example, Dorjee's (2016) model includes the term "metacognitive self-regulatory capacity" of the mind (MSRC), to describe contemplative processes. As one could predict, contemplative practice methods and the attainment of various levels of contemplative capacity involve meta-*knowledge*, meta-*skills*, and meta-*sensing*; and include *affective* elements including motivation, self-confidence, and humility. As described form metacognition in general, contemplative metacognition includes components that sense, monitor, evaluate, and manage/control/regulate various cognitive processes including thought, perception, intention, attention, goals, values, beliefs, habits, and identity (sense of self) etc.

Metacognitive levels. Each of these models suggests stacked hierarchical structures illustrating which processes are meta for (i.e. operate upon) others. As we indicated above, the limitations of the concept of meta means that each theory breaks up the space in a different way. One issue is that certain processes that set the context for meditative practice, such as motivations/intentions/goals, attitudes of acceptance, and meta-knowledge about how the mind works, might be said to be foundational assumptions (bottom-up influence) or control processes (top-down influence) in these quasi-linear models, when in fact most sub-processes operate in tandem in a co-creational system of feedback/feed-forward relationships (this idea is an application of the Buddhist principle of dependent origination; a truth that implies that component-based models of cognitive processes will always be substantial simplifications of the reality).

---

[11] A more refined definition developed by Bishop et. al. (2004) can be summarized as follows: mindfulness is the self-regulation of attention on immediate experience, maintained by sustained attention, attentional switching, and the inhibition of secondary elaborative thought processes, that allows for the increased recognition of mental events characterized by a curious, open and accepting orientation towards present experience, leading to insight into the nature of cognitive experience, the adoption of a decentered perspective on subjectivity, and the transience of sensation, emotion and thought. In short, mindfulness is form of metacognition.

Advanced metacognition. Another thing that distinguishes models of contemplative metacognition from other models of metacognition is that many of the former are interested in *advanced* skills achieved by contemplative adepts with decades of training, as opposed to models used to guide academic learning, problem solving success, or self-improvement for "anybody." Thus they are more likely to include multiple stages or levels, and are more likely to form a bridge to developmental theories (which have many levels).[12]

For example, Yates (2017) notes that following the fundamental practice of attention to breathing etc., as metacognitive decentralized awareness comes online, it can lead to personal insights of phenomena described in Buddhist psychology, including insights into impermanence, no-self, and reactivity (dukkha). The highest (meta-meta) level of Jankowski and Holas' (2014) model includes the meta-awareness of decentration and experiential acceptance. This model differentiates *controlling* vs. *inhibiting* processes, where mid-level metacognition controls perception, thought, emotion, etc., while higher level metacognition inhibits beliefs and thought-habits that impede the process-level goals. According to Jankowski and Holas (2014), the person who achieves this higher level of meditation then starts to become aware of clarity (fundamental awareness), the most fundamental and basic form of reflexive non-conceptual cognition that makes all other types of cognition feasible and forms the central feature of consciousness itself,

Awareness, attention, and intention. Grossenbacher and Quaglia’s model (2017) elaborates on the developmental ratcheting relationship between awareness, attention, and intention. *Awareness*, or "Awareness of transient information" (ATI), refers to the basic cognitive process of being aware of the transient objects of experience such as sensory information, affect, memory, imagery, and thought. ATI is the central feature of those meditations designed to cultivate moment-by-moment choiceless awareness of the ongoing stream of consciousness such as the choiceless awareness of Zen shikantaza (just sitting) meditation. Choiceless awareness, *without* focused attention or specific intention, is difficult to achieve, and many contemplative models *include* modes of intention and attention that deconstruct or disembed layers of cognitive processing that impeded choiceless awareness.

Grossenbacher and Quaglia’s model includes "intended attention" (IA), i.e. processes and practices designed to develop *attentional* stability. One has an intention to focus on a particular type of cognitive phenomena, and eventually achieves stable attention upon it. IA is the central feature of those meditations designed to develop attentional stability such as Indo-Tibetan calm/staying practice. From this concentration something is learned about that object of awareness and its conditioned nature, and one's understanding and processing habits begin to shift toward freedom from that form of conditioning.

---

[12] Note however that developmental theories are theories of learned traits, i.e. skills, and while a skills can build layer upon layer through many levels simply through reflective practice over time (given the right conditions), in-the-moment metacognitive processes may be more limited in the number of layers in simultaneous operation.

From this new basis, new insights may emerge (or previously obscure meditation instructions may become comprehensible) leading to a new *intention* to focus attention on a different object (or different layer of mental processing). Using this "attention to intention" (AI), the meditator monitors, assesses, and adapts the higher-level goals (intentions) of the contemplative process. Grossenbacher and Quaglia define AI as the “attentional modulation and/or monitoring of an intention whether through facilitation of a selected intention, inhibition of competing intentions, sustaining an already operating intention, or reengaging one that has waned” (2017, p. 15). While AI monitors and adapts the processes of intending in the present, IA attends to the more global meta-process of adjusting the AI process itself. The model shows has awareness (ATI), attention (IA), and intention (AI) reciprocally strengthen each other.

As mentioned above, contemplative practice usually involves multiple goals/intentions operating in parallel at different levels. For example, while at the local level one may have an intention of focusing on boldly sensations, at a more general level one may be mediating to cultivated strong altruistic motivation to benefit the field of all interconnected beings, a central feature in the Indo-Tibetan bodhicitta practices.

Grossenbacher and Quaglia (2017) are clearer than other theorists that the practice of meditation is not sufficient to cause the development of this metacognitive contemplative cognition. In order for mature contemplative cognition to develop the practitioner needs to consciously understand, activate, and integrate the functions of ATI, IA and AI beyond the context of formal meditation practice. This perspective is shared by the Buddhist essence traditions of mahamudra and rdzogchen where the informal, pathwalking practice of integrating meditative awareness into everyday living is fundamental to the understanding of the contemplative path.

Views: Modes of Existential Awareness. None of the models described above contains an elaborated explanation of the system of "views" described in mahamudra practice, the levels of the non-conceptual awareness (i.e. meta-sensing, of what arises in the mind moment-by-moment, Grossenbacher and Quaglia's "Awareness of Transient Information"). Dorjee’s model explicitly acknowledges the need to better articulate this progression of views, which they call "modes of existential awareness" (MEA), come from the increasing degrees of de-reification achievable with contemplative practice (what Wilber calls "state stages", 2014). Again, developmental theory can be useful here, because it does not become daunted in trying to articulate multiple iterations of meta-levels, but takes the transcend-and-include process of hierarchical complexity for granted in its articulation of levels.

In summary, metacognition is an important construct and field of study for the investigation into mapping the contemplative essence psychology of Indo-Tibetan Buddhism in terms of mature adult cognitive and ego development. Through the process of complex adult cognition, metacognition facilitates ego development, and, as discussed above, metacognition also facilitates transformation through the stages of insight in contemplative psychology. As a construct and mental function it is engaged in both the constructive processes of structural ego growth and in the Indo-Tibetan tradition, the deconstructive processes of transcending identification through de-reification with those structures, which then allows a transformation in the fundamental identity of an individual whilst maintaining the optimal functioning of the self-structure.

Appendix 3: Three Phases of Buddhist Contemplative Psychology

The tradition of Buddhist contemplative psychology originates with the great Indian sage Siddhartha Gautama (known as Shakyamuni Buddha), born around 563 B.C.E. Through the view of the Indo-Tibetan Tradition, Buddhism has evolved through three major stages of evolution, or turnings of the wheel of the dharma. Similar to fundamental paradigm shifts seen in other forms of science (Kuhn & Hawkins, 1963), this evolutionary process, here into the causes of human existential unhappiness, is easiest understood as a progression of understanding with each stage supported by the cognitive and metacognitive findings of the prior stage.[13] The growth of Buddhist psychology was dependent upon the development of what the cognitive psychologist Jean Piaget referred to as the psychological capacity for formal operational thinking. The formal operational stage of cognition allows for the capacity for abstract thought: the use of hypothetical and deductive reasoning to reflect upon situations that are not present in concrete reality (Piaget, 1971). This stage of cognition includes the ability to problem solve in a logical and methodical way, and metacognition: the important psychological capacity to monitor and think about one's own thought processes. With the capacity for causal analysis and self-reflection available at this level of cognitive complexity, teachings could be developed that focused on understanding the cause and effect of the pervasive reactivity characteristic of the undeveloped mind. With a foundation in causal analysis, Buddhist contemplative thought then evolved from a reductionistic perspective on human suffering (abhidharma, higher teaching), to a systems perspective (madhyamaka/middle-way), and then to a later metasystemic perspective (buddha nature) (Guenther, 1989; Wilber 2014; D. Brown, personal communication, 2017). Each phase of the teaching is an expression of a cognitive paradigmatic shift in understanding human suffering and happiness and its causes, a turning of the wheel. As we will see later, these shifts map well to our modern understanding of cognitive development.

The First Turning of the Teaching: The Lesser Vehicle

The first phase, known as the Hinayana, or Lesser vehicle, due to the focus on individual well-being, was formalized at the third Buddhist council under the patronage of the Indian emperor Ashoka around 250 BCE. The teaching addresses the cause of existential suffering in the form of dukkha, the suffering of cyclic reactivity, caused by the ordinary mind's conditioned response to mental events. Dukkha is the result of samsara, conditioned reactive cyclic existence, the cycles of repetition compulsion that are caused by ignorance into the nature of awareness and the resulting reactivity that leads to compulsive activity.

The four noble truths. The Buddha's analysis of the cause and cure for suffering, the four noble truths, began with the observation that there is a human disease, *dukkha*, cyclic reactivity. It does not mean, as early western translations and interpretations would assert, that all life is suffering. The root of the word dukkha is etymologically related in Sanskrit to the prefix *dus* meaning bad, and the word *kha,* the original word for axle hole in the ancient language of the nomadic Aryans. The word dukkha literally means the uncomfortable experience of riding in a wagon when the wheel is off the central axis rather than aligned (Tirch, 2015). Shakyamuni was pointing to the fact that human life involves some experience of reactivity, traumatic stress, dissatisfaction, and imbalance, no matter how good one has it.

---

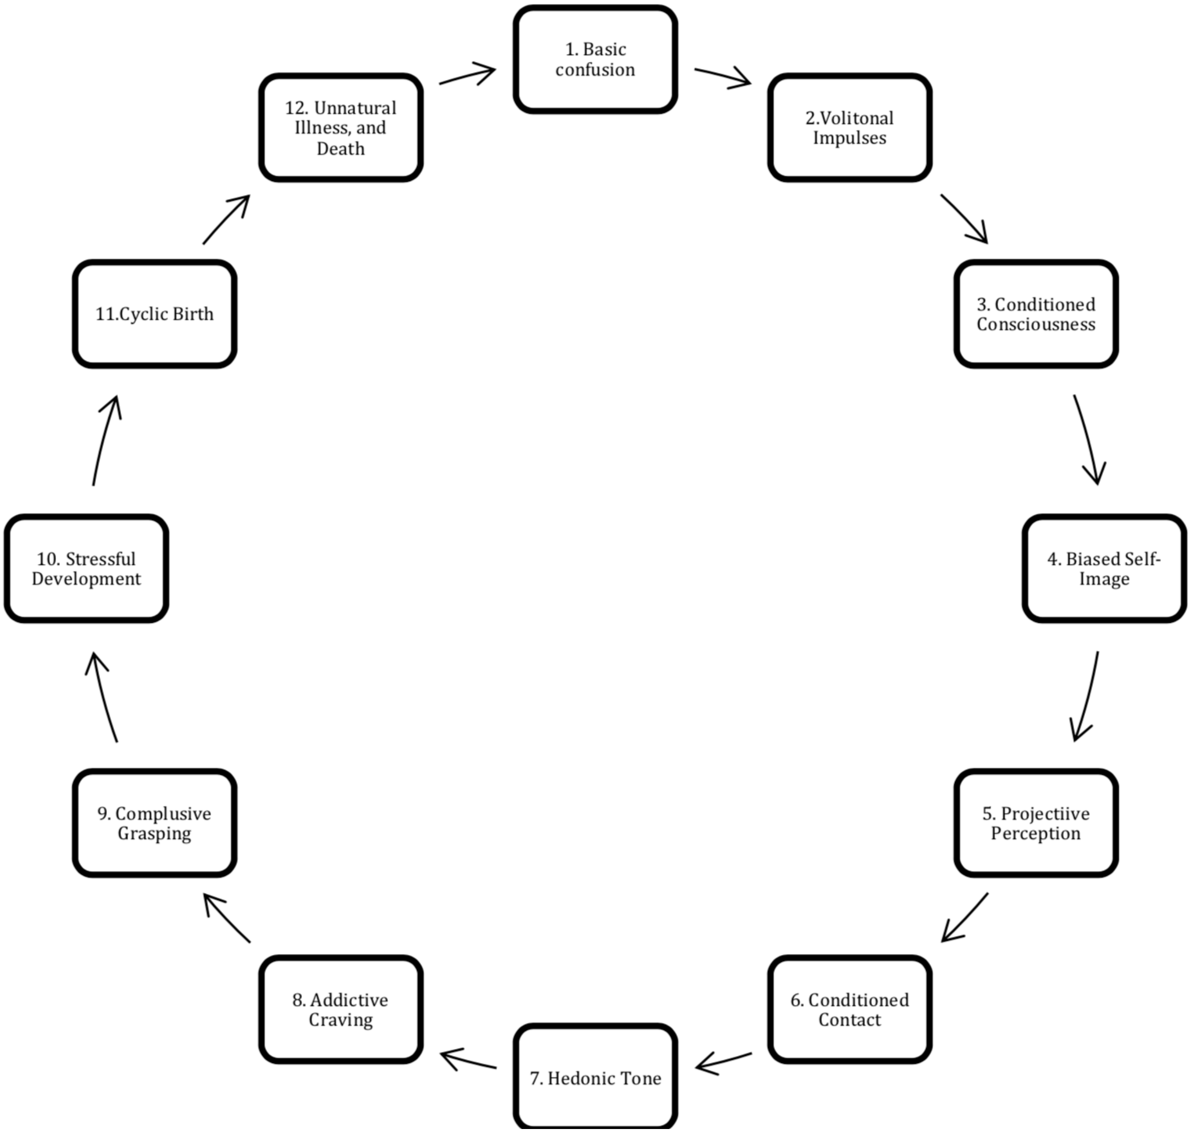
[13] Whilst the tradition maintains that Shakyamuni (c480 BCE – 400 BCE) taught all three turnings during his lifetime, and that a minority who had a greater capacity for a more sophisticated path initially practiced the latter two phases of the teaching, it is believed that understanding of the later turnings evolved as the cultural environment became more open to their innovations.

The second of the four noble truths is that the cause of dukkha is the mind's conditioning (karma) to reactive craving (tanha). This addictive grasping of the mind is, according to the Buddhist psychology of information processing (abhidharma), driven by the mind's conditioned reactivity to move towards events to create more experience (clinging), to move away from experience to avoid it (aversion), or to lapse into a loss of awareness though fusion with experience (ignorance or confusion). These three compulsive mental activities are said to dominate the normal reactive mind, obscuring the mind's natural condition of openness, clarity, and peace (Brown, 2006). The traditional Buddhist belief is that this cycle of compulsive mental and emotional activity is driven by cause and effect (karma) in a multi-life process. Buddhist psychology sees the cycle of psychological reactivity as driven by conditioning inherited from past human and animal lives since *beginingless* time.

Reincarnation aside, Shakaymuni's understanding can be interpreted as a naturalistic analysis of suffering describing the conditioning elements of both nature and nurture, the epigenetic transmission of trauma (Yehuda et. al. 2005), "the reincarnation of former ego-structures" (Freud, 1923, p. 48), and the intergenerational transmission of behavior (Loizzo, 2011). The idea presented by the Buddha that prior traumatic conditioning is at the root of the individual's bodymind is now being affirmed by the discoveries of science, through mechanisms including epigenetic conditioning of trauma (Kapoor et al., 2006; Miller, 2014).

The cycle of dependent origination. The abhidharma are the systems of Buddhist cognitive psychology that each tradition follows. The Indo-Tibetan tradition draws its abhidharma particularly from the Abhidharmasamuccaya by 4th century Indian Asanga. In the abhidharmic analysis of the causal workings of the mind it reveals that when fully understood there is no solid permanent self but a complex mind-body system of sensations, instincts, emotions, thoughts and perceptual processes known as the five skandhas. When disturbed by traumatic conditioning this system creates the illusion of a permanent self (Tsering, 2010).

This sense of a permanent self-existent self is activated due to reactivity caused by cycles of cognitive grasping, aversion and confusion that form a hidden 12-fold cycle, seen below in Figure A2, at the heart of Buddhist psychology. This cycle of traumatic repetition is known as the cycle of dependent origination (pratityasamutpada). From the perspective of Buddhist psychology this is the cycle that drives our ordinary unhappiness.



1. Basic confusion
2.Volitonal Impulses
3. Conditioned Consciousness
4. Biased Self-Image
5. Projectiive Perception
6. Conditioned Contact
7. Hedonic Tone
8. Addictive Craving
9. Complusive Grasping
10. Stressful Development
11.Cyclic Birth
12. Unnatural Illness, and Death

Figure A2. The 12-Link Cycle of Dependent Origination.

Figure A2 illustrates: 1. Basic Confusion (ignorance of any aspect of how the mind works, as exists at birth); 2. Volitional Impulses (automatic or unreflective reactions that further condition the mind to be reactive) > 3. Conditioned Consciousness (the resulting default "operating system" of consciousness, conditioned by reactive-stress and self-protection) > 4. Reified-Self Image (creation of an illusory reified self-image) > 5. Projective Perception (distortion of the sense perceptions, now further biased towards threat, distrust, and disconnection) > 6. Conditioned Contact (contact with the world is this distorted and contaminated with chronic reactivity) > 7. Hedonic Tone (bare sense perception is given a hedonic tone, i.e. is labeled as pleasant, unpleasant or neutral) > 8. Addictive Craving (the bodymind either moves away or towards further experience, in obsessive grasping or aversion) > 11. Cyclic Birth (reactive choices of the traumatized-self further condition the mind into a life-style of dissatisfaction) > 12. Illness and Death (the conditioning of unnatural traumatic stress leads to dysfunctional manifestations of aging and dying processes. and created the conditions for the related trauma and conditioning to be passed on to future beings, continuation of the cycle of dependent origination). (For a more in-depth explanation, see Churchill, 2018.)

The understanding of the 12 links is fundamental to understanding how all the different aspects of the Buddhist treatment strategy, the eightfold path, synthesize into an effective path to extinguishing reactive suffering and unfold the human potential for happiness, altruistic activity and evolution. Modern science, including research into default mode network of the human brain (Brewer et al., 2013) and studies of addiction (Witkiewitz et al, 2013) and trauma recovery (Tsering, 2010), supports this model of the cycle of reactivity, traumatic repetition and compulsive activity. The third noble truth, which indicates that psychological and biological cycle of reactive grasping, caused by the fundamental confusion of awareness with its conditioned contents can be suppressed, is also increasingly supported by such research. The suppression or removal of this cognitive pattern is called nirvana in Buddhism, which literally means cessation or extinction.

Fourth Noble Truth: Treatment path. The fourth Noble Truth is the Buddhist equivalent of a treatment approach, a holistic treatment plan of contemplative lifelong healing addressing an accurate view of experience, wholesome intentions, truthful speech, appropriate action, socially beneficial livelihood, consistent effort, and the practices of mindfulness and meditative concentration (Hanh, 1999) (Tsering, 2005). The treatment path leads to: 1.) The development of insight into the three characteristics (impermanence, reactive suffering, and true identity as awareness); 2.) The understanding of mental cause and effect as indicated in the cycle of dependent origination, and its relationship to unhappy and happy mental states; 3.) The threefold development of ethics, meditative concentration, and psychological insight leading to; and 4.) Nirvana, the extinction of the addictive emotional and psychological defilements that cause personal suffering (Loizzo, 2012).

The training associated with the turning of the first wheel addresses the problems of personal traumatic conditioning, and, as such, is often referred to as the Hinayana, or personal vehicle, since its focus is the individual rather than the greater community of sentient beings. From the mind perspective, the reactivity causes mental distractibility, and a discontinuity of awareness. *Mind* here refers to awareness, the basic capability for non-conceptual knowing, and attention, the ability of the mind to hold to a particular mental event. Mental events in Buddhist psychology refer not just to the experience of sensory information (visual, auditory, kinesthetic etc.), but also the processes of thought, memory, and imagination.

The goal of treatment/practice is to reduce the causes of reactivity, distractibility, disorganization, and constant mental elaboration, and to increase mental equanimity, the continuity of awareness, the capacity to stay on an intended object-of–focus, to increase organization of mind, and to silence mental activity when needed. The training consists of behavioral modification (ethical precepts), psychoeducation, basic mindfulness and attentional control. Behavioral modifications are designed to interrupt the cycle of dependent origination by not allowing the development of a lifestyle driven by compulsive grasping and traumatic repetition. Training in the conceptual understanding of the mind (abidharma psychology) helps support an accurate view of the mind and experience to understand the 12 links of dependent origination. Basic mindfulness is practiced to reduce reactivity to unpleasant hedonic experience at the 7th stage. The mindful practice of accepting experience and no longer avoiding unpleasant sensations cuts off the cause for the 8th stage of compulsive grasping. The practice of attentional stability (calm/staying concentration meditation) reconditions the default attentional system at the 3rd stage.

The Second Turning of the Teaching: The Great Vehicle

According to the Tibetan tradition, the second phase of the teaching was presented on Vulture Peak Mountain near Rajagriha, when the Buddha was said to have taught on the empty uncompounded nature of all phenomena (Skt: shunyata) and on compassion (Skt: karuna) (Hanh, 1999). These two elements form the heart of the Mahayana, the Great Vehicle, or second turning of the wheel. Historically, the approach is philosophically grounded in the madhyamaka school founded in the second century CE by Nagarjuna, the abbot of Nalanda University. The Mahayana includes the first turning insights into the reactivity and impermanence of human experience, but deepens the understanding of the deconstruction of the ego (no-self) and impermanence with a more sophisticated understanding that the concepts such as self, suffering, and the freedom from suffering, are themselves empty of an essential nature. In the Mahayana view the entire cycle of dependent origination reviewed earlier is caused by mistaken reification. The fundamental psychological problem with reification (Link 1) is that it causes *self grab,* which obscures the natural equanimity of awareness. It is the recognition of the lack of thing-in-itself-ness, the entitylessness, and constructed nature of all phenomena, whether psychological or physical, that is known by the term shunyata, translated as emptiness, but perhaps better served by the term *openness* to ensure that it is not interpreted as a nihilistic vision of human experience when in fact it is the opposite.

Emptiness/openness. In the contemplative approach of the madhyamaka, the mind trained through prior concentration practice (stabilization of Link 3) is used to direct a high-speed non-conceptual search through on-going mental experience and the psychological constructions of external reality, to see if any self-existent substantiality can be found (Brown, 1986). This search leads to the experience of the unfindability, unlocatability, and insubstantiality of mental experience, the hallmark of the realization of openness (Hixon, 1993). This is the realization of non-entityness, that the self, its experience, and all external reality are experienced as merely constructs without a substantial self-existent nature (Brown, 2006). "Deep examination of the essence of mind through wisdom will reveal the mind in an ultimate sense to possess neither intrinsic nor extrinsic reality; it is without structure" (Namgyal, 2006, p.64).

Following the realization of the emptiness of self and external reality, the contemplative investigation in the second turning of the wheel deepens into examination of the unconscious conditioning of the 1st, 2nd and 3rd links. This is accomplished through the practice of recognizing that time, the temporal unfolding experience of reality, is also a mere construct (Brown, 2006). The realization of this contemplative insight leads to the disembedding of the observing ego from the construct of time, and the experience of a timeless, unchanging awareness. Brown quotes Tashi Namgyal, the author of the Moonlight mahamudra meditation manual: "the way the realized mind stays (like space) is that there is no elaboration of the three units of time (arising, staying, ceasing, nor any dualities, (eternalism/nihilism, coming/going)" (2006, p. 345). The realization of the mind's timelessness opens the meditator to the experience of the simultaneous interconnectedness of all potential events. This realization in the Mahayana is what matures into the realization of compassion and the importance of the transformation of society, as all beings are intimately and simultaneously interconnected. This important aspect of the path is central to the teaching on the Bodhisattva path, and career of compassionate non-dual service that leads to the awakening of not just the individual but the collective.

The Third Turning of the Teaching: The Buddha Nature Vehicle

It is believed in the Tibetan tradition that the third turning was taught by the historical Buddha to an audience of Bodhisattvas at a number of locations in India. Historically, the philosophical foundations are found in the yogachara school, originating in the fourth century with Asanga guided by his visionary experiences of Maitreya, the mythic Buddha of the future. Whilst the madhyamaka school asserts the fundamental unconstructed nature of human experience, the yogachara school asserts that the mind, awareness, has a primordial reality, and that this mind essence, or buddha nature (Skt: tathagatagarbha) is ultimately real and the source of all positivity and goodness in the human mind. Later Indian masters from Nalanda University integrated the madhyamaka and the yogachara view into the yogacara-svatantrika-madhyamaka. This position held the madhyamaka position that reality is essentially empty but that the methodology of the yogachara school helped students progress along the path to that realization (Mipham, 2005). Whilst the Indo-Tibetan tradition has multiple lineages with slightly differing approaches, in essence they address the same issue.[14]

The yogachara terminology is used by the Tibetan *essence of mind traditions* to explain their most refined practices, the generation and completion stage (tantra), great seal, (Skt: mahamudra) and great completion (Tbt: rdzog chen) traditions. Whilst the three approaches of tantra, mahamudra, and rdzogchen have differing terminology and methodology in realizing the buddha nature, they generally agree that the fundamental basis of awareness is a non-dual union of openness/spaciousness/mother consciousness and the clear-light awareness/lucid knowing/infant consciousness, the union of which is also known as the dharmakaya, the body of truth. It is the recognition of this fundamental awareness at the 1st link that cuts the entire traumatic repetition of dependent origination.

The mother, openness, is the phenomenological open basis, ground, and foundation of all experience. The Bon rdzogchen lineage of Zhan Zhung Nyan Gyud, describes it as the *space of the nature of phenomena* with nine qualities: boundlessness, omnipervasiveness, and unlimited expansiveness, without top or bottom, immeasurableness, uncontractedness, great vastness, everlasting and immutable (Wangyal, 2000). This open phenomenological space is described as *the Mother* because it is the mother of all phenomenological existence, freedom and conditionality, matter and mind, good and bad, truth and illusion. Thus, this openness is not an inert void, "is not some abstracted and lifeless emptiness, but an utter fullness that.... is vibrant with energy" (Guenther, 1989 p. 203). In a similar way the open field of outer space is full of the fecundity of galaxies, stars, and solar systems. It is not an abstract void – instead a field full of life.

---

[14] From the point of view of individually ascribed names, there are numerous traditions, such as those of the simultaneously arising as merged, the amulet box, possessing five, the six spheres of equal taste, the four syllables, the pacifier, the object to be cut off, rdzogchen, the discursive madhyamaka view, and so on. Nevertheless, when scrutinized by a yogi, learned in scripture and logic and experienced (in meditation), their definitive meanings are all seen to come to the same intended point. (The First Panchen Lama, Lozang-chokyi-gyeltsen, (Berzin translator), 1997, p.98).

On the other hand, the *infant consciousness* is the primordial, lucid nature of the mind, an awareness that is brilliantly awake, referenceless, pristinely non-conceptual, and the most basic form of cognition or knowing. At the deepest fundamental levels of the human mind the unbounded openness is inseparable from this referenceless clear knowing.

In the Indo-Tibetan tradition the first turning of the wheel focuses on treating traumatic reactivity and suffering through understanding the cycle of dependent origination that conditions experience, the ethical practice of behavioral modification (links 9,10,11), mindfulness meditation (link 7), and the attentional development of calm/staying (link 3). In the second turning treatment focus is on practicing recognizing the fundamental openness of experience to liberate the mind from the human habit to reify all experience of self, other, and the world. This matures into the understanding that the entire cyclic nature of suffering is caused by the failure to recognize the fundamental openness of the mother which results in ensuing reactive reification and the obscuration of the clear light of the infant consciousness. In the third turning of wheel it is understood that suffering is due to basic confusion and ignorance, (Skt: avidya, Tbt: marigpa) as to the true nature of the buddha mind that is always already right here (link1). The recognition of the buddha nature is obscured by the ordinary operations of consciousness, including even the activity of meditation itself. The aim of treatment of this cognitive dis-ease in the mahamudra and rdzogchen traditions is of a similar nature, but the methods differ slightly.

Appendix 4: Buddhist Essence Psychology: mahamudra and rdzogchen

As mentioned above the Buddhist tradition of contemplative psychology can be divided into three developmental stages (lesser, greater, and buddha/essence vehicles), and this section investigates the contemplative psychology of the third paradigm, the essence traditions of mahamudra and rdzogchen, and how these teachings have their foundation in the fundamental insights of the first and second turnings, but also expands upon them by exploring the nature of mind: the clear light spacious nature of awareness itself.

Within the Indo-Tibetan tradition there arose in the 19th century, in response to the authoritarianism of the ruling Gelugpa order, an ecumenical movement known as the rime (all-embracing, unlimited, impartial (Schaik, 2011). This universal approach to contemplative practice respected the separate lineages and yet was able to draw upon the best elements of the five schools. This movement continues today and is best personified in His Holiness the 14th Dalai Lama, who studied with many great masters across the tradition, and took His Holiness Menri Trizin, the leader of the indigenous Bon tradition, as one of his mentors in rdzogchen (great completion) practice.

An outcome of this non-sectarian movement was the synthesis of the mahamudra and rdzogchen traditions. Meditation masters such as the 3rd Karmapa, 5th, 13th and the 14th Dalai Lama worked with both mahamudra and rdzogchen practice.[15]

History of Mahamudra

Mahamudra (phyag chen), the *great seal, great embrace*, or *great symbol* is a tradition of concepts and practices within the Indo-Tibetan Buddhist tradition. Maha means great in the sense of a great openness beyond limitations, and mudra refers to the expressive nature of phenomenal experience as viewed from the awakened mind (Ray, 2002).

Mahamudra is divided into sutra, tantra, and essence approaches. Sutra mahamudra is based on the Buddha Nature teachings of the third turning of the uttaratantra shastra of Maitreya (Gyamtso, 2000) and outlines a path to realization attained through the practice of the six paramitas as the bodhisattva aspirant journeys five paths and ten stages to buddhahood). Tantra mahamudra is based on the anuttarayoga tantras (unsurpassable union process) of the New Translation school and outlines a path of practice based on the transformation of the self-image, inner narrative, neurochemistry and energy system of the individual through visualization and yogic exercise (Loizzo, 2012). Essence mahamudra refers to the approach of direct investigation into the nature of mind and it is comparable to the rdzogchen teachings of the rNing ma and Bon traditions (Ringu, 2017).

The essence tradition of mahamudra originates with the great adept Saraha, who it is believed lived in India in the first millennium CE. He is regarded by the Tibetan tradition to have been the teacher of the philosopher and abbot of Nalanda monastery, Nagarjuna, and the mountain hermit Savaripa. Maitripa (986-1063), received visionary instruction from Savaripa, and outlined in his written works the doctrine of ‘not taking to mind’ (amanisakara), mentioned below.

---

[15] For example the text *Buddhahood in the Palm of the Hand, The Union of Mahamudra and rDzogchen* by the 17th century master karma chags-med (Chagme, 2000) outlines a path of practice using mahamudra to recognize and stabilize the realization of buddha nature, and then the use of rdzogchen practice to bring that realization to fruition.

In Tibet there are numerable lineages of mahamudra practice in the Kagyu, Sakya and Gelug traditions of the new translation school. Important to the lineage of mahamudra practice described in this section is the Tibetan translator, Mar pa Chos kyi bLo gros (1012-97) who studied essence mahamudra with Maitripa, and tantra mahamudra with the ex-abbot of Nalanda, Naropa (d. 1040). The new approach to mahamudra outlined in sGam po pa’s *Explanation of the Sole Path of Mahamudra* outlines the practices in a four yoga model comprising preliminary practices to prepare the mind and body, ordinary calm/staying practice to calm the events of the mind and develop attentional stability, ordinary special insight practices to recognize the empty lucid nature of awareness, and the extraordinary practices to recognize the non-duality of appearance/awareness-emptiness, and to effortlessly mature the realization (Brown, 2006).

> A lucid, unceasing momentary awareness is the one-pointed stage of yoga. Understanding the essential nature of that awareness as nonarising emptiness that transcends conceptual modes or reality and unreality is the nondiscriminatory yoga. Understanding diverse appearances as being one from the standpoint of their intrinsic nature is the one-taste yoga. An unceasing realization of the union of appearance and its intrinsic emptiness is the great equipoise of nonmeditation yoga. (sGam po pa in Namgyal, 2006 p. 358)

The four yogas are also known by the names of shamatha, vipashyana, yugganaddha, and mahamudra.

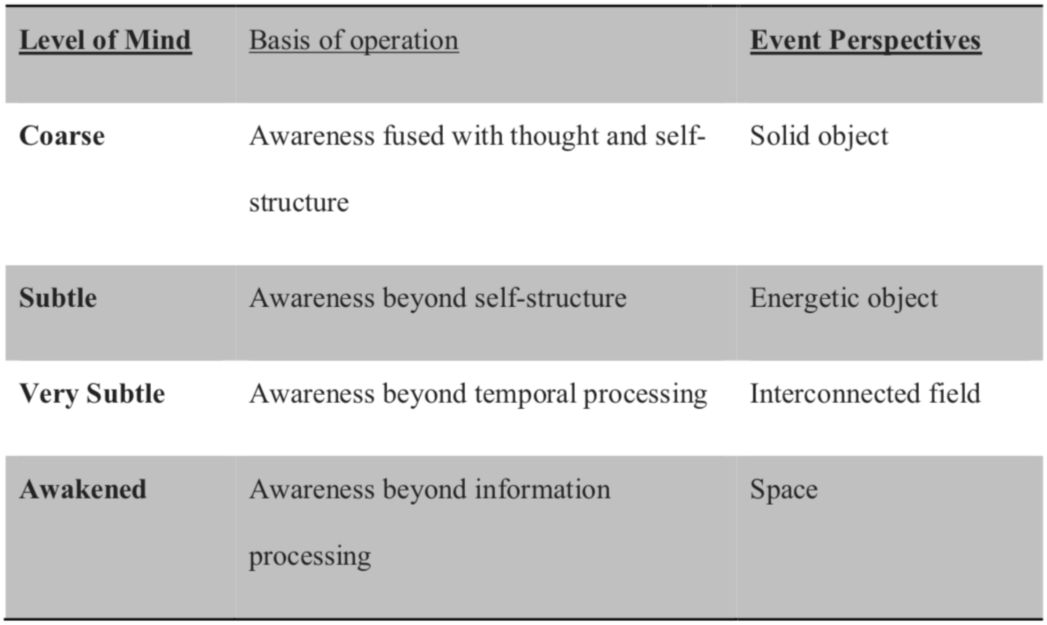
View: The Path of Development in Mahamudra

In order to understand mahamudra it is necessary to understand the concept of *tawa (Tbt.)* or *dristi (Skt.)* which literally means, *view,* meaning the view from which one experiences phenomena. Brown (2017) explains that the view is dependent upon the basis of mental operation (spod yu), the loci of identity, level of awareness or vantage point from where the mind’s metacognition is operating. According to Ras chung, student of Mi la ras pa, there are four main bases of operation, see Table 2 below (awareness fused with thought and self-structure, awareness beyond self-structure, awareness beyond temporal processing, and awareness beyond the information processing system), with each level sequentially freer from the subtler and subtler reifications of unconscious psychological and perceptual structures. Each basis of operation has the capacity to view phenomena (take the event perspective) and self-recognition (the mind perspective). The event perspective refers to the perspective of mental objects perceived at that particular level of awareness i.e. concrete objects such as the thoughts and subtle objects such as abstract patterns. The mind perspective refers to the perspectival capacity to self-reflect and recognize the level of awareness from which the mind is operating i.e. to make awareness, the subject, the object of itself.

Indo-Tibetan psychology is based on an understanding of four levels of mind (four bases of operation); the coarse, subtle, very subtle and awakened. These are four levels of mental experience are always present in experience, but they are not necessarily conscious. Whether a level of mind is made conscious or not is dependent on the level of view, the basis of operation from which identity is operating. Therefore, the basis of operation moves through the various levels of mind. In essence practice the meditations are less about meditating on something as they are about learning to operate from a new level of awareness, a new basis of operation, and from there to take a new perspective or view on experience.

The course level of mind is the level of day-to-day experience based in the linguistically created world of thought by the self. At this level of mind, the events we perceive are solid, a reified world of objects based on language. The next level of mind is the subtle level of mind that is perceived in information processing prior to naming of the coarse level. At this level the events are just the high-speed movement of perceptual information such as the abstract patterning of pure sensation, sound, and color. The mind at this level is functioning prior to thought, and the construction of self, and if the basis of operation is operating at this level it functions beyond the structure of self. The third level of mind is the very subtle level of mind. At this level the mind is a vast interconnected spacious field of very subtle energy and the basis of operation that perceives this is level of mind is a timeless, non-dual individual basis of operation. The fourth level of mind referred to earlier as the buddha nature, dharmakaya, is a non-dual unity of referenceless awareness (rigpa) and unbounded space (ma) where the field and the basis of operation perceiving the field are undivided. These four levels of mind and their perceived objects are shown below in Table 2.

Table 2. Levels of Mind, Basis of Operation & Event.



Level of Mind	Basis of operation	**Event Perspectives**
Coarse	Awareness fused with thought and self-structure	Solid object
Subtle	Awareness beyond self-structure	Energetic object
Very Subtle	Awareness beyond temporal processing	Interconnected field
Awakened	Awareness beyond information processing	Space

The table above shows a basic relationship between the level of mind, the event experienced at that level of mind, and the basis of identity operation at that particular level. The basis of operation shifts during meditation and initially this will be a brief *state* but as practice continues the state will become a *trait,* and a permanent developmental stage of identity. The levels of mind, basis of operation, and objects are also hierarchically nested, which means that when operating from awakened awareness beyond information processing that the awareness can cognize space, the interconnected field, energetic objects and solid objects. However, when awareness is fused with thought and self-structure it will be unable to perceive the subtle, very subtle levels of mind.

sGam po pa’s Four-Yoga Model

Churchill (2018) examines in detail the four-yoga model of sGam po pa’s mahamudra, a practice that unfolds through the developmental sequence of disembedding awareness as basis of operation from subtler and subtler psychological structures. The meditator first calms the mind (shamatha), then by gaining insight (vipashyana) into the constructed nature of the self, time, and individuality recognizes awareness to be already beyond all structures to a basis of operation, buddha nature, without any reference points (Brown, 2006). The four methods are described as: One-pointed yoga (calm/staying; shamatha), Non-discriminatory yoga (insight; vipashyana), One taste yoga (union of calm staying & insight), and Non-meditation yoga (mahamudra), each summarized below.

One-pointed yoga: calm/staying (shamatha). The practice of calm/staying refers to the calming of mental events in the mind such as thought and conflicting emotions, and the staying of the attentional system on the chosen object of mediation. The basic cognitive skills to be developed are motivation, directing attention, intensifying the attentional interest to the object, and metacognitive awareness.

Motivation needs to be developed to get the practitioner to begin and continue the process of practice. "Steering" involves the repeated redirection of the wandered attention back to the meditation object. The practitioner learns to have volitional access of the attention, developing the capacity to shift from vague interest to admiration to fascination of the object by increasing the salience of the details presented whether that is the breath, sensations of the body, a visual object, thought (mantra), or visualization. This would be akin to zooming in to have a close look at an object under the microscope. Metacognition in the context of calm/staying meditation is related to the *non-conceptual* intelligence, or clarity of knowing what is arising within the experience of the meditator, and therefore being able to adjust the meditation accordingly. As students learn to develop calm staying, they sequentially work through the ability to steer, intensify the attention, and brighten metacognition.[16]

Non-discriminatory yoga: insight (vipashyana). Once the meditator develops the capacity for calm/staying he or she is ready to use the stable mind to gain insight into the constructed nature (emptiness) of psychological reality. The function of insight meditation is twofold. First, to come to understand that all psychological phenomena that arise in experience (perceptual, cognitive, affective, and physical) are psychologically constructed (i.e. "empty," or based on confusion/ignorance). This first stage of the practice is a negation of the thing-in-itself-ness of the object. It leads to an experience of the psychological openness of experience that releases the ’grab” of the object over the attentional system, which in turn allows for the second stage, which is a clear recognition of the nature of the awareness that perceives the object.

---

[16] The tradition has a number of ways of breaking up the stages of calm/staying but essentially the meditation has two main phases: with support, and without support. Calm staying with support describes the development of continuous and complete staying on the meditation object where the object still appears to be permanent and therefore the mind is operating at the coarse level of operations. Calming staying without support refers to the development of the capacity to stay so close to the object that the meditator becomes aware of the impermanent nature of the meditation object as momentary perceptual pixels of information.

The realization of the emptiness of self happens through a meditative search into the meditator’s direct experience to see if the self can be discovered as a substantial independent entity. This culminates in the direct experience of the nonentityness of the self, the experience of emptiness. The realization of the emptiness of experience can then be generalized to all other psychological structures and experience such as thought, the body, emotional states, pain, etc.

Brown (2006) in his synthetic review of mahamudra through the structure of the four yogas breaks the phases of special insight into the emptiness of self, phenomena, and time. This last stage, the emptiness of time, sets up the basis of psychological operation needed at the beginning of the yoga of One Taste. Awareness of the emptiness of time deepens the contemplative analysis of experience via insight in meditation that the deepest substrate of awareness does not arise and pass away like temporal experience, but functions outside the psychological constructs of past, present, and future and is continuously operating even during waking, dreaming and deep sleep states (Mason, 2010).

One taste yoga: union of calm staying & insight. The basis of psychological operation for the one taste yoga (yugganaddha) is the very subtle, timeless level of awareness. This basis of operation is established by investigating that awareness itself is changeless and beyond the conventional coming and going of psychological time. Exploring the timelessness of the spacious phenomenological field of perception, and then recognizing the nature of the awareness that perceives such field can also establish timeless awareness. This is called *establishing the view.* The prior calm/staying training is needed for the stability and capacity to hold the perspective long enough for it to become established.

Tashi Namgyal explains that there are three things to be determined about the abiding nature of this very subtle mind: the essence of mind is empty, its self-nature is luminous clarity, and its aspects consist of the diverse display of experience appearance. The practitioner recognizes that this field of non-conceptual awareness and phenomenological space is inseparable and extends in all directions without boundary. Again quoting Namgyal (p. 216), “Whatever is the nature of space is the nature of awareness. Whatever is the nature of awareness is enlightenment. For this reason awareness, the expanse of space and the mind of enlightenment, are nondual and inseparable”

Once the view of the empty lucid nature of the very subtle level of mind is stable the practitioner learns *reverse samadhi*, to ease up on the relative activity of ordinary coarse level thinking, but to simultaneously maintain the view. Then whatever mental events arise moment-by-moment within the field of the very subtle level of mind is experienced as the non-dual expression of this field. Non-dual here means that the unbounded field of awareness-space and the objects in awareness arise together, and are *co-emergent* (Namgyal) and *simultaneously* (Brown, 2005) arising.

Tashi Namgyal (p. 225) lays out three stages to the actual identification of the spontaneous coemergence: identifying the mind co-emergence of the mind, which addresses the mind perspective, and the cognitive co-emergence of mental activity and perceptual appearance, which address the event perspective. "When the meditator perceives the clarity of perceptive form and its unidentifiable emptiness as being the inseparable, denuded union of appearance and emptiness or emptiness and appearance, he has gained insight into the intrinsic coemergence of appearance" (Namgyal, p. 233). Brown (2005) calls these mind-simultaneous, cognition-simultaneous, and appearance-simultaneous.

The meditation on the simultaneous co-emergent mind is a process of deeper and deeper familiarization with the inseparability and one taste of the empty lucid awareness and the manifestations of appearance. Initially the student realizes the inseparable nondual nature of the simultaneous co-emergent mind with all cognition and appearance. As the meditation deepens the reactive identification with objects releases and then finally as it matures there is no distinction between awareness and its content.

Non-meditation yoga (amanisakara***).*** At the heart of the mahamudra approach to addressing basic confusion, and associated with adepts Saraha, Maitripa, and Tilopa is the doctrine and practice of amanisakara. Amanisakara is the non-meditation discipline that follows the prior three yogas and provides the meditator with the conditions to realize the nature of mind. Amanisakara (Tibetan: Yi la mi byed pa) is translated as *non-mentation*, *non-egocentricity*, *not taking to mind*, and *non-particularization.* It is at the heart of the third turning approach to contemplative practice (Higgins, 2008; Brown, 2006).

In the psychology of the abhidharma, the manisakara is the last in a sequence of five omnipresent mental factors of information processing (contact, discernment, feeling, intention and attention) (Tashi, 2010) that are active in every moment of experience. Manisakara has numerous translations, *attention* (Tashi,) *ego centric demanding* (Guenther & Kawamura, 1975), *bringing to mind*, *setting one's mind upon, focus* (Higgins, 2006) *taking to mind, mental engagement, particularizing* (Brown, 2006), *paying attention*, or *taking to mind* (Berzin, 2017). Essentially, manisakara is the activity of the information processing system that engages with a mental event and in doing so simultaneously creates the experience of subject and object, the attention and the attended. If awareness is con-fused with this attentional movement, it then identifies itself solely as the attentional system and then the larger field of open phenomenological experience (Ground) will be obscured. Brown (2006, p. 438) refers to this attentional subject as *individual consciousness*.

In the term *amanisakara* the beginning *A* is a negative particle, and is referring to the negation of the information processing and attentional system (manisakara) of individual consciousness. This is achieved through orienting the nondual timeless awareness beyond identification with the artificial mental engagement of information processing, and towards any specific object towards the whole field of experience. Nonmeditation (sgom med) means precisely this: doing away with any artificial activity that can be considered meditation" (Brown, 2006, p 412).

> When the mind does not move toward any seeming appearing object, and more specifically does-not-take-it to-mind, the most rudimentary basis for any discrimination falls away, and the practitioner completely transcends all false conceptualization. Mastery of not-taking-to-mind completely purifies the mind of any tendency to move toward or away from seeming

> objects. Specifically, it eradicates any movement of the mind-perceiver and clears the way for undistracted awareness of the natural mind. Brown (2006, p. 415).

By perfecting this non-meditation, the meditator attains naked, unsupported awareness. This nondiscriminatory awareness is the meditation! By transcending the duality of meditation and meditator, external and internal realities, the meditating awareness dissolves itself into its luminous clarity.

rDzogchen

rDzogchen, or great completion practice, is the culmination of contemplative practice in the indigenous Bon tradition and the oldest Buddhist tradition in Tibet, the rNing ma. In both systems it is the apex of nine stages where each system is a practice path unto itself, and there are different paths of practice for different levels of understanding. In the Bon tradition the lower stages focus on shamanic practice while the rNing ma model addresses the foundational Buddhist practices of the Hinayana. Both traditions then progress through Bodhisattva teachings on emptiness and compassion, and then Tantric approaches using visualization and yogic techniques to culminate in rdzogchen.

rNing ma schools have classified the rdzogchen teaching into three series of teachings. The first is the *sems sde*, or *mind series*, which provides the most detailed step-by-step explanation and instruction in the path with an emphasis on non-conceptual awareness knowing. This approach is similar to the four-yoga model of sGam po pa described above. The second series is the *klong de*, or *space series*, where the approach is more direct, immediate and emphasizes non-conceptual space. The methods rely upon remaining within the meditative view through the use of sensation and other direct sensory experience. Particular postures, belts, and sticks are used as a support to create powerful sensory experience through which the practitioner can easily recognize directly the phenomenological unbounded openness of experience (Chogyam & Dechen, 2002). The third series is the *mengak de*, *the secret precept series*, which contains little instruction, just simple descriptions and methods on how to maintain the view.

The Bon A Khrid System of rDzogchen. Bon is the indigenous tradition of the Tibetan plateau that originated from an ancient empire, Zhang Zhung, that includes areas known today as Iran, Tajikistan Afghanistan, Tibet, Kashmir, Pakistan, and India (Reynolds, 2014; Brown, 2017). The founder of the tradition was a Buddha known as sTon pa gShen rab who predated the Indian Shakyamuni Buddha by many centuries. The Bon tradition is composed of both shamanic ritual practices for gaining benefit and prosperity in this life known as the causal Bon (rgyu'i bon), and those higher spiritual teachings of Tönpa Sherab, known as the fruitional Bon ('bras bu'i bon) which consist of sutra, tantra and rdzogchen practices akin to those found in the Buddhist lineages originating from India (Reynolds, 2014; Brown, 2017).

There are four transmission lineages of rdzogchen within Bon; the Zhang-zhung snyan rgyud (Oral transmission from Zhang Zhung), the rDzog chen yang rtse klong chen (The Great Perfection from the Highest Peak of the Great Vast Expanse), the Ye khri mtha sel (Removing Limitations from the Primordial State) and the A Khrid (the Guiding Explanation for the Primordial State) (Reynolds, 2005).

The ninth lineage folder of the A Khrid system Bru rGyal ba g.Yung drung (1242-1290) condensed the system to a 15-session manual which became the most popular version of the A Khrid teachings. As an example of the rdzogchen tradition this exploration will focus on the A Khrid system from Bon rdzogchen. It provides a systemized approach that parallels and expands upon the mahamudra four-yoga model.

Brown & Gurung (2017) in their translation of the A Khrid pith instructions reveal how the commentary of the A Khrid divides practice into three main phases: bringing the unripened mind stream to ripening, bringing the ripened mind stream to liberation, and bringing the liberated mind-stream to the completion of Buddhahood.

In the practices of "ripening the unripened mind stream" the unripened mind is brought to ripening through four sessions of practice: *Meditation on Impermanence, Setting the Intention and Taking Refuge, the Mandala Offering, and Guru Yoga* (*mentor bonding* practice). These are explained more in Brown (2017) and Churchill (2018).

The practice of "Bringing the Ripened Mind-Stream to Liberation" the ripened mind is brought to liberation through six sessions. These sessions traverse the same psychological territory as the four yogas of mahamudra. Session five and six, *Concentration With* and *Without Attributes*, are devoted to calming the events of the mind and developing attentional stability. Through the seventh session, *Bringing Forth the Benefit*, the practitioner recognizes his or her basis of identity and psychological operation as being beyond the constructions of self, and time. Through the practice of mixing awareness into the visual perception of the outer open sky itself, and recognizing the perceptual non-duality between the awareness that is seeing the sky and the openness of the cloudless sky, one come's to recognize the spacious field of lucid, intense, and brilliantly awake awareness that is always present in each moment. The eighth session, *Pointing Out the Meaning of the Natural State*, relies upon the practice of breath retention (vase breathing) and meditation on the central channel.

The ninth session,. *Getting Rid of the Stains Created by the Ordinary Mind,* is devoted to the stabilization of awakened awareness, through: "Setting Up the View" (to repeatedly shift the basis of operation to awakened awareness more often and for longer periods of time); "Dismantling the Ordinary Mind" (the dismantling of the individual consciousness, akin to sGam po pa's Non-Meditation): and "Automaticity: (awakened awareness is able to sustain itself automatically at all times and in all situations). This leads to the tenth session or stage *Taking Stainless Primordial Wisdom as the Path*, in which the meditator practices maintaining and integrating this basis of operation whilst engaging in systematically more difficult circumstances.

This tenth session (of the second, or liberation, phase of the A Khrid system) completes the process of liberation. At this point of development the meditator has developed the capacity to operate naturally from awakened awareness, the level of lucid, open non-dual awareness prior to the constructions of the information processing systems of perception, attention, temporal awareness, self-construct, emotion and cognition. Perhaps surprisingly to some readers, rDzogchen moves on from there.

The third phase of the A Khrid system moves from "liberation" to "Buddhahood" (i.e. "Bringing the liberated mind-stream to the completion of Buddhahood"). This third phase of practice, also named, the *Practical Guide for Liberation*, *Reaching the End*, includes maintaining awakened awareness into deep sleep and dream yogas. According to the tradition (1) bringing awareness into the state of deep sleep is the transformation of the most ignorant substrate of consciousness, and parallels the capacity to maintain awareness throughout the dying process (Wangyal, 1998); and (2) the dream state is the most responsive state from which to transform the deep habitual karmic tendencies that have built up in the mind (Norbu & Katz, 1992; Wangyal, 2004). Though they are included in post the post-liberation (Buddhahood) phase of the A Khrid system, deep sleep and dream yogas are also practiced during the Liberation (second) phase to deepen the processes of dis-identification. The "fruition" processes ("dharmadhatu exhaustion ") introduced at this last phase is meant to cleans one of all past karmic imprints, to ultimately reach a stage of in which all negative mind states have been purified and all the positive qualities of mind have been developed (kindness, generosity, patience etc.). Though this tradition locates these purification processes after building the skills of liberation (the capacity to operate naturally from awakened awareness), other systems speak to the ongoing process of purification of conditioning (i.e. karma) that happens all along the path.

The final movements along this path include "Staying uninterruptedly in a state of one-pointedness (on the view of the inseparable pair of unbound space and awakened awareness) across the three gates of body, speech and mind, is concentrated evenness; conduct throughout the various activities and behavior is post-meditation" Druchen Gyalwa Yungdrung (Brown, 2017, p. 170); and "[not] even the slightest distinction between holding or not holding mindfulness, sleeping and waking, and being distracted or undistracted from the real nature of the mind" (Brown, 2017, p. 174).

This fruition manifests itself in realization of three dimensions: the realization of the "three enlightened bodies," the primordial wisdoms, and enlightened activity in the form of skillful means, great compassion/loving kindness, and omniscience. The three enlightened bodies, dharmakaya, samabhogakaya, and nirmanakya, (kaya) can also be translated as three fields or dimensions of the enlightened mind (the unbounded, unborn, uncreated open ground of reality akin to the purification of deep sleep; the field of light in the form of brilliant, primordial, lucid, lively awareness akin to the purification of the dreaming mind; and as radiant self-arising-self-liberating liveliness akin to the purification of the waking mind).

Finally, we will mention the rDzogchen system of "Five Primordial Wisdoms" describing the workings of the fully purified mind (i.e. Buddhahood) (Thrangu, 2011). It is described in terms of how the purification and transformation of each major defilement leads to an enlightened wisdom capacity. This model is a useful psychological tool for any location along the path to liberation.

The transformation of anger and default consciousness produces mirror-like clarity. The transformation of hedonic tone (likes, dislikes, grasping, pride) leads to perfect equanimity. The transformation of mental formations (and preference) from a self-seeking manipulation of reality leads to compassion and a discriminatory awareness as to what is ultimately good for the interconnected field. The transformation of the perceptual system (and jealousy) lead to a purified executive functioning that automatically translates understanding into energetic right action.

Looking at the underlying architecture of the mahamudra and rdzogchen systems presented a common pattern emerges. In the process of contemplative psychological development it is necessary to first recognize, and then stabilize, a basis of operation before it can integrate the relative activity of body, speech and mind into a non-dual realization. For instance, in the mahamudra the practitioner realizes the very subtle timeless mind, and once that view is established as the basis of operation then the relative activity of mind is allowed to arise within that timeless very subtle spacious field. The four yoga mahamudra tradition has a greater differentiation of levels of metacognitive operation prior to awakened awareness than the A Khrid system. As such the four-yoga mahamudra articulates the process of establishing a basis of operation and its non-dual function at the subtle (emptiness of phenomena/dreamer and dream), very subtle (one taste reverse Samadhi), and the awakened level of mind.

What can be seen in the mahamudra and rdzogchen is a process intrinsic to human development. There is an orientation to a whole field (subtle, very subtle, awakened) that leads to the recognition of a metacognitive basis of operation. That new basis of operation then orients to the perceptual and cognitive expressions within the whole phenomenological field whilst simultaneously recognizing objects as an integrated expression of that field. When integrated, the intention shifts to establishing the next whole field as a basis of psychological operation. Because the whole fields are nested contexts (the awakened level includes, the very subtle, the subtle, and the coarse) this allows for the A Khrid system to cut through to the awakened level and in the non-dual integration of liveliness all prior levels of development are subsumed.

Leadership Coaching Leads to Later Stage Development

Antoinette J Braks[1]

Abstract: This paper explores a multiple case study based on the effects of a developmentally informed, transformative leadership-coaching methodology. After an average of eight 90-min coaching meetings over 12 months with a Synergist executive coach, 83% of the 12 strategic executive leaders in the case study shifted a full stage, mostly from Achievist to Catalyst; the other 17% shifted two stages from Achievist to Synergist. The paper presents the eight drivers emerging from a thematic analysis of >100 hours of coaching conversations (>100,000 words) that enabled universal later stage development. It draws on the STAGES model to explain the significance of transforming the organisational context and undertaking shadow work. The dynamics of development led to an emergent Vertical Development Theory.

Keywords: Executive coaching, leadership, Stageshift, Synergist, vertical development theory.

Introduction

This paper first explores what is known about later stage development in terms of the structure and pace of development, and the factors thought to stimulate later stage development. ‘Later stages’ are defined as the postconventional stages of development. The paper then articulates the coaching interventions or drivers of development that led to shifts from Achievist to Catalyst and onto Synergist distilled from the executive coaching case study. This is followed by an exploration of why and how these drivers were effective in relation to the dynamics of vertical development with reference to the STAGES model. The paper concludes with an emergent Vertical Development Theory, a set of implications for executive coaches and facilitators of advanced leadership development programs and makes a number of recommendations for future research.

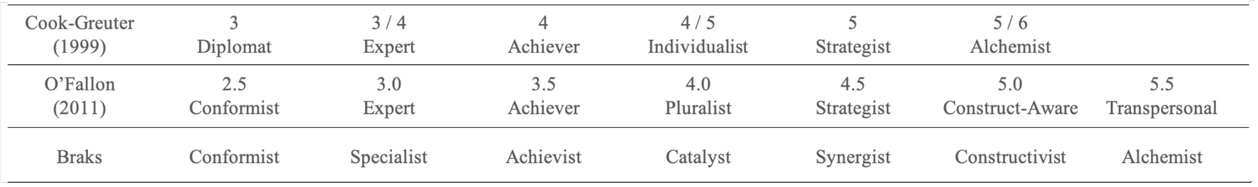
Table 1. Key for use of Stage Terms in this article (author's perspective).



Cook-Greuter (1999)	3 Diplomat	3 / 4 Expert	4 Achiever	4 / 5 Individualist	5 Strategist	5 / 6 Alchemist	
O'Fallon (2011)	2.5 Conformist	3.0 Expert	3.5 Achiever	4.0 Pluralist	4.5 Strategist	5.0 Construct-Aware	5.5 Transpersonal
Braks	Conformist	Specialist	Achievist	Catalyst	Synergist	Constructivist	Alchemist

The stage terms chosen by the author were selected based on their corporate audience, and their "-ist"-ness. In particular, Synergist was chosen instead of Strategist as the word strategist has its own meaning in the corporate world. It denotes a person fluent in devising corporate strategy which is best categorised as an Achievist-level capability. It also fails to incorporate the collaborative synergy that is a distinctive and valuable emergent capacity at this stage of development to enable more sustainable, empowering and equitable foundations to be built. Achievist, a term originally used by Beck and Cowan (1996), was adopted for the same reasons. In the corporate world, a high performing Achiever is seen as the pinnacle of an executive's leadership capacity. By altering the term to Achievist, the stage development lens can be encountered and interpreted more objectively.

Factors Related to Later Stage Development

Later stages have been correlated with increased leadership effectiveness. Evidence indicates that executives at later stages with more complex meaning-making systems are more effective leaders (Eigel, 1998; Eigel & Kuhnert, 2005; Harris & Kuhnert, 2008; Strang & Kuhnert, 2009; Rooke & Torbert, 2005). A deeper appreciation of themselves, their interactions and strategic context, in other words intrapersonal, interpersonal, systems and cognitive skills and capabilities, help leaders to be more effective. Furthermore, the capacity to lead and sustain transformative organisation-wide change, emerges at Synergist (Rooke & Torbert, 1998).

The Pace of Later Stage Development

The two later stages of development with which this research study was primarily concerned are the first two postconventional stages of Catalyst and Synergist. While the proportion of the executive population at Catalyst has been increasing by 11% in each of the last two decades to rise to a total estimate of 33%, the proportion of Synergists amongst the executive population – has stalled at 8% increasing by just 1% in each of the last two decades (Cook-Greuter, 1999; PwC Report, 2015). Half of senior leaders believe that their investment in leadership development does not build critical capabilities despite the $164b annual investment in leadership development in the United States alone (Beer et al, 2016; Moldoveanu & Narayandas, 2019). There appears to be a deficiency in current leadership development methodologies to enable vertical development to Synergist.

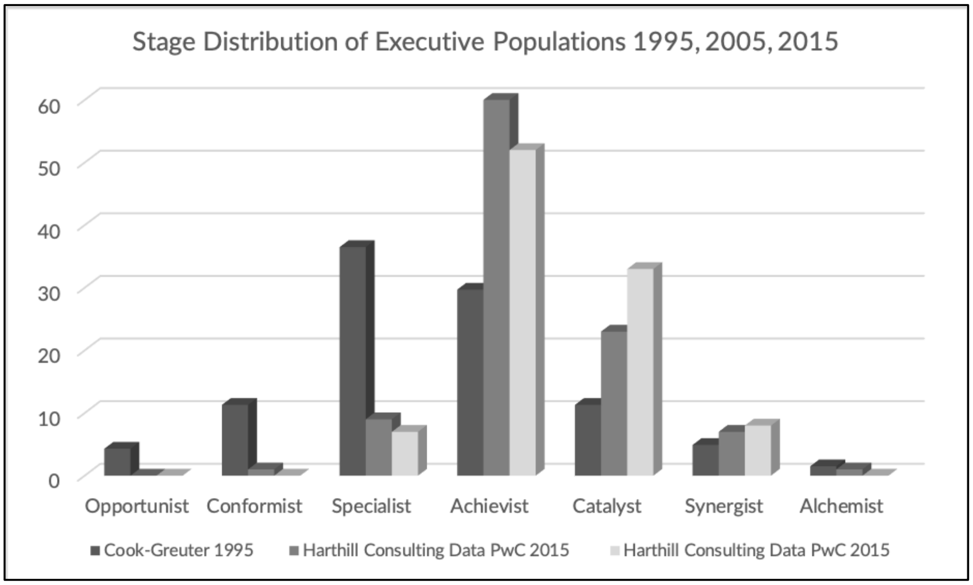


Figure 1. The Distribution of Executives across the Stages of Development.

Torbert (personal communication, March 11, 2015) suggested that vertical development from Achievist to Synergist would take as many as six years with a Synergist coach. His view was inevitably based on an early study of MBA graduates, where Torbert & Fisher (1992) found that the six who participated in a reflective action inquiry group every 3 weeks over 5 years had shifted a full stage to Synergist in contrast to the other nine graduates who only developed their leadership capacity by 5% during that time. Rooke & Torbert (2005) further advised that, in addition to one individual making the shift from Specialist to Synergist over a period of three years, "[w]e have had only two other instances in which a leader has transformed [two stages] in less than four years" (p. 73).

Vincent (2015) undertook a more recent study of 335 adults with an average age of 40 who were undertaking a 12-month Community Leadership Program (CLP). She found that the enhanced 25+ day CLPs including psychosocially disequilibrating events, were more effective in triggering later stage vertical development than the standard CLPs. Of those who attended the enhanced CLPs, 29% (46/157) shifted from Achievist to Catalyst, and 23% (9/40) from Catalyst to Synergist. In total, 28% (55/197) shifted one stage to one of these two later stages after attending the one-year intensive and enhanced leadership program.

Brown (2014) suggests that executive leadership programs based on integral theory focused more explicitly on expediting vertical development to transpersonal stages, such as Pacific Integral's Generating Transformative Change Program, are significantly more effective. "Typically, it takes five years for a leader to shift a full action logic, or developmental stage, if they shift at all. Leaders in these programs [MetaIntegral Assoc, Pacific Integral, JFK University] shifted as much as an entire stage or two in vertical learning programs lasting 1–2 years." (Brown, 2014, p. 25) Pacific Integral programs involve four 5-day residential retreats over a period of nine months.

In summary, vertical development to the later stages of Catalyst and Synergist is probable for participants in a peer group, potentially inclusive of later stages, undertaking developmental action inquiry over a period of 5 years. Based on Vincent's (2015) research, perhaps a quarter of participants could be expected to shift to later stages after attending a 25+ day 12-month comprehensive leadership program that includes psychosocially disorientating experiences (Manners & Durkin, 2000) yet is not explicitly designed to enable vertical development. However, all participants attending 20-day 9-month Pacific Integral programs which are explicitly designed to foster vertical development to indeed transpersonal stages, often shift one, and sometimes two, stages during this short time.

Factors Driving Later Stage Development

There are a number of factors that may contribute to enabling later stage vertical development. Torbert & Fisher's (1992) study of MBA graduates described above, suggests that reflective action inquiry with peers is useful. Laloux (2014), famed for his work in organisational evolution, suggests that creating the opportunity for self-expression, revelation, feedback and reflection amidst diverse perspectives including *later stage peers* is conducive to later stage leadership development. Indeed, facilitators of the highly effective Pacific Integral Leadership Programs are renowned for their transpersonal perspective.

Another key factor included in Vincent's (2015) study above, was the notion of disorientating dilemmas first espoused by Mezirow (2003) as having the power to invite transformative learning. Piaget (1954) suggested that disorientating dilemmas demanded an adaptation of the meaning-making frame to make sense of new perplexing information, signifying vertical learning beyond one's current perspective. He called this an accommodation process. This was in contrast to new data that could be assimilated i.e. understood within one's current frame of reference, suggesting horizontal learning within the person's current stage of development (Kegan, 1982).

In their research study, Manners & Durkin (2000) found that having a personal disposition that was curious and open to attracting personally salient life experiences that were emotionally disorientating, was likely to generate stage development to Achievist. This was based on a brief research study where 76% (16/21) of adult participants advanced one stage from Specialist to Achievist following a 10-week group program of one 90-minute workshop per week. Vincent's (2015) study suggests that 29% of participants might develop to later stages as a result of engineering this type of psychosocially challenging intervention.

Geoff Fitch, Founder of Pacific Integral, believes that the intimate collective holding space co-created during Integral Leadership Retreats is significant in liberating later stage development (Ch 4, Gunnlaugson & Brabant, 2016). Perhaps it is not the disorientating dilemmas or "heat experiences" (Petrie, 2015) themselves that enable later stage development, but the deeper inquiry into interpreting the experience of the participants. A transpersonal facilitator has the power to hold a psychologically safe, supportive and sacred space for this inquiry and the insight to invoke deeper meaning-making for the participants.

The exploration and integration of identity is thought to facilitate vertical development. Petriglieri et al. (2011) found that revisiting life stories and navigating existential puzzlement with the support of individual psychotherapeutic counselling was both in high demand and highly valued by MBA students. Pfaffenberger (2011), on comparing the written narratives and interview transcripts concerning the growth process of 22 postconventional participants with those of a control group of six conventional participants, also found that interiority, alongside intentionality and complexity, was one of three key themes that distinguished later stages.

'Interiority' reflected taking a personal inquiry into one's inner awareness. The second theme, intentionality, referred to the commitment to prioritise personal growth despite the discomfort and increasing sensitivity. Interiority and intentionality appear to be developmental drivers associated with shaping a coherent inner identity and the intentional resolution of challenging tensions and paradoxes at a deeper level. Quatro et al (2007) also advise that a person develops to later stages by integrating the analytical, conceptual, emotional and spiritual dimensions of their holistic self.

The exploration of identity is connected to shadow work. Kilburg (2004) described shadow as "unconscious material in the form of past experience, emotional responses, defensive reactions, underlying and unresolved conflicts, and dysfunctional patterns of thinking and behaving [that] can contribute to poor leadership and consequently to decreased organisational effectiveness" (p. 249). By bringing these elements into conscious awareness, a person can more easily adjust otherwise disruptive behaviours and alleviate significant distress and anxiety, leading to enhanced wellbeing (Kilburg, 2004). Shadow work is also thought to advance a person's meaning-making patterns to realise later stage development (Kaiser & Kaplan, 2006).

Other ways of expanding meaning-making are: the integration of polarities (Sharma & Cook-Greuter, 2012); the resolution of tension between espoused and lived values (Rooke & Torbert, 2005); consciously working with an open mind, open heart and open will while suspending voices of judgement, cynicism and fear (Scharmer, 2007); mindfulness, meditation, contemplative and reflective practices that serve to deepen inner awareness.

A further aspect of vertical development is that a person can generally only develop up to the level of evolution supported by the organisation they are a part of. For instance, the competitive, high-performance structure and culture of an orange organisation would largely contain development to the associated stage of Achievist. Innovative organisational practices at later stages of development i.e. green and teal, suggest that the evolutionary level of the organisation is a highly influential factor in either prohibiting or encouraging later stage development (Hamel, 2007; Laloux, 2014). Kegan et al (2014) recommend prioritising deliberately developmental practices within organisations to stimulate vertical development.

In summary, vertical development can be accelerated by regular reflective action inquiry, especially with later stage peers, and by making deeper meaning of disorientating experiences at integral retreats with transpersonal facilitators. Intentionally taking a holistic view of all dimensions in one's inner world, potentially with the help of a psychotherapist, can also lead to the development of a more integrated identity. Working with values, polarities and mindfulness in deliberately developmental, contemplative ways may stimulate later stage development, and working in conventional organisations is thought to inhibit development while engaging in green to teal organisations stimulates associated personal development to the equivalent evolutionary level.

Quantitative Findings in Later Stage Development

The Motives that Led to the Research

There were a number of interconnecting factors that led to the research project. I had been working as an executive coach for about three years. While most clients appeared to gain substantial value from the coaching, I wondered if I was actually making a real difference. Was my coaching genuinely effective as well as providing clients with a purposeful and valuable time to reflect, rewind and reframe? The outcomes of my work as an executive leader of People and Culture and business transformations, had been more explicit and tangible.

I had become aware of stage leadership development by undertaking a workshop with Susanne Cook-Greuter in 2010. I discovered that I was operating as a Synergist with 72% of sentence completions at post-conventional levels and 42% at Synergist and Alchemist. I also discovered that only a small proportion of executives operate as later stage leaders, particularly at Synergist when they become able to lead and sustain organisational transformations (Rooke & Torbert, 1998). At that time, only 10% of leaders operated from Catalyst and 5% at Synergist and beyond (Rooke & Torbert, 2005). I felt that the world was urgently in need of transformation to become more sustainable, healthy and equitable, and therefore in urgent need of more leaders operating from the Synergist perspective.

I enrolled in a PhD and three years later began my research project. I was involved as a management assessment consultant and executive coach in the Leadership Development Program for the 400 most senior executives in the New South Wales (NSW) public sector. Following an initial plenary assessment, debriefing and short coaching process, they were individually funded to undertake a psychological assessment followed by more coaching. I took the opportunity to launch my research study.

My research question morphed over time to become:

> How might Executive Coaching with a Later Stage Executive Coach at Synergist enable vertical leadership development for strategic leaders predominantly at the conventional stage of Achievist to the less commonly held later postconventional stages of Catalyst and Synergist?

Setting up the Multiple Case Study Research

I invited 25 strategic leaders with divisional, functional or regional responsibilities in the NSW public sector to undertake the highly validated stage assessment instrument, Cook-Greuter's Mature Adult Profile (MAP) (Cohn & Westenberg, 2004; Loevinger & Wessler, 1970). This requires a person to independently complete 36 sentence prompts. In this way they project their thoughts and ideas on a wide range of life and work concerns. Susanne Cook-Greuter herself kindly agreed to score the assessments.

Of the 25 strategic leaders invited to take the assessment, 12 scored with more than 80% of their profile up to and including Achievist. To focus the research on the shift from Achievist to later stages, these 12 were invited to participate in the research study. Of the 12 invited, nine agreed. They formed an initial purposive sample of conventional strategic leaders. Three participants were added to the project later, one more from the public sector making a total of 10 (83%) and two from the financial services sector (17%).

The average age of the 12 participants was 50, ranging from 36 to 56. There were seven men and five women. They were all graduates, and six had postgraduate degrees including one doctorate. Their roles included Deputy/Assistant Secretary/Commissioner, C-suite, Head of Agency, Executive Director, Program and Operations Directors. They worked across the agriculture, education, environment, financial services, health, justice, premier's office, rescue services, trade and industry, and transport sectors.

The proportion of their average aggregate stages profile up to and including Achievist at the beginning of the research project was 88%. Thus, their average aggregate later stage profile was just 12%. They committed to attending a 12-month coaching program. They also agreed to an explicit intention to realise later stage leadership development. They were not involved in any other organised leadership development activities.

The 90-min coaching meetings were set up for the same time and day each month over the ensuing 12-month period. The participants could reschedule meetings during and beyond the 12-month period at their discretion. During the year, they attended an average of eight (8.4) coaching sessions, ranging from five to 12 each. The three who attended fewer coaching meetings tended to meet bi-monthly instead.

My coaching preparation consisted of revising past coaching notes, meditating briefly to become centred, calm, caring and present, ensuring that there was water and mint tea ready, and setting intentions to co-create an insightful and valuable coaching dialogue for the coachee. All of the meetings took place in person in large corporate meeting rooms on the upper floors of centrally located buildings with panoramic views over Sydney parkland and harbour. A whiteboard stretched across a wall was used regularly to capture new ideas and explain emergent concepts to facilitate development and understanding.

My coaching approach was non-prescriptive and unstructured. I had undertaken little formal coaching qualifications at that time and simply drew on my experience, expertise and Synergist perspective of life and business to inquire, respond and generate an uplifting transformative dialogue on whatever was raised by the coachee. I also intervened purposefully if I encountered a blind spot in the coachee's reflections or general chit-chat. In offering feedback, one coachee remarked:

> I remember one day I began a coaching session by describing how irritated I had been by a hygienist cleaning my teeth. … I just wanted to vent and remove this experience from my state of mind. Little did I know that Antoinette would turn this into a teaching moment for me. She provided a life-changing reflection back to me – did I want to be reactive to situations? She told me that my reaction was as much about me as it was about her. Did I want to be an irritable or irritated person, or did I want to be a different type of person in the world? I did not believe it was possible to change my personality, and then I realised I could. I wasn't that type of person; I could be whoever I wanted to be. I've never forgotten that moment.

Measured Outcomes Post the Coaching Program

After 12 months, nine of the participants undertook a second MAP assessment. These assessments were sent to Cook-Greuter anonymously without any identifying data for her second assessment. Of the additional three participants, one undertook a Global Leadership Profile (GLP) assessment and two others undertook a STAGES Profile assessment. These alternative stage assessments followed my studies with Bill Torbert, creator of the Global Leadership Profile, and Terri O'Fallon, creator of the STAGES Profile. The scoring systems of these three assessments have been shown to be highly correlated, particularly up to Synergist (O'Fallon et al, 2020; Torbert & Livne-Tarandach, 2009). By 2018 my stages assessment was at 5.5 (STAGES) with 100% of my profile at Synergist and beyond. The coaching programs with the three additional participants took place from 2016-2018.

It was found that ten (83%) of the participants had shifted a full stage, eight from Achievist to Catalyst. One participant shifted from Specialist to Achievist and one participant shifted from Catalyst to Synergist. The two remaining participants (17%) shifted two stages from Achievist through to Synergist.

Table 2. Pre- and Post-Coaching Stage Assessments.

	Total Weighted Score (TWS)			Total Protocol Rating Primary Stage		% Profile at Postconventional		
Participants	Pre-	Post-	Change	Pre-	Post-	Pre-	Post-	Change
A	242	278	+36	Achievist	Synergist	19%	64%	+45%
B	244	265	+21	Achievist	Catalyst	6%	36%	+30%
C	245	293	+48	Achievist	Synergist	11%	81%	+70%
D	232	266	+34	Achievist	Catalyst	6%	50%	+44%
E	233	260	+27	Achievist	Catalyst	3%	31%	+28%
F	212	241	+29	Specialist	Achievist	0%	6%	+6%
G	242	265	+23	Achievist	Catalyst	0%	39%	+39%
H	247	261	+14	Achievist	Catalyst	11%	31%	+20%
I	244	271	+27	Achievist	Catalyst	17%	50%	+33%
J	231	261	+30	Achievist	Catalyst	6%	37%	+31%
K	244	266	+22	Achievist	Catalyst	17%	39%	+22%
L	265	298	+33	Catalyst	Synergist	47%	93%	+47%
MEAN	240	269	+29	T = 9.7E-08 t = 1.7959	$p < 0.0001$	Aggregate Profile Shift		
Std Dev	12.55	15.21	8.7			12%	46%	+34%

The mean of the difference in the before and after scores was 28.7, approximately the ambit of a full stage. The difference in the before and after scores ranged from 14 to 48 points. There were no outliers (Tukey Fence). The standard deviation of the difference was 8.7. A matched sample paired t-test showed that there was a highly significant statistical difference between the before and after Total Weighted Scores (TWSs). The R^2 of this shift was 0.519 with a single tail p-value of 0.00001 at a 95% confidence interval.

In summary, all participants shifted a full stage (100%). Two navigated a double shift from Achievist to Synergist (17%). These are significant findings from a practical perspective. An average of eight 90-minute coaching sessions or 12 hours (2-days) of executive coaching spread across a year with a later stage executive coach at Synergist, accomplished the degree of stage shift that had otherwise only been known to have taken place following 20-day intensive group Integral Leadership Programs.

Three of the first group of participants agreed to undertake a third GLP assessment three years later. They were all assessed at Synergist. They increased their average aggregate later stage profile by 72% from 16% in Year 0, to 65% in Year 1 and onto 88% in Year 4. This indicated that the earlier results achieved were sustainable and that the coaching could activate the integration from Catalyst to Synergist.

The Hedges g score showed that the number of coaching sessions undertaken by the participants during the research project, had no significant effect on the scope of the shift in each participant's profile. Some coaching sessions were also taken prior to the research project, and those that undertook the third assessment had continued with an average of six coaching sessions following the project. The Hedges g score showed that the total number of coaching sessions undertaken had no significant effect on the results. The average number of coaching sessions undertaken by those who shifted two stages in one year from Achievist to Synergist was eight.

The Structural Nature of the Stage Shift

The structural nature of the average aggregate profile shift was curious. It was calculated based on the average percentage of sentence completions at each stage of development. In the initial shift predominantly from Achievist to Catalyst, the proportion of sentence completions at Achievist remained relatively stable, while the neighbouring stages increased and decreased around this centre of gravity. It was curious because I had anticipated more of an incremental increase across all developing stages and a similar decrease across all earlier stages. I wondered if this might point to a new insight, at least for me as an experienced practitioner, in the nature of vertical development. To explore this further, notwithstanding the tiny sample size for this type of analysis, I looked at the data only for those shifting from Achievist to Catalyst, and the data only for those who had shifted onto Synergist.

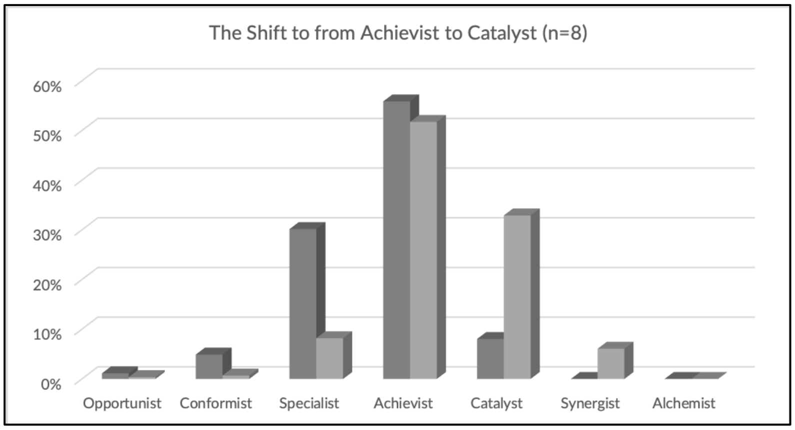

Figure 2. The Structural Nature of the Stage Shift to Catalyst.

In the shift to Catalyst (n=8), the proportion of sentence completions at the previous slight leading edge of Catalyst increased significantly from 8% to 33% (+25%) to become their primary stage. The previous primary stage of Achievist stayed largely stable (-4%) and defaulted to secondary due to the growth in their leading edge at Catalyst. Simultaneously, the previous secondary stage and trailing edge declined substantially (-27%), leaving their previous secondary stage at Specialist as their new trailing edge. They had a new leading edge at Synergist (+6%).

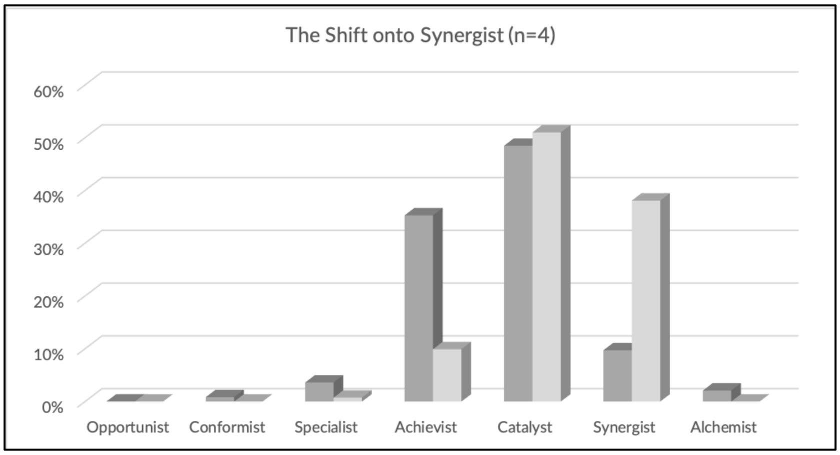

Figure 3. The Structural Nature of the Stage Shift onto Synergist.

Similarly, in the shift onto Synergist (n=4), the new primary stage of Catalyst remained relatively stable increasing by only 3%. The percentage of sentence completions at their leading edge of Synergist flourished by 28% while their profile at Achievist diminished by 25% to become their new trailing edge. The profile changes surrounded, rather than affected, their previous new primary stage at Catalyst.

These indicative findings on the structure of stage development suggest that cultivating the next person perspective at their leading edge while eliminating or reducing their regression to earlier stages by undertaking shadow resolution work related to them, is the key to later stage vertical development. The current integrated stage of development is sustained during the process of vertical growth until the next integrated stage of development has been experimented with, understood and become embodied. This way a person can continue to rely on their primary way of making sense of their world while actively nurturing vertical development. It appears that it is not until both steps in the individuation/integration process (Cook-Greuter, 1999) are completed and the person has matured into a new integrated stage of development, that the previous primary stage of integration is released.

This supports O'Fallon's (2011) revelations of the structure of stage development in the Inner and Outer Zones. During the x.0 individuation stage of development in one's inner world, the previous (x-1).5 stage in the outer world continues to prevail. The findings add credence to my observations from my coaching experience in vertical development to Synergist, that a person only arrives at this stage once they can confidently express and demonstrate their personal transformation by leading transformation of their organisation.

This insight perhaps partly explains the fact that while executive leaders have been increasing to the stage of Catalyst by 11% in each of the last two decades, the transformation to Synergist has stalled (PwC, 2015). These postconventional executive leaders would appear to still have their centre of gravity, albeit their secondary stage, at Achievist. It seems that unless developmental interventions deliberately encourage active experimentation in the outer zone of integration at Synergist while intentionally releasing the hold of the Achievist and earlier stages through shadow work, vertical development to Synergist cannot ensue.

Summary of Quantitative Research Findings in Later Stage Development

1. The motives for the research project were to explore my effectiveness as a coach and the potential for executive coaching with a later stage executive coach to expedite later stage vertical development to Catalyst and Synergist.

2. Twelve strategic leaders with substantial divisional responsibilities, seven men and five women with an average age of 50, half graduate and half postgraduates, participated in the research. They started out with 88% of their average aggregate profile up to and including Achievist.

3. They undertook an average of 8.4 (range of 5-12) 90-min (12.6 hours) face-to-face one-to-one coaching sessions with a Synergist coach, monthly or bi-monthly over the course of a year.

4. Ten (83%) of the participants shifted a single stage, eight from Achievist to Catalyst; one from Specialist to Achievist and one from Catalyst to Synergist. Two (17%) shifted two stages from Achievist to Synergist.

5. The mean of the difference in the before and after TWSs was 28.7 (range of 14-48) and the standard deviation of the difference was 8.7.

6. A paired t-test showed that there was a highly significant statistical difference between the before and after TWSs. The R^2 of the shift was 0.519 with a single tail p-value of 0.00001 at a 95% CI.

7. Three of the participants undertook a third stage assessment three years after the second and were all assessed at Synergist. They increased their average aggregate later stage profile by 72% from 16% in year 0 to 65% in year 1 and onto 88% in year 4.

8. In the transition to the next stage, the primary stage remained stable. The leading edge grew to become their primary stage and their secondary stage and trailing edges dropped away.

9. The research findings suggest that a person's Centre of Gravity is better understood as being in their latest integrated stage, primary or secondary, rather than in their primary stage if it is in an individuation stage.

The Drivers Leading to Later Stage Development

The Matrix of 8 Key Coaching Interventions

The coaching conversation notes from the first nine participants comprised >75,000 words. They were compiled into one large word document. First, they were analysed using Leximancer's online content analysis tool. Two overarching themes emerged: People and Strategic, together with eight other topics. These were crystallised into categories and the conversations within the transcripts were coded accordingly. The coded conversations were then captured in a large excel spreadsheet by category (row) and coachee (column).

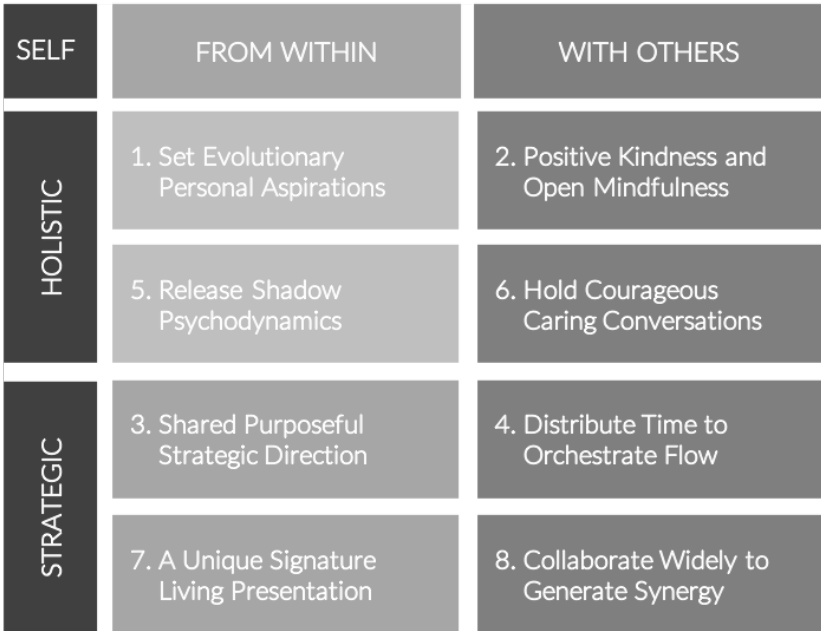
After many recurring cycles of reflection and analysis on the substance and nature of the data over a period of two to three years using inductive thematic analysis (Boyatzis, 1998), it was found that the two key themes held: Strategic and Holistic Leadership Development. Strategic coaching conversations related to the coachees' roles as organisational business leaders. They focused on the Collective. Holistic coaching conversations concerned them more intimately as individual people navigating life, both at work and at home. They focused on the Self.

After further consideration and following study of the STAGES model (O'Fallon, 2011), I realised that some of the subcategories related to inner work such as exploring identity, developing self-awareness, diving deep to understand and resolve shadow, and articulating aspirational intent and strategic direction. This type of work seemed to be more closely associated with the Inner Zone work at the Reciprocal stage of Catalyst, potentially also reaching towards the aspirational intent of Constructivist. The other subcategories were concerned with active application, engagement with others and the implementation of what had been learnt, reminding me of the Outer Zone work at the Interpenetration stage of Synergist.

As a result of this iterative process of reflection, sorting, analysing and resorting, eight different coaching interventions were identified. These eight drivers formed a matrix. Four drivers were Strategic, and four Holistic. Four related to inner work and four to outer work with others.

It was also found that the drivers were introduced in a similar order across all the case studies. As time went on, the coaching became more personally and interpersonally challenging, as well as more expansive in terms of proactively engaging larger groups of people beyond their immediate role. Here is the StageSHIFT Matrix of Later Stage Vertical Development showing the order from

1 to 8 that enabled the participants to integrate the 4th person perspective from Achievist to Catalyst and onto Synergist.



SELF	FROM WITHIN	WITH OTHERS
HOLISTIC	1. Set Evolutionary Personal Aspirations	2. Positive Kindness and Open Mindfulness
	5. Release Shadow Psychodynamics	6. Hold Courageous Caring Conversations
STRATEGIC	3. Shared Purposeful Strategic Direction	4. Distribute Time to Orchestrate Flow
	7. A Unique Signature Living Presentation	8. Collaborate Widely to Generate Synergy

Figure 4. The StageSHIFT Drivers of Later Stage Development.

Driver 1: Set Inspiring Evolutionary Personal Aspirations

Coaching programs often begin with setting developmental goals. My preference was to set personal leadership aspirations in the form of a declaration. Each coachee articulated the type of leader they would like to become and completed their statement with their highest intrinsic purpose. This took time to develop and refine, and invariably involved developing the coachee's self-awareness of their unique strengths, passions, potential, purpose and personal aspirations. This is similar to the first step in the Boyatzis (2008) Intentional Change Theory although I would add that a later stage Synergist/Constructivist perspective tends to uplift coachees' aspirations.

The rationale was to attract the very experiences that would both challenge and bestow the person with the opportunities to realise their highest potential – that was my intrinsic purpose. By setting a strong guiding affirmation, I believed that the power of the mind, heart and spirit would set up the opportunities and obstacles in life's pathway to fulfil this declared intention. This was based on the writings of philosophers such as the following quote by Indian sage Patanjali, and to some extent, reflected in my own life experience.

When you are inspired by some great purpose, some extraordinary project, all your thoughts break their bonds; your mind transcends limitations; your consciousness expands in every direction; and you find yourself in a great new and wonderful world. Dormant forces, faculties and talents become alive and you discover yourself to be a greater person by far than you ever dreamed yourself to be.

Driver 2: Sustain a Positive, Kind, Open and Compassionate Mind

A key element that arose repeatedly across all the case studies was the common criticism and judgement of others. Calling other people “idiots” and “useless”, or otherwise venting about their annoying qualities is prevalent amongst people at the stages of the defensive Specialist and competitive Achievist. In integral speak, this element was about ‘showing up’ in a positive, kind and balanced state to minimise and indeed eliminate any negative ripple effect on other people.

This Driver incorporated positive psychology (Seligman, 2011), the use of only positive language, deletion of negative thoughts, heart-based reflective practices, mindful reprogramming and the development of a growth mindset and new wellbeing habits such as meditation and journaling. The Interpenetrative nature of the Synergist in the STAGES Model also fuelled this driver. By taking on board that all vengeful criticism was really transference, the coachees learned to lift their level of conscious self-awareness on an everyday basis.

One of the coachees shared their experience of this driver as follows:

> I was always intolerant of fools and cranky, idiotic people behaving badly ... Realising that whatever happens in their life, they are trying to do the best they can - maybe a bit more understanding from me rather than creating relationship issues with them would be better ... Huge shift ... Biggest shift of all!

Driver 3: Engage Everyone in Setting Shared Purposeful Strategic Direction

This was the first strategic driver focused on generating transformative leadership by each coachee of their division as a Collective. The timing was perfect to set strategic direction for the years ahead as the coaching programs began at the beginning of the financial year. The nature and structure of setting strategic direction involved many empowering models and liberating frameworks I had used effectively as an Organisation Development consultant. They had lifted people engagement by 30% in six months and had the power to lift an organisation to green.

This driver included working with each coachee on setting a purpose, vision, set of values, strategic outcomes, annual themes, strategic shifts in culture and performance, and key strategic initiatives to set up a second operating networked system as recommended by Kotter (2014) to accelerate business evolution and innovation. The coachees were also coached on how to effectively engage and empower their people in the process of generating and agreeing to a Strategic Business Charter and cascading this throughout their division.

Eleven of the 12 coachees implemented this driver and many found the process highly engaging and rewarding. They were proud of their final A3 masterpieces setting out the ‘big picture’ and were recognised by their managers and government Ministers for their transformative views of the future. It is interesting to note that the two coachees who did the most work co-creating, implementing and continuously engaging their people on the Strategic Charter, moved most rapidly to Synergist. This driver was highly empowering for their teams who could then be held accountable for achieving the goals freeing the coachees to be more strategic leaders. A coachee explained:

> [My purpose is] to set higher order strategic outcomes . . . and advance a strategic, scientifically based perspective along with effective and accountable probing governance with greater integrity . . . in such a way that everyone feels engaged, identifying with and owning a longer term strategic vision so that the return on the investment for the Australian public and industry sponsors generates tangible, breakthrough solutions that create a healthier environment for life and future generations.

Driver 4: Distribute Time to Generate a Dynamic Flow

This driver operationalised Driver 3. A Dynamic Operating Rhythm was created during coaching meetings to reduce time pressures, long hours and stress levels. Rather than managing time, the focus was on optimising energy levels and brain wave activity and distributing time to allocate the flow of the important streams of work that a strategic leader was responsible for e.g. strategic direction, oversight of key initiatives, stakeholder engagement, people and culture, and overall governance in relation to the effectiveness of the business model.

It included an iterative cycle of meetings for their teams, direct reports, projects and stakeholders, and liberating meeting agendas to enable full engagement, embed accountability and encourage collaboration. The weeks of the month, days of the week and the hours of the day were orchestrated 18-months ahead to optimise strategic performance and governance, and individual productivity, creativity and wellbeing in accordance with a person’s natural ultradian rhythm and brain processing agility.

This driver confronted many typical organisational norms. One of the most pervasive was the ever-changing meeting schedules of senior executives. The Dynamic Operating Rhythm regulated this and ensured attention was given to their own strategic priorities and people first and foremost, while freeing them to then engage more strategically externally. It conserved their conscious energy otherwise depleted by navigating a changing schedule day-by-day and enabled the coachees to move into a more emergent flow state.

Coachees were able to shift from being reactive to proactive, from the detail to the engagement:

> Setup time on Monday is proving to be very valuable . . . Feeling of being more effective and more productive. … I now have time to synthesise; what’s my position going to be in the next meeting? ... Really present, not absent. Articulating point of view on Exec Team. Now paying attention to the human dynamics, interesting drama playing out in front of me.

Driver 5: Explore Psychodynamics to Heal Shadow & Eliminate Triggers

This is the first of the second set of holistic drivers focused on deepening self-awareness and resolving shadow (Kilburg, 2004). Emotional triggers were seen as a signalling system for healing. Rather than focus on self-regulation in terms of emotional intelligence (Goleman, 1995), the emotion that was being triggered was sourced back to the original similar psychodynamic situation as a child and dealt with there. This transformative approach tunes into spiritual intelligence.

The coach had learned that by inquiring into her own emotional triggers and traumas, navigating a cognitive process to understand the psychodynamics and a heart-based process to forgive all involved in the situation while embracing the inner child, enabled situations to be healed at source. This process eliminated both the reoccurrence of similar psychodynamics and the voices in the mind that were associated with the trauma or drama in the past. In the coach's experience, when this 'GRIEF' process was applied to all emotionally charged events, regrets, resentments, prejudices and grievances were released, one's identity became integrated and the mind emptied to become calm and clear. This shadow resolution process released mindsets associated with earlier stages.

The underlying principle that supported this approach was again the concept of Interpenetration in the STAGES Model (O'Fallon, 2011). In my words albeit not necessarily original expression: Life doesn't just happen to us, it happens through us, as us. The self and life are interpenetrative. The healing of egoic wounds from the past also resonated with the shadow crash orientation of the STAGES Model. These wounds inhibited a more robust construction of character at earlier stages. If triggered, a person generally reacts or suppresses the emotional charge. Either avenue is unproductive. However, if the shadow crash is illuminated and resolved, character foundations can be rebuilt in a more stable fashion to support ongoing later stage development.

"How can I be substantial if I do not cast a shadow? I must have a dark side if I am to be whole." (Jung, 1931)

Driver 6: Sustain Standards with Courageous Caring Conversations

This final holistic coaching intervention involved demonstrating courageous and authentic integrity in a gracious, compassionate way. This coaching driver was the most common across all case studies. All coachees felt intimidated, threatened and/or distressed due to corporate politics or others' abusive behaviour during the 12-month coaching program. The fear of speaking out in the face of powerful authority figures and employment risk, is associated with the reptilian amygdala response of fight, flight or freeze, and the emotional limbic brain.

Coaching sessions were an ideal opportunity to gain perspective and discern the standards, boundaries and priorities that were potentially out of synch in relation to the mutually respectful collaborative power that is demonstrated at Synergist. The coach invited and helped coachees to script an appropriate TIP – Truth-Implications-Point - conversation that could then be held in the workplace to address difficult situations.

The capacity to express oneself truthfully, openly and assertively with vulnerability and grace, while *holding* the other person's self-esteem and feelings in mind, rather than simply *having* the conversation, is relatively rare. To be able to do so in the moment that it is called for, is even rarer still. Holding these types of conversations left a lasting impression on many of the coachees. One said:

The things that I've been working on, me tuning into me, has really allowed me not to baulk at these situations. I can have an open conversation with any one of my team members, team members have been in tears because they are learning things that are fundamental to who they are, gaining in self-awareness ... It allows me to help others become more authentic, authenticity breeds authenticity ... Me growing is causing or generating their growth! because I'm empowering the team to grow.

Driver 7: Articulate an Inspiring Unique Living Signature Presentation

This is the third strategic driver. It arose in response to the many demands on the coachees to make presentations at Conference events, special gatherings such as farewells, important family events, invitations from Universities to honour graduates or to mark a new strategic direction for their industry sponsors and community interest groups. Rather than be descriptive or playing it safe, the coachees were invited to create an authentic, transformative, inspiring and compelling signature presentation for their audience.

It was ‘unique and living’ in that the coachee was the centre of their presentation. It concerned their purpose, their passion and their aspirations. It was intended to be continuously enhanced with every presentation opportunity so that it could evolve and develop new momentum and influence with each outing. The driver evolved to incorporate 12 P’s which became the focus for open questions during coaching sessions to provide the coachee with the opportunity to share their greatest aspirations and deepest sense of what mattered most to them in a very human yet strategic way.

I believe this driver leans into Constructivist leadership capacity of the fifth person perspective. It was exciting to see new presentation opportunities arise as coachees developed and built on their signature presentations. The expression of one’s authentic voice in a courageous. committed and convincing manner with eloquence and presence is an outstanding hallmark of a leader at Synergist. Coachees were enthralled:

> Speaking can be a bit of a struggle, 35 on Friday, 150 next week. ... Once in the groove, speaking from the heart ... Very passionate ... So exciting ... Envisaging what is going to be happening in 10 years’ time today. ... I’ve been advised that I was the top speaker at the conference.

Driver 8: Collaborate Widely with Stakeholders to Generate Synergy

The final driver was focused on proactive engagement first with internal stakeholders and then with external stakeholders taking a complex adaptive systems interventionist approach (Cavanagh, 2013). The coachees who had responsibility for resolving conflict and collaborating with a variety of external stakeholders or had accountability for new business development, valued discovering how to gain in influence, market presence and proactively win the engagement and support of others in their communities and industry.

This driver involved stakeholder relationship mapping and taking a strategic approach to building relationships with others individually and in groups in a purposeful campaign-like manner. Synergists are able to hold the space for diverse, disconnected, conflicting stakeholders to release their anxieties and trust in the process of dialogue to realise mutually beneficial outcomes. This type of interaction had the potential to lead to integration. Coachees enjoyed the results that flowed from building flourishing partnerships and co-creating transformative outcomes.

> My approach is successful, meeting every timeframe to the day. Tear down the transactional framework, get away from the contract to the relationship, it's unheard of to hit deadlines like this as consistently as this. Met every single deliverable on time every time, 15 June for X, 17 August for Y, and with really strong partnership relationships with suppliers and stakeholders ... Our key supplier relationship has evolved into a real partnership.

Summary of the Drivers Leading to Later Stage Development

1. There are eight key drivers of later stage development. They are:
    i. Setting inspiring evolutionary personal aspirations
    ii. Sustaining a positive, kind, open and compassionate mind
    iii. Engaging everyone in setting shared purposeful strategic direction
    iv. Distributing time to generate an orchestrated yet organic flow
    v. Exploring psychodynamics to heal shadow and eliminate triggers
    vi. Sustaining standards with courageous caring conversations
    vii. Articulating an inspiring unique living signature presentation
    viii. Collaborating widely with stakeholders to generate synergy

2. They form a matrix of which four (3, 4, 7, 8) are related to strategic business development and four (1, 2, 5, 6) to personal holistic development.

3. Two within each set of four drivers are related to inner awareness and aspirational intent (odd numbers: individuation), and two to application, engagement and implementation (even numbers: integration).

4. The coaching included explicit mentoring in vertical organisational development to transcend the amber and orange conventional norms and generate new empowering and collaborative norms.

5. Holistic stage development combined realising and embodying one's higher aspirational self while releasing embedded shadow and reactive patterns that otherwise stall one's vertical development.

The Dynamics of Later Stage Development

The Blend of Strategic Holistic Executive Coaching

An executive leader tends to feel constrained by their list of role responsibilities, their levels of delegation, their accountability for budgets and deadlines, and their need to comply with the conventional norms that prevail in amber and orange hierarchical organisations. By reshaping the strategic context and operating system for their organisation in empowering uplifting ways, each participant was challenged to step up in vertical development.

While the coaching was in response to the coachees' need to create a strategic plan, the coaching response was of an evolutionary order of later stage vertical development. The new strategic context broke through Specialist and Achievist paradigms of excellence and performance, to create a new 4th-person-perspective playing field where higher aspirations, authentic engagement, radical accountability and emergent collaboration were integrated into the strategic planning, team engagement and performance governance processes and practices.

In terms of the holistic coaching, the value of setting aspirational intent beyond developmental goals to cultivate the person's evolution even beyond their leading edge seemed to stimulate their later stage evolution. The deeper and more intimate focus on resolving and healing shadow to release negative and punitive mindsets that related to earlier life events when at earlier stages, went well beyond the more standard coaching approaches of self-regulation and the development of emotional intelligence. In combination, setting aspirations, cultivating self and resolving shadow expedited later stage development.

This concept of vertical stage development was depicted to the coachees as a Spectrum Stage Shift in their operating system from a Centre of Gravity at Achievist to a Centre of Gravity at Synergist[2]. The Figure-8s, illustrated in figure 5, present both the overlap and quantum shift in the spectrum of stages a person with a mature person perspective profiles with at these stages. While anchored at Achievist, they could still develop Catalyst leadership agility as their primary stage, but it takes a greater quantum shift to fully transform to a 4th person perspective at Synergist.

Coaching in Awareness and Mentoring in Application

A key dynamic in the coaching conversations was the intention given to both raising self-awareness as well as learning to actively express oneself and engage others from a Synergist 4th person perspective. Qualities such as wisdom and compassion, embracing all people despite their idiosyncrasies and inability to meet all performance goals, thinking through second and third feedback loops in relation to generating new ways of approaching situations, and ultimately thinking synergistically and focusing on the people over and above immediate performance outcomes, trusting that these would ensue, were all embedded in the coaching conversations.

---

[2] The Figure-8 Operating System concept is further enhanced by a correlation with human faculties and the energy fields of a person's life experience in the author's book, Executive Coaching in Strategic Holistic Leadership (2020) McGraw Hill.

The coach's mentoring in empowering Organisational Development methods that the coachees were aware had worked very effectively for the coach earlier in her career, significantly reduced the career risk a senior leader tends to associate with experimentation. The success and increased confidence they enjoyed following the implementation of proven practical engagement processes, encouraged further experimentation.

The executive coaching morphed into mentoring in organisational development that was vertically informed. The instructive mentoring nature of the executive coaching is not typical of developmental coaching which is characterised by the art and science of asking clean open questions. Indeed, the executive coaching in drivers 3 and 4 went well beyond the person to focus almost exclusively on re-engineering the organisational context. This suggests that expediting later stage development to Synergist demands a coaching and mentoring approach with a view to uplifting the leader's collective context. One coachee said in hindsight:

> *Antoinette guided me in a strategic sense and gave good advice yet didn't tell me how to do my job. I involved everyone, listened to everybody and people felt that they were important, and their contribution was valued. I tried to do the things a Synergist would do and be seen to do.*

Transformative Coaching with a Later Stage Executive Coach

While performance coaching is highly process-centric focused on achieving specific goals e.g. the GROW process (Whitmore, 2009), and developmental coaching is highly person-centric (Rogers, 1961) and focused on the art of asking open questions, transformative coaching is a term used to reflect the latest thinking in transformational coaching and 3rd generation coaching (Stelter, 2014). It is a more collaborative process that invites both the coach and coachee to reflect and offer insights on situations and challenges the coachee is occupied with.

The transformative coaching approach provides a later stage executive coach with much greater discretion to share deeper and more expansive meaning-making frames and insights to interpret events, reconstruct narrative and integrate identity. Given the level of guidance that can be offered graciously in this way to expedite vertical development, it suggests that transformative coaching may also have played a significant role in expediting the shift from Achievist to Synergist. Further exploration of the coaching approach is beyond the scope of this paper.

Generating Trust & Confidence by Holding Psychologically Safe Space

The interplay of the four drivers in holistic leadership development reminded me of 'waking up, showing up, cleaning up and growing up'. Together, imagined as four concentric propellers,, they created safe, secure, supportive and sacred emergent space around the self and inclusive of others. This is precisely what the Google Aristotle research project discovered about its highest performing teams. The key factor that distinguished them from the rest was their sense of psychological safety (Delizonna, 2017).

Setting an Aspirational Leadership Brand Declaration was cognisant of ‘waking up’ to one’s aspirational self. Exercising positive kindness and demonstrating mindfulness was a way of ‘showing up’ consistently as one’s best self. Resolving emotional triggers and personal shadow issues was a way of ‘cleaning up’ one’s past. And holding high standards, clear boundaries and strategic priorities with Caring Courageous Conversations (CCC) exemplified ‘growing up’. By living the four holistic drivers, the coachees generated the psychologically safe, supportive and sacred space to liberate the human potential of others to develop vertically and together generate strong performance outcomes. Thus, the interplay of the four factors had a much greater effect than the sum of the parts.

The space that was effectively held by the emerging 4th person leader in the outer zone of the collective synthesises the manifestation of the Synergist. This is extended to the broader organisation and wider community of stakeholder interests through the strategic drivers bringing people together to set evolutionary direction and work together in empowering and heartfelt ways (Drivers 5 and 6) with an aspirational unique living signature presentation (Driver 7) to encourage listening, learning, discovery, healing and collaboration (Driver 8).

The Emergent Three Principles that Underpin Vertical Development Theory

On revisiting Boyatzis’s (2008) Intentional Change Theory and, in particular, its focus on the Ideal Self, the Dynamic Dialogical Model set out by Cavanagh (2013) and the importance of psychologically safe space as set out above, a new Vertical Development Theory emerged. It sets out the three distinctive audiences: the self, the organisation and the wider community, the drivers of development extended to number 9, the 6 active ingredients that enlivened the operating frameworks, and the shared sacred space of mutual inquiry and meaning-making between coach and coachee, were interconnected by three prevailing principles:

INTENTION Purposeful evolutionary aspirational intent for self, organisation and community;

INTERACTION Proactive open respectful orchestrated engagement as a consistent priority with internal and external stakeholders in the spirit of appreciative inquiry; and

INTEGRATION A process of engagement that invited listening, liberated voices and caring courageous collaborative conversations, enabled healing and integration within self and with others.

The concerted attention given to these audiences to courageously collaborate on aspirational endeavours and purposeful initiatives, was held by a sacred space of mutual inquiry, trust and transcendent meaning making led by the perspective and presence of a later stage executive coach. They combine to expedite and extend vertical transformation, as shown in Figure 5 picturing the emergent Vertical Development Theory.

Implications and Research Recommendations

Implications of the Research Study

The paper concludes with a set of implications for executive coaches and facilitators of advanced leadership development programs with a view to utilising the research findings to expedite the shift of many more strategic leaders to the stage of Synergist.

The active experimentation, demonstration and consolidation of Synergist leadership capacity happens in the workplace. The shift in consciousness takes place in the Outer Zones in the Collective (O'Fallon, 2011) and therefore is a matter of experimentation and implementation in the workplace itself. Designers of advanced strategic leadership programs often held offsite over intensive periods of time, should therefore consider extending their programs to include transformative coaching with later stage executive coaches to support their evolution.

Secondly, transformative executive coaching with a later stage executive coach is able to expedite the quantum shift from Achievist to Synergist in ways that developmental coaching cannot. Without the transformative insights and illuminating leading questions posed from a mature Synergist 4th person perspective or beyond, the coachee is not able to receive the gracious guidance of wisdom gained from a person who has already navigated the equivalent developmental pathway, ideally also in a corporate environment.

There is some argument in the coaching literature as to the comparative advantages of having a corporate business background or a background in psychology in relation to coaching effectiveness. It would seem that to expedite the shift to Synergist, a combination of the two is most useful. A mentor with proven knowhow in organisational evolution to green and teal would also support the shift to Synergist provided the holistic leadership development was also taking place with the guidance of a coach with an understanding of shadow integration.

The effectiveness of executive coaching and leadership programs can be objectively measured in terms of vertical development. Coachee perceptions and 360 assessments are mostly associated with horizontal learning capabilities up to Catalyst. If strategic leaders are to evolve to a level where they can transcend and transform conventional paradigms, it is essential to measure coaching effectiveness in terms of vertical development.

The emergence of Vertical Development Theory offers new insights into how a strategic leader might effectively and even expeditiously navigate their journey to a 4th person perspective. This theory can inform advanced leadership development programs of the power of purposeful, evolutionary and aspirational intention; open, respectful and orchestrated interaction; and caring, courageous and collaborative integration to enable evolution.

Future Research Recommendations

While coaching techniques or interventions have not been found to be highly influential in coaching effectiveness previously (De Haan et al, 2013), this case study suggests that a particular spread (strategic and holistic) and range (awareness and application) of coaching interventions with a later stage coach were critical to expedite later stage shifts to Catalyst and Synergist. More research into the type of coaching interventions and the self of the coach as the primary instrument of development, could prove to be very valuable.

It is time to relinquish executive coaching as a one-size-fits-all approach and begin to explore more closely the types of executive coaching, performance, developmental and transformative, and the coaching techniques and approaches that are most useful in relation to the transformations in vertical development. It would be very useful to research how different types of executive coaching impact the transformations in vertical development and the evolution of organisational culture (Athanasopoulou & Dopson, 2018). They may well be inextricably connected.

Further exploration of Vertical Development Theory and its application to executive coaching could enable advanced leadership development programs to be more effective in ushering in more visionary, inspiring, transformative, aspirational leadership in organizations and indeed, in national and international political systems.

Finding Truth Within: Exploring the Importance of Reflective Practice in Deepening Self-Knowledge

Jason P. Miller[1]

Executive Summary

Background Information (Organizational Context)

Healthcare as an industry is undergoing significant and rapid change with a paradigmatic shift from sick-care to preventive care for well-being (Goozner, 2019). This industry shift is demanding a new skill-set from healthcare leaders that is marked by the need to drive transformative change in the face of unprecedented uncertainty, ambiguity, and complexity. A meta-competency that is critical for success in this context that we are building in our leadership development efforts is emotional intelligence (EQ).

Statement of the Problem

Healthcare leaders are much more tuned to be successful in the old paradigm of healthcare than the new one. As healthcare transforms, leaders also need to transform the way they lead. The new leadership profile for success is characterized by a leader who is able to operate as an interdependent, learning-oriented driver of transformative change. To get there, healthcare leaders need to have the ability to self-reflect to gain deeper self-knowledge for purposes of accelerated development.

Guiding Questions

- How does the application of more consistent reflective practice affect the levels of an individual's self-knowledge?
- What are some of the barriers to engaging in reflective practice?
- What are the potential predictive indicators of the extent someone will engage in reflective practice?
- What are the opportunities to enhance reflective practices leveraging mindfulness and/or spirituality?

---

Method of Inquiry

The method of inquiry used in the research is action inquiry, which is "a kind of behavior that is simultaneously productive and self-assessing" (Torbert, 2004). The framework helps to meet the needs to transform healthcare leaders for purposes of transforming their organization. To conduct the study, I taught a reflective practice exercise based on the action inquiry framework to a group of Director-level healthcare leaders as part of a high-potential development program within a large-scale health system (roughly 29,000 total associates) based in the United States Midwest. Components of mindfulness and spirituality were also integrated into the practice. The exercise was designed to deepen their self-knowledge of their personal "defensive routines", which are psychological coping strategies for dealing with stress situations (Boyatzis & McKee, 2005). At the end of eight weeks of participants engaging in the reflective practice exercise, I assessed their levels of self-knowledge gained from the reflective practice, and determine what the primary barriers were for those that did not deepen their self-knowledge.

Conclusions and Recommendations

The results of the study suggest that individuals who engage more consistently in reflective practice seem to have bigger gains in self-knowledge. Also, engaging in reflective practice seems to contribute to the gain of self-knowledge, regardless of the frequency. An individual's development level seems to play a role in the extent to which he/she engages in reflective practice, and also on the nature of what they reflect on. Barriers to reflective practice also seem to be shaped by development level, with informational being primary for earlier stage and motivation being a primary barrier for later stages. Also, individuals who reflect on emotional and physical stress patterns, and who practice mindfulness, seem more likely to engage in reflective practice more frequently. Spiritual practice was not identified as a primary contributor to gaining self-knowledge and requires further study. Additional research is also recommended on the impact of development level on how an individual engages in reflective practice, for purposes of individualizing the development experience.

Introduction

Background Information

I conducted my study as an action research project within the context of my workplace, a large-scale health provider based in the Midwest region of the United States. The organization is the largest healthcare system within the geographic central region of its state, with 29,000 associates providing care through over 200+ locations. The organization is also one of the most profitable and consistently-ranked high-quality healthcare systems in the country. And, the associate culture has been nationally recognized through Fortune magazine's "Best Places to Work" list for thirteen years in a row.

It is also a time of significant and rapid change in healthcare. The industry and reinforcing systems have been built around one common assumption, which is to take care of the sick. A new model of healthcare is already taking shape – one that is characterized by a preventative and more holistic approach to nurturing well-being (Goozner, 2019). The question has become one of how to keep people out of the hospitals to begin with, while educating patient communities on creating paths for a higher quality of life. This has clear implications for leadership. The new healthcare leader can no longer simply be a reactive fixer of problems of the sick but rather a proactive steward of well-being for the community. It is nothing less than a complete paradigm "flip" for healthcare leaders and clinicians, who require a whole new set of skills to be drive systemic change.

In the rapidly-changing context of healthcare, leaders have to make quick decisions in a time of increasing uncertainty, ambiguity, and complexity. And, they can no longer ignore the mission of the organization: to improve the health and well-being of those we serve. "Those we serve" includes not only patient communities, but also our own team members and associates, who are experiencing unprecedented levels of burnout. In addition, the leaders themselves have to role model the way by being in tune with and making decisions in support of their own health and well-being. A meta-competency for success in this new context – and one that we are heavily investing in developing - is emotional intelligence (EQ).

Project Purpose

A sampling of the literature from the fields of emotional intelligence (Gardner, 2011; Goleman, 1998; Goleman, Boyatzis, & McKee, 2013) and developmental psychology (Kegan, 1982; Cook-Greuter, 2013; Torbert, 2004) all suggest that reflection and introspection is a critical capability contributing to personal growth. The common theme suggests that the more disciplined an individual is at engaging in consistent self-reflection, the more likely they will develop higher levels of emotional intelligence (Goleman, 1998, p. 4) and progress on developmental levels (Cook-Greuter, 2013, p. 43, 60).

Emotional intelligence is frequently called a meta-competency because to be considered proficient in EQ, there are a number of capabilities and skills that one needs to master. Given the complexity of EQ as a whole, it was much too broad for the scope of my study. I was able to better focus my scope by drawing in particular off of the literature from the organizational psychology spirituality in the workplace domains. Most notably, Eurich (2017, p. 98) and Wigglesworth (2014, p. 48) suggest that self-knowledge provides us with a deeper understanding of self; one that is achievable through reflective learning and self-inquiry. I therefore narrowed the frame of my research question to the following: how does the application of more consistent reflective practice affect the levels of an individual's self-knowledge?

The insights from this question are important because it will help to more fully inform the significance level of reflective skills and practices as a part of leadership effectiveness. This study has the potential to help me in determining the right levels of focus we should pay in our leadership development curriculum. In addition, participants in the study have the potential to benefit by gaining new insights on themselves, which should help them to be more impactful, develop more self-efficacy, and/or change inner and behavioral habits that are no longer serving them or others.

Problem Statement

Perhaps the best way to sum up the problem is to borrow a quote from Kegan and Lahey:

> We're already the most over-informed, under-reflective people in the history of civilization" and that "true development is about transforming the operating system itself, not just increasing your fund of knowledge or your behavioral repertoire. (Kegan & Lahey, 2009, p.6)

As the rules of healthcare change, provider organizations have to transform how they deliver care to patients, and need to evolve to be much more nimble, adaptive, and predictive than the old healthcare paradigm. This requires a transformation in how our leaders lead. The vision, strategy, operating procedures, and how they engage their people needs to be radically different. To get there, we need to accelerate our leaders' ability to shift from what Kegan & Lahey (2016) call the "socialized mind" (a faithful follower who seeks direction) to the "self-authoring mind" (an independent agenda-driving problem-solver) and further on to the "self-transforming mind" (an interdependent, learning-oriented problem-finder) (p. 62). Boyatzis's Theory of Self-Directed Learning shows that leaders intentionally change only by engaging in an honest and open self-assessment of who their "real self" is against the "ideal self" (Goleman, Boyatzis, & McKee, 2013, p. 109-113). By this account, leaders' ability to self-reflect to gain deeper self-knowledge serves as the critical ingredient to transforming healthcare organizations.

Guiding Questions

In leading my research, I am leveraging the following questions to guide my focus:

- How does the application of more consistent reflective practice affect the levels of an individual's self-knowledge?
- What are some of the barriers to engaging in reflective practice?
- What are the potential predictive indicators of the extent someone will engage in reflective practice?

- What are the opportunities to enhance reflective practices leveraging mindfulness and/or spirituality?

Literature Review

The guiding questions shaped the literature review across five primary domains coming largely from fields of study in the psychology, management, leadership, and spiritual disciplines. Below is a summary of insights relative to the research questions.

Ego Development Theory

Since the development of leaders is the primary task this research project serves, the literature review will start with a brief review of ego development theory. It is important to understand how reflection and self-knowledge contributes toward developmental progression. The following is a sampling of key contributors to how adults develop and progress over time.

Kegan (1982) points out that movement from simpler levels of meaning making to more complex levels requires individuals to dialogue with themselves. They must be self-reflective and able to isolate their motivations, as well as integrate perceptions of their own needs with the needs of others. Individuals with meaning making systems in which they can differentiate between themselves and others indicates the presence of a reorganized interior life in which the individual can internally consider the other when thinking, feeling, and acting. It is both an internal transformation and reconstitution of the self that leads to more complex ways of meaning making, by which individuals are able to identify their impulses and consider the interactions that could result from their actions.

Cook-Greuter (2013), in building off of the work of developmental psychologists Loevinger (1976), Graves (1974), Kegan (1982), and Commons & Richards (1984) in particular, show how the ability to self-reflect on broader dimensions of self, society, the world, and the universe is a critical capability in developing cognitive, emotional, and behavioral aptitude. “As healthy development unfolds, autonomy, freedom, tolerance for difference and ambiguity, as well as flexibility, self-awareness, and skill in interacting with the environment increase while defenses decrease” (Cook-Greuter, 2013, p. 3). While all stages of development require a greater ability to self-reflect to gain self-knowledge, two stages in particular seem to evolve largely from a leap in this capability. For the stage called the “Achiever”, which is where a large majority of leaders reside today (Torbert, 2004, p. 79), “personality tests, asking others for feedback, taking educational and professional courses and retreats as well as a new level of introspection lead to increasing self-knowledge” (Cook-Greuter, 2013, p. 43). Going to the next stage beyond Achiever, known as the “Individualist” stage, there is also a momentous shift that occurs in moving from the “Conventional” to the “Postconventional” tier of development (Cook-Greuter, 2013, p. 6). “The very heightened capacity to contact the self and to introspect leads to a greater capacity to empathize with others and to tolerate different ideas, behaviors, and reactions” (Cook-Greuter, 2013, p. 60).

Beck and Cowan (1996) build off of the work of Graves (1974) in the use of a human evolutionary model called spiral dynamics (Beck and Cowan, 1996; Graves, 1974). To evolve, Beck and Cowan argue that “sufficient human cognitive capacity is needed to enable man to obtain the necessary insight into, and understanding and comprehension of, the complexity and nature of the life conditions. When man was finally able to see himself and the world around him with clear cognition, he would find a picture that is far from pleasant” (p. 112).

Torbert (2004) proposes that “self-transformation…is a long, lifetime path” that sees us passing through major stages called an “action-logic: an overall strategy that so thoroughly informs our experience that we cannot see it” (p. 66). Through the iterative use of action and reflection (Torbert’s “action inquiry” framework) an individual can develop through action-logics of increasing levels of self-awareness, complexity of thought, and abilities to self-transform (p. 68).

Emotional Intelligence and Leadership

How critical is reflection to building emotional intelligence? In the Theory of Personal Intelligences, Gardner divides personal intelligence into the intrapersonal (involved chiefly in an individual’s examination and knowledge of his own feelings) and interpersonal (looks outward toward the behavior, feelings, and motivations of others) (Gardner, 2011, p. 255). He believes that these two forms of knowledge are intimately intermingled in any culture. Neither form of intelligence can develop without the other (Gardner, 2011, p. 255).

Goleman (1998) talks about the importance of the “inner rudder” as the basis for all emotional intelligence (chapter 4). “People who follow their inner sense of what is worthwhile minimize emotional static for themselves” (p. 58). Goleman goes on to emphasize “intuition and gut feeling bespeak the capacity to sense messages from our internal store of emotional memory – our own reservoir of wisdom and judgment. This ability lies at the heart of self-awareness, and self-awareness is the vital foundation skill for emotional awareness, accurate self-assessment, and self-confidence” (p. 61).

Goleman, Boyatzis, & McKee (2013) say that the “most telling sign of self-awareness is a propensity for self-reflection and thoughtfulness. Self-aware people typically find time to reflect quietly, often off by themselves, which allows them to think things over rather than react impulsively. Many outstanding leaders, in fact, bring to their work like the thoughtful mode of self-reflection that they cultivate in their spiritual lives. For some this means prayer or meditation; for others it’s a more philosophical quest for self-understanding” (p. 40). Further, “to connect with a vision that can move a culture toward resonance, emotionally intelligent leaders start by looking inside – at what they feel, think, and sense about their organizations. Tapping into insight can come more easily if a leader makes a habit of reflecting on a regular basis. Reaching into the wisdom of the unconscious mind is like trying to pump water from a deep well – it helps to keep the pump primed (by regularly spending time in reflection)” (p. 205).

Cashman (2017) makes the case that “With no reflection, there is no vision. With no vision, there is no leadership” (p. 170-171), and throughout his text stresses the importance of “taking time to reflect – taking time to be… as the still point that everything else (resilience, actions, vision) revolves around” (p. 164).

In looking specifically at the field of healthcare, the literature consistently points to the importance of emotional intelligence as a critical competency for leaders, with reflection being one of the key dimensions to cultivate. Freshman & Rubino (2002) define the self-management component of emotional intelligence as the "propensity for reflection, ability to adapt to changes, saying no to impulsive urges", citing how "EI skills of self-awareness, reflection, intuition, and compassion for yourself and others will be of great service toward using energy stirred up by emotional events in productive ways" (p. 8). In a review of literature on the importance of emotional intelligence in nursing leadership, Feather (2009) mentions a study by Segal (2002) which identifies "tuning inward" (p. 379) as a suggested competency that makes a person a good leader. And, in a review of leadership education occurring in medical education of physicians, Mintz & Stoller (2014) found that "models of professionalism have been constructed around EI as a leadership skill" (p. 26). In citing one example, the authors note the important inclusion of "structured reflection, which aligns well with the EI competency of self-awareness" (p. 26).

Reflection, Introspection, and Metacognition

Reflection has a long history in the field of organization development. OD researchers recognized the importance of reflection for better decision-making. In a classic organization development publication, Argyris & Schon (1974) introduced the notion of differences between "espoused theories" and actual "theories-in-use" (p. 6-7). They argued that to help someone get to see actual theories-in-use requires self-examination of assumptions through "double-loop learning." Through double-loop learning, an individual can engage in two kinds of behavioral learning at the same time through reflection. The first learning centers on the adoption of new action strategies to achieve governing variables, and the second learning centers on changing the governing variables themselves (p. 18). They say that "the theory-builder becomes a prisoner of his programs if he allows them to continue unexamined indefinitely. Double-loop learning changes the governing variables (the "settings") of ones' programs and causes ripples of change to fan out over one's whole system of theories-in-use" (p. 19).

Schon (1983) extended the notion of reflection for effective applied practice by pointing out that "the process of reflection-in-action is central to how well people deal with situations of uncertainty, instability, uniqueness, and value conflict" (p. 50). He proposes that "through reflection, a practitioner can surface and criticize the tacit understandings that have grown up around the repetitive experiences of a specialized practice, and can make sense of the situations of uncertainty or uniqueness which he may allow himself to experience" (p. 61). When applied to the practice of leadership, this would take the form of reflecting in-the-moment on strategies and schema that directs actions. In an article that applies Schon's work to a healthcare setting, Fransson-Sellgren, Wahlstrom, & Sandahl (2009) state that "part of leadership education involves professional and personal development. The role of reflection is central for professional development." (p. 162)

Torbert (2004) took reflection-in-action a step further with "action inquiry", which he defines as "a kind of behavior that is simultaneously productive and self-assessing" (p. 13). Torbert proposes to be truly effective, you need to choose "timely action" (p. 13) which relies on our capacity to engage in single (behaviors/operations), double (strategy/structure/goals), and triple (attention/intention/vision)-loop feedback (p 18-19). Triple-loop feedback is described as a "super-vision", which refers to a higher quality of awareness – a more "sinuous, just-in-time awareness that generates the exercise of vulnerable, mutuality-enhancing, transforming power under real-time pressures" (p 21). To develop "super-vision", Torbert offers the primary vehicle of self-reflection by "beginning to recognize how limited our ordinary attention and awareness is… and beginning to exercise our awareness in new ways in the midst of challenging situations. A good way to begin recognizing the limits of our ordinary attention is to take a moment right now to reflect" (p. 21).

In review of common competencies for healthcare managers, Stefl (2008) leverages a "skill acquisition model developed by Stuart Dreyfus and Hubert Dreyfus (1986)" (p. 365). As a part of this model that has been extensively leveraged in healthcare leadership development, Dreyfus and Dreyfus point out that "progressing from one skill level to another, especially from novice to competent, typically requires experience coupled with guided reflection" (p. 366).

Csikszentmihalyi (1990) argues that we are ultimately the agents of our own experience, regardless of what is happening around us. "We create ourselves by how we invest this energy. And it is an energy under our control, to do with as we please; hence, attention is our most important tool in the task of improving the quality of experience" (p. 33). He goes on to describe what he calls the "autotelic personality", which are "people who need only a few external cues to represent events in consciousness…[and] have a more flexible attention that allows them to restructure experience more easily, and therefore to achieve optimal experiences more frequently" (p. 87).

Interestingly, it seems that action may be preferred over reflection for most. In examining the impacts of thinking over action for learning, Di Stefano, et. al, (2015) found that individuals who are given time to reflect on a task improve their performance at a greater rate than those who are given the same amount of time to practice with the same task. However, they also found that if those same individuals are given the choice to either reflect or practice the task, they prefer to allocate their time to gaining more experience with the task– to the detriment of their learning (p. 25).

The case for reflection for self-knowledge up to this point seems fairly sound. However, more recent research on reflection, introspection, and pursuit of self-knowledge suggests it is not so clear-cut. As mentioned earlier in this paper, Eurich (2017) found from meta-analyses and her own research that "thinking about ourselves [isn't] correlated with knowing ourselves. We can spend endless amounts of time in self-reflection but emerge with no more self-insight then when we started" (p. 98). Wilson and Dunn (2004) point out some of the inherent challenges of relying too much on introspection for building self-knowledge: "because of personal motives and the architecture of the mind, it may be difficult for people to know themselves. People often attempt to block out unwanted thoughts and feelings through conscious suppression and perhaps through unconscious repression, though whether such attempts are successful is controversial. Introspection cannot provide a direct pipeline to these mental processes; though some types of introspection may help people construct beneficial personal narratives" (p. 493).

Stein and Grant (2014) seem to support this when they found that dysfunctional attitudes (negatively biased assumptions and beliefs regarding oneself, the world, and the future) suppress the relationship between self-reflection and self-insight (p. 505). And, in a study from an earlier year, Grant (2001) focused on the relationship between an individual's psychological mindedness (their predisposition to engage in reflection on why one and/or others behave, think, and feel in the way that they do) and their ability to gain self-insight (p. 12). He suggested that the predisposition is comprised of both abilities and motivations, and that an individual's psychological mindedness could be seen by the extent in which they engage in reflective acts and their level of insights that they gained (p. 16).

If reflection and introspection in themselves are not such clear-cut paths to self-knowledge, what are? Eurich (2017) contends that "the problem with introspection, it turns out, isn't that it's categorically ineffective, but that many people are doing it completely wrong" (p. 100). She goes on to offer some tools that will help to ensure that introspection is more productive including various forms of mindfulness (p. 137-151) and receiving, reflecting, and responding to feedback from others (p. 196-197). Grant, Franklin, and Langford (2002) offer that "conscious and purposeful self-reflection lead to greater self-insight" (p. 831). Stein and Grant (2014) found that facilitating a "positive core self-evaluation" had a mediating effect on dysfunctional attitudes (p. 505). And, Wilson and Dunn (2004) suggest that observing our own behavior and looking at ourselves through the eyes of others can contribute to self-knowledge (p. 493).

Mindfulness

Interest in mindfulness has significantly grown in the past few decades. Increasingly it is the point of study as a tool for building self-knowledge (Eurich, 2017; Boyatzis & McKee, 2005; Carlson, 2013). Boyatzis and McKee (2005) connect mindfulness cleanly to becoming an emotionally intelligent leader – what they call the "resonant leader". They define mindfulness as "the capacity to be fully aware of all that one experiences inside the self – body, mind, heart, spirit – and to pay full attention to what is happening around us – people, the natural world, our surroundings, and events" (p. 112). They argue that mindfulness and self-knowledge are inseparable: "knowing yourself enables you to make choices about how you respond to people and situations. Deep knowledge about yourself enables you to be consistent, to present yourself authentically, as you are" (p. 120). Incorporating mindfulness, they argue, happens only through a process of "reflection, practice, and supportive relationships" (p. 137). They emphasize the importance of prioritizing reflective practice "whether through meditation, spiritual practice, walking in natural, beautiful surroundings, or writing one's personal thoughts and feelings in a journal" (p. 138).

There is an abundance of literature in the psychology field showing how mindfulness can help to lower inner emotional defenses and improve cognitive functioning, which can clear a path for individuals to learn more about self. In reviewing just a few of these studies, Ghasemipour and Ghorbani (2013) offer mindfulness as a pre-reflective activity, rather than reflective itself, calling it an "aspect of experiential self-awareness" that supports mental health by "disengaging individuals from automatic thoughts, habits and unhealthy behavior patterns" (p. 1031). Zeidan, Diamond, and Goolkasian (2010) showed how mindfulness meditation improved cognitive functions such as visuospatial processing, working memory, and executive functioning (p. 597). In leveraging a mindfulness-based approach to cognitive therapy, Britton, et al., (2012) were able to reduce emotional reactivity to social stress in their subjects (p. 365).

In a study that is highly relevant to the primary research question at hand, Carlson (2013) directly explored how mindfulness serves as a path to overcoming barriers to self-knowledge (defined as "the accurate perception of one's thinking, feeling, and behaving", p. 174). He argues that in order to achieve self-knowledge, "people must observe themselves engaging in a behavior that is relevant to a specific trait and then accurately infer the meaning of that behavior with respect to the trait" (p. 174). Further, he reinforces the notion that introspection and reflection are a faulty path toward self-knowledge, saying "people tend to place a great degree of trust in their introspections, but generating explanations for one's tendencies seems to make self-perceptions less accurate" (p. 175). This is due, he claims, to people inherently having two primary inner barriers to self-knowledge: informational (the individual literally does not have access to all needed information) and motivational (the individual does not have the desire to learn) (p. 174-175). In a meta-analysis, he finds compelling evidence that mindfulness appears to directly address these barriers (p. 177-179). He reasons that "introspections are often wrong, and introspecting about the causes of negative emotions seems to have negative mental health outcomes. The key difference is that [introspection] involves analyzing, explaining, or interpreting what is observed whereas mindfulness involves observation of one's experience without telling a story" (p. 176). Therefore, "paying more attention to one's current experience may help a person to overcome many informational barriers, and nonevaluative observation may help one to overcome motivational barriers to self-knowledge" (p. 176).

Mohapel (2018) leverages neurobiology research to make a strong case for using mindfulness as vehicle for building leadership effectiveness in healthcare. In his review of research, he summarizes that "researchers have studied the impact of interruptions and distractions in healthcare settings and have concluded that they interfere with various kinds of higher order thinking tasks, many associated with effective leadership" (p. 87). From a neurobiology perspective, "excessive multitasking appears to…diminish our focus and concentration. In contrast, mindfulness practice is shown to have the opposite effect by…enhancing leadership focus that can lead to greater flexibility, foresight, regulation, and creativity" (p. 87). Therefore, he argues that mindfulness is critical to leadership effectiveness in healthcare in particular because "healthcare environments are increasingly hectic, demanding, and time constrained, with managers and professionals experiencing constant interruptions" (p. 87).

Finally, Wasylkiw, Holton, Azar, & Cook (2015) conducted a pilot study of 11 mid-level healthcare managers on the impact of mindfulness on leadership effectiveness in a health care setting. Participants showed significant positive changes in their leadership effectiveness that was corroborated by informants. However, they also found that the constant activity and change that the mid-level managers face on a daily basis presents significant challenges to sustain a mindfulness practice (p. 893).

Given the evidence from a brief review of literature, it seems that the incorporation of mindfulness practice is an important consideration as a means to deepening self-knowledge. Special considerations should be made in how to make it impactful in the healthcare setting.

Spirituality

Like mindfulness, spirituality has been increasingly making its way into the workplace in recent decades. There is a growing body of literature on how organizations are benefitting by cultivating soul and spirit in their leaders and employees.

The review of workplace spirituality starts with Wigglesworth (2012), a text that is referenced in the introduction of this paper on building spiritual intelligence. Firstly, Wigglesworth defines spirituality as the "innate human need to be connected to something larger than ourselves, something we consider to be divine or of exceptional nobility" (p. 8). As mentioned earlier, Wigglesworth identifies self-knowledge as "the foundation for becoming the wise, compassionate, and peaceful person you have the capacity to become" (p. 48). She suggests that an individual can increase self-knowledge by tending to one's awareness of five specific skills: (1) worldview; (2) life purpose; (3) values hierarchy; (4) complexity of inner thought; and (5) the difference between ego self and higher self (p. 48). She says that "a spiritually intelligent person learns to shift in the midst of the challenging moment to prevent the ego from driving her reactions" (p. 132). To cultivate this, Wigglesworth offers an extensive reflective practice that integrates techniques in mindfulness, prayer, self-observation, mental reframing, and gratitude to "choose a spiritually intelligent response" (p. 132-133). While she does not say it overtly, Wigglesworth is suggesting that the path to self-knowledge is through inner work marked by a deep reflective practice that also incorporates a connection to a "Higher Self" (p. 47).

In reviewing a sample of other spirituality literature, while each saying it differently, they all seem to suggest the same as Wigglesworth. Briskin (1998) talks about how "the soul seeks logos, which is associated with qualities such as meaning, understanding, voice, language, and expression" (p. 139). To get there, "Individuals require both reflective time and dialogue with others to achieve logos. The notion of logos suggests that without reflective time our worldview becomes fragmented and chaotic" (p. 139). Dreaver (2000) discusses how gaining inner clarity and paying attention to be the foundation of what he calls obtaining the "core insight – knowing yourself at the deepest level of being" (p. 3). Ashmos and Duchon (2000) offer that "the inner life, for many, is about coming to understand one's own divine power and how to use that divine power to live a more satisfying and more full outer life" (p. 135-136). They suggest that practices such as meditation, self-reflection, and prayer are the ways to cultivate this divine power (p. 137). In applying spirituality to transformational leadership, Scharmer (2018) discusses the importance of "presencing", which is a deeper state of "presence and sensing". He says that "this requires a reflective, meditative capability to effectively access" (p. 10-11). Finally, in separate but related articles, Delbecq (2000) and Levy (2000) draw from an experience in a pilot course on spirituality for business leaders to provide a compelling case for teaching executives deeper reflective practices, such as contemplative prayer. Delbecq, who was the instructor, mentions how "introduction of contemplative practice learning module into the course for MBAs and CEOs led to realizations that entering into a contemplative space led to insights that issues of ego and intellect tied to power and wealth could be addressed" (p. 122). Levy, a participant and a CEO of a notable corporation, shares his personal learning: "The bottom line is that our effectiveness as business leaders is shaped by how well we are able to find inner quiet, how good we are at listening to the inner voice, and how accomplished we become at understanding its message" (p. 131).

In a meta-study on the impact of spirituality in leadership effectiveness within healthcare, Strack, Fottler, Wheatley, & Sodomka (2002) found that "conceptual and empirical research show a strong link between actualized spirituality and effective leadership; effective leaders use their spiritual wisdom, intelligence, and power to benefit others and achieve outstanding results for their organizations" (p. 16). Reimer-Kirkham, Pesut, Sawatzky, Cochrane, & Redmond, (2012) found that spirituality in nursing leadership is a "relatively understudied field" and suggest that more research in this area needs to be done because of the "unprecedented plurality that global migration has brought to modern societies, and spirituality and religion into the purview of nurse leaders" (p. 1029).

The spirituality literature review suggests consideration of cultivating a deeper reflective practice to access something bigger/higher that the self is connected to. There is also a gap in the literature within healthcare, calling for more work to be done in this space.

Insights and Considerations from the Literature Review

Overall, the literature suggests that reflection and introspection does help to facilitate self-knowledge in service of developmental growth. However, measures need to be taken to counter some of the limitations of reflection and introspection. In particular, it seems people need to be taught the skills to reflect properly for purposes of working through ego inner defenses that all people possess. The incorporation of mindfulness, feedback, and spirituality show distinct promise in helping this cause.

Intervention Method and Design

Theoretical Framework

In selecting a theoretical framework as the basis of my intervention design, I wanted to choose a framework that would help to test the basic research question: how does the application of more consistent reflective practice affect the levels of an individual's self-knowledge? I also wanted to choose a framework that would facilitate a thoughtful connection between individual improvement in self-knowledge and the broader system change needs. Torbert's action inquiry framework met these criteria.

Torbert (2004) calls action inquiry "a kind of behavior that is simultaneously productive and self-assessing" (p. 13). As referenced earlier, perhaps the most critical shift that we can help our leaders and organization to make is to become more "self-authoring" and/or "self-transforming" (Kegan & Lahey, 2016). Therefore, this definition meets our needs to transform our leaders to enable transformation of the organization. Torbert reinforces this potential of action inquiry, saying that "such action helps individuals, teams, organizations, and still larger institutions become more capable of self-transformation" (p. 1). Going further, and more directly connecting this to the primary research question, action inquiry enables self-transformation by "carefully attend(ing) from the inside-out to the experiences we have, hoping to learn from them and modify our actions and even our way of thinking as a result" (p.4). With the "promise of transforming power… emanat(ing) from a willingness to be vulnerable to transformation of oneself" (p. 8) as the backdrop, action inquiry provides an ideal framework to leverage for my intervention.

Action inquiry incorporates a whole-systems approach by leveraging a complex interrelationship between three foundational components: perspectives (p. 19); levels of awareness and feedback (p. 18-19); and territories of experience (p. 21-22). For the first foundational component of perspectives, action inquiry takes into account three different perspectives for three different aims: (1) a first-person, subjective perspective, which has the aim to generate *integrity* in ourselves; (2) a second-person, interpersonal perspective, which has the aim to generate *mutuality*; and (3) a third-person, organization, society, and environment perspective, which has the aim to generate *sustainability* (p. 7). For the second component of levels of awareness, an individual can have three different levels of awareness in relation to observed outcomes in the external world: (1) single-loop awareness & feedback, which deals with making choices in behavior; (2) double-loop awareness & feedback, which deals with making choices in setting strategy, structure, and/or goals; and (3) triple-loop awareness & feedback, which deals with what the individual's attention, intention, and/or vision is set on (p. 18-19). For the third and final component of territories of experience, an individual can experience the external world in four ways: (1) first territory, which is neutral observation, inquiring, and assessing of outside events; (2) second territory, which is the individual's own sensed performance of behaviors, skills, and illustrated patterns of activity; (3) third territory, which is the individual's action-logics, or their chosen strategies, schemas, thinking/feeling patterns, and reflection on experience; and (4) fourth territory, which is the individual's intentional attention, presencing awareness, framing, and vision (p. 22). A summary of how the action inquiry components manifest together can be found below in table 1.

Table 1. How the Levels of Awareness and Four Territories of Experience Manifest Themselves in First-, Second-, and Third-Person Perspectives (Torbert, 2004, p. 39).

Territory of Experience	First-Person Attention	Second-Person Speaking	Third-Person Organizing
Fourth Territory	Intending	Framing	Visioning
Third Territory	Thinking/Feeling	Advocating	Strategizing
Second Territory	Sensing/Behaving	Illustrating	Performing
First Territory	Effecting/Perceiving	Inquiring and Listening	Assessing

Research Design

The intervention design began by clarifying intended outcomes. With the scope of research focused on leveraging reflective practice for increasing self-knowledge, it was important be more specific in what it looks and feels like to have gained self-knowledge. While the literature review shows that self-knowledge can include many components, this intervention had a focus on helping individuals to raise their knowledge of mental, emotional, physical, and behavioral patterns in service of understanding what it looks and feels like when the ego self is activated

(Eurich, 2017, p. 32-42; Wigglesworth, 2015, p. 57-65). This is important because the "ego's primary goal is to keep us safe" (Wigglesworth, 2014, p. 60-61) and while that is certainly an important function, "excessive fear activation robs us of joy as well as leadership capacities" (Wigglesworth, 2014, p. 61). Also, given the insights gained from the literature review on mindfulness and spirituality, these elements were incorporated into the intervention as well.

To conduct the study, a reflective practice exercise based on the action inquiry framework (Torbert, 2004) was introduced to a group of eighteen Director-level leaders within the Midwest-based healthcare system who are participating in a high-potential leadership development program. Informed consent of the participants was obtained as part of their onboarding agreement into the program. In addition, the appropriate permission from the internal research organization was secured for the study.

The reflective practice exercise integrated components from Torbert (2004), Wigglesworth (2014), Bolman and Deal (2011), and Boyatzis and McKee (2005). Torbert offers three useful sets of exercises that the design was based upon: (1) practice noticing (p. 56-57); (2) practice naming (p. 57-59); and (3) practice action inquiry (p. 59). To add mindfulness and spiritual components to the practice, the activity incorporated a technique offered by Wigglesworth (2014) to "stop and breathe" in the moment prior to engaging in reflective activities (p. 133-136). A technique offered by Bolman and Deal (2011) to "summon spirit" through "art, ritual, stories, music, and icons" (p. 171) was also included. Finally, Boyatzis and McKee (2005) provided the content foundation for learning about "defensive routines", which they define as "ineffective habits of mind and behavior" serve as "coping mechanisms…to protect or distract us from the discomfort of our current emotional state" (p. 44). See "Appendix A" to see more details on the in-session exercise built to teach this content through a reflective and interactive way.

The exercise asked them to pause shortly after an incident or event in which they experience a stress response or defensive routine to reflect on what is happening within their inner territory (practice noticing). The exercise then asked them to do a brief centering technique first (practice mindfulness), followed by describing as accurately as possible what they are/were thinking, feeling, and physically experiencing in that moment (practice naming). Participants were also asked to share stories and name an image, song, or metaphor that captures the essence of their experience (practice spirituality). To help them, participants received a form to prompt their reflections more consistently. See "Appendix B" for a view the reflective activity.

Table 2. Intervention Timeline.

Phase	Timing	Key Activities
Intervention Design	3/11 – 3/18	Scoped and proposed Designed approach Produced deliverables
Intervention Implementation	3/19 – 5/26	Taught supporting content and instructed participants in the activity at LEAD on 3/19 Observed and monitored progress Assessed outcomes at LEAD 5/21

Intervention Analysis & Findings	5/27-6/9	Analyzed and synthesized data Documented insights and observations Reviewed outcomes relative to research questions
Implications for Practice & Recommendations	6/10-6/16	Formulated recommendations Proposed future research
Produce Final Paper	6/17-7/14	Created final report

Participants were asked to conduct the reflective practice exercise three times per week over a period of eight weeks, documenting what they noticed in a journal. At the end of that time, participants were asked to complete an assessment to gauge how well they could accurately describe their internal thought, feeling, body sensations, spirit, and behavioral patterns, which would offer an evaluation of how much self-knowledge they gained from the reflective activities. Additional inquiries were made as to what barriers might have prevented them from completing the activity as asked, and components of self-knowledge that they found most valuable to explore. Finally, participants were asked to reflect on how their specific attention to and perspective on the entire eight-week exercise affected their experience with it (to practice action inquiry on the process itself). Assessments were collected during the LEAD session in May and served as the primary data to analyze findings.

Results

I will walk through the analysis of my findings by following the basic structure of addressing each of my research questions.

Research Question 1: How does the application of more consistent reflective practice affect the levels of an individual's self-knowledge?

I broke this question down into a two-part analysis. For the first part, I focused simply on evaluating the overall impact that the reflective exercise had on the self-knowledge of participants. I leveraged a question that asked participants to choose from a 5-point Likert scale rating the impact that the reflective exercise had on them, regardless of how many times they completed it. A full 100% of the participants reported gains in self-knowledge from the exercise, with some varying degrees of the extent of impact. Below is a breakdown of these results.

Table 3. Participant responses to question "To what degree would you say that the reflective activity increased your self-knowledge?"

Answer Choices	Response %	Response #
A great deal	29%	5
A lot	29%	5
A moderate amount	41%	7

A little	0%	0
None at all	0%	0
TOTAL	100%	17

To obtain additional insights on the responses above, I evaluated comments that were provided by the participants around two questions: (1) What is your overall perspective on the reflective activity that you completed?; and (2) What difference will this reflective experience make in your life going forward? The most common themes that emerged across participants were learning about emotional responses to stress; increased self-awareness; and overall learning about self.

For the second part, I analyzed the relationship between the frequency of practice and relative gains in self-knowledge. When I introduced the reflective exercise to participants, I asked them to complete it an average of three times per week for a period of eight weeks. I purposely suggested that participants complete the activity on a high-frequency basis to explore potential variability across an expected range of engagement. I asked participants to estimate the number of times that he/she was able to complete the practice over the eight weeks by making one selection from a list of five range options. The ranges were created in a way in which I could assign their frequency performance using percentile rankings. Four of the seventeen participants (24%) met or exceeded the target number of reflection points (high frequency). Another six (35%) completed it at least half of the time (moderate frequency). Seven participants (41%) completed less than half of the time (low frequency). The below table summarizes the results.

Table 4. Participant responses and percentile rankings to question “Approximately how many times were you able to complete the practice over the past eight weeks?”

Answer Choices	Response %	Response #	Percentile
Over 24	12%	2	125th
19-24	12%	2	100th
13-18	35%	6	75th
7-12	29%	5	50th
0-6	12%	2	25th
TOTAL	100%	17	

I cross-referenced the percentile rankings to the self-reported gains outlined in part one above to determine if there was any correlation between frequency of practice and gains of self-knowledge. The analysis showed that those participants who completed the exercise with the highest degree of frequency reported the most gains in self-knowledge. This was true for the group of participants reporting the highest gains (indicated by “A great deal”), but there was not a significant difference between those participants reporting gains of "A lot" and "A moderate amount." The below table summarizes these results.

The final part of my analysis for the first research question was to review comments of participants in response to the question "If you were to do this activity over again, what would you do differently (if anything)?" The common themes across participants were that they started to "gain more when they gave more" and that they would complete the exercise more frequently if they were to do it over again.

An overall interpretation of the findings for the first research question suggests that for this group of seventeen leaders, engaging in the reflective practice exercise in itself contributed to gains in self-knowledge. And, it appears that those individuals who engaged in the reflective exercise the most frequently over an extended period of time experienced the largest gains. These findings imply that there may be a connection between frequency of reflective practice and self-knowledge.

Table 5. Analysis of frequency of practice and degree of gains in self-knowledge.

Answer Choices	**Response #**	**Average Frequency Percentile**
A great deal	5	75th
A lot	5	65th
A moderate amount	7	64th
TOTAL	17	

Research Question 2: What are the potential predictive indicators of the extent someone will engage in reflective practice?

To address this question, I defined three primary categories to analyze in my study. The first category is components of self-knowledge, which in my research design I mention as being mental, emotional, physical, and behavioral patterns. The second category is the special practice focus areas of mindfulness and spirituality. The third category is developmental level. I will walk through my analysis of results that were collected relative to all three categories of potential predictors.

For the first (self-knowledge components) and second (mindfulness and spirituality) categories, the reflective practice exercise was intentionally constructed to engage participants in all components of self-knowledge, as well as a mindfulness and spirituality practice. I leveraged results from a question on the assessment in which I asked participants to rank order the degree of influence that each part of the practice had on their gains in self-knowledge. There were eight total practice steps to rank, each of which represented one of the components to self-knowledge. Since I was interested in determining predictors of frequency of practice, I analyzed each practice step / component separately across all participants. I sorted each step / component from highest to lowest rank (1 being highest, 8 being lowest), then split into a top half (representing a ranking of 1-4) and a bottom half (representing a ranking of 5-8). I then cross-referenced practice frequency percentiles (as assigned in the previous step), noting the numerical spread between the average percentiles between top half and bottom half rankings. This approach showed that participants who ranked emotional and physical practices the highest in influence tended to practice the reflective exercise more frequently. The data also showed that the mindfulness practice was ranked highly amongst high-frequency reflective practitioners. On the reverse side, participants who ranked consideration of impact of actions, mental patterns, and observations of their behaviors as more influential tended to practice the reflective exercise less frequently. Also worth noting is that not one participant ranked the spiritual practice in the top half, so there was no basis to analyze this component. See the below table for a summary of the results.

Table 6. Analysis of reflective practice / self-knowledge components with strongest correlation to frequency of practice.

Practice / Component	**Average Frequency Percentile for Top Half**	**Average Frequency Percentile for Bottom Half**	**Frequency Percentile Spread**
Noticing and naming the specific emotion I feel (emotional)	75th	63rd	+12
Noticing and locating the place in my body that I experience tension (physical)	75th	68th	+7
Pausing and taking deep breaths (mindfulness)	73rd	67th	+6
Examining the overall pattern over longer period of time (meta reflection)	71st	70th	+1
Noticing the actions / behaviors that I demonstrate (behavioral)	70th	71st	-1
Noticing what I am thinking / the story I am telling myself (mental)	70th	75th	-5
Considering the impact of my actions / behaviors on others (impact)	61st	81st	-20
Identifying a song, image, metaphor, and/or story that captures the essence of my experience (spirituality)	N/A	N/A	N/A

For the third (developmental level) category, I leveraged a brief developmental assessment designed by STAGES International (O'Fallon & Barta, 2018) to capture an estimated developmental level of each participant. The assessment is based on an ego development theory model created by Terri O'Fallon, which builds upon previous models mentioned in the literature review (Cook-Greuter, 2013; Loevinger, 1976; Graves, 1974; Kegan, 1982; Commons &

Richards, 1984). The assessment required each participant to complete six sentence stems with a free-form response. I then partnered with trained language and grammar assessors from STAGES who evaluated anonymous responses to each sentence for indicators of developmental level. The assessors assigned a probable developmental level from which each response is most likely associated by assigning it a numerical score. The higher the score, the higher level of development. I was instructed by O'Fallon to simply average the six sentence scores to arrive at an overall probable developmental level of the participant. I then cross-referenced developmental level scores with frequency of practice percentiles to explore the relationship between the two. I found those participants who were between Achiever and Individualist levels, as well as one participant who is between Individualist and Strategist level, to engage in the reflective exercise most frequently. Participants between Expert and Achiever levels were less likely to engage in the reflective exercise as frequently, and those solidly at Achiever level were the least likely. Below is a summary of these results.

Table 7. Analysis of developmental level and strongest correlation to frequency of practice.

Developmental Level	**Average STAGES Score**	**Average Frequency Percentile**
Achiever-Individualist	3.64	79th
Individualist-Strategist	4.42	75th
Expert-Achiever	3.25	69th
Achiever	3.47	60th

An overall interpretation of the findings for the second research question suggests that for this group of seventeen leaders, Achiever-Individualists who practice mindfulness while learning about their emotional and physical response patterns to stress are most likely to engage in consistent reflective practice. On the contrary, Achievers and Experts who do not prioritize mindfulness and focus primarily on their behavior and mental patterns are least likely to engage in consistent reflective practice. Additionally, it does not appear that practicing spirituality as designed in this intervention had much of a factor on frequency of reflective practice.

Research Question 3: What are some of the barriers to engaging in reflective practice?

I examined this research question through two perspectives: (1) Carlson's primary barriers to self-knowledge; and (2) developmental level. For the first perspective, I asked participants to explain what the primary reason(s) were for their inability to complete the reflective exercise less than 24 times (the total one would achieve if fully completing the assignment). Participants could choose up to three reasons why they could not meet the full goal, all of which are tied to Carlson's (2013) theory of barriers being either motivational (lack of desire) or informational (cannot access parts of themselves). The overwhelming reason that participants did not complete the reflective activity was not finding the time to prioritize and/or fully complete, which is a motivational barrier. See below a summary of the responses.

Table 8. Analysis of barriers to engaging in reflective practice.

Reason	Barrier Type	# Responses
Could not find the time to prioritize and/or fully complete	Motivational	13
Difficulty in accurately completing activity	Informational	2
Gap in reflection skills	Informational	2
Attempted but was not gaining any value from the exercise	Motivational	1

For the second perspective (developmental level), I cross-referenced the developmental level numeric scores provided by STAGES International with the reasons provided by participants for not completing the exercise. I found that Achievers primarily experienced motivational barriers while Expert-Achievers primarily experienced informational barriers.

An overall interpretation of the findings for the third research question suggests that for this group of seventeen leaders, the primary barrier to engaging in reflective practice tends to be motivation. The data also suggests that developmental level may potentially play a role in the type of barriers that one experiences to reflective practice.

Implications

Implications for Practice

For me, the biggest surprise of the intervention was the extent that participants engaged in the reflective activity. In my checkpoint with the group at the half-way point, I posted that I was not feeling very confident that people were actually engaging in the activity as designed. There was not a lot of enthusiasm for the activity in our discussions, and those that shared how it was going for them were few. At that time I drew one conclusion that people were not engaging in the activity, and possibly even not seeing it as valuable. However, the data analysis has proven these hunches wrong. Rather, everyone did, indeed, engage in the activity and ALL found it useful in building self-knowledge. And, the more frequently participants reflected, the more they reported gains in self-knowledge and learning (the opposite was true as well, with the theme of participants reporting that they would engage more frequently if they were to do it over again.) This experience has changed my perception of the readiness and willingness of our leaders to engage in deeper, more reflective inner work, and the meaningful impacts this has on them. It also suggests a connection between frequency of reflective practice and self-knowledge, which implies a greater focus on reflective capabilities in leadership development.

Additional insights that I gained on predictors and barriers to reflective practice were also highly useful. The initial findings of this study point to several components that are worth exploring further. Development level, in particular, seems to play a factor in the extent and how an individual practices reflection. The findings that those who are either moving into or are already at Individualist stage reflect more frequently is consistent with the literature on ego development theory and poses some exciting opportunities to more accurately assess the unique development needs of individuals. Also, what participants tend to focus and not focus on, and what barriers tend to be present, is potentially telling. The findings that those who prioritize mindfulness, as well as reflect on emotional and physical patterns, are more motivated to practice more frequently suggest that individuals may use different prioritizing schema and/or hold a differing readiness for reflecting. All of this points to the need to conduct more research for purposes of informing a more individualized approach to developing our leaders.

On the topic of spirituality practice, the data that I collected did not point to any particular compelling insights. This does not mean that this is not an important component of predicting reflective practice frequency, but rather could be an element that was too unique to include as part of this study. When comparing the degree of exposure and learning that we have given this component relative to others in our LEAD program, we have given it far less attention in our curriculum. It could be that it was just too much to ask them to reflect on at this point, which further points to the topic of readiness. This suggests that some element of content coverage is necessary to help participants make meaning out of inner territory.

For my practice, our leadership development programs need: (1) to more fully incorporate reflection as an element of learning; (2) to work on a more individualized approach to development; (3) to include content and frameworks for making meaning out of inner territory; and (4) to work on creating a safe environment for discussing inner territory more openly. It has been easier to create this in our hi-potential programs, which uses an intimate cohort-based approach to learning over a period of time. The bigger challenge will be to create this experience for the masses, which tends to engage in learning on a more episodic level.

Recommendations

This study had a very large scope, and in essence served as a starting point for me to gauge where I need to go further with deeper study. Each of the research questions that I posed could be a study in itself, and in fact could be narrowed even further. Going forward I will take a more focused approach to action research, with a few dimensions in particular calling for further study. This study just touched on the impact that development level has on the extent and nature of reflective practice. There is a lot of opportunity to explore this territory to better understand how individuals learn to reflect, what motivates them to do so, and how this differs (or not) at different development levels.

The special interest areas of mindfulness and spirituality both offer promise of additional research, in different strands. For mindfulness, the results of this study were consistent with other studies cited in the literature review that this could play a key role in helping people to gain more self-knowledge. What are the specific conditions in which a mindfulness practice contributes? What conditions may it not contribute? What are different ways in which individuals could practice mindfulness? What are potential barriers to an individual adopting mindfulness practice? There a many other questions to explore in this rich topic.

For spirituality, this study did not even begin to explore the topic in any meaningful depth. As mentioned in the next steps, I would like to give this topic a bit more due in exploring different ways to research this as an element of building self-knowledge. It starts with getting more defined in my research question, and in designing an intervention that more directly defines and assesses spiritual practice. With the promise offered by the literature review, and the continuing growth in the body of research on spirituality in the workplace, there is a significant opportunity to dive deeper into this dimension.

Additionally, there is a lot of opportunity to further explore how other variables might be shaping an individual's experience with reflection. For example, how does being a part of a hi-potential program like LEAD shape the way an individual experiences reflection and reflective exercises? How much influence does this construct have on an individual's engagement level? Is it different for individuals who are not a part of a unique program like LEAD? One can assume there are other factors involved here that were beyond the scope of this study, but could shed further light on variables predicting reflection.

Finally, I would like to continue to refine my action research methods for future studies. The broad scope of this study, coupled with the narrow scope of the audience, created some inevitable constraints that limit my research and conclusions. The small sample of 17 high-potential director-level leaders is indeed narrow, and I cannot assume that it is representative of the broader population of leaders across the organization. Also, I surveyed a wide range of topics at a higher level, and mostly I gathered data from self-reported insights. The result is that I can only generate curious hunches versus deeper, more definitive conclusions. This suggests that I adopt more focused and sophisticated research methods over time.

Appendix A

Identifying Defensive Routines – In-Session Content Exercise

Step 1: Recall High Pressure Situations. Take a moment and think about 3-4 situations or events in your past in which you were experiencing a significant amount of pressure or higher-than-normal stress. Try to select situations that span your whole life – both professional and personal. Write those down here.

Step 2: Identify your Typical Routines. Check all that apply below. When under stress:

I Approach and Internalize

____ I get to work earlier and stay at work later
____ I continue to add new projects or take on more roles despite a realistic shortage of time or results
____ I constantly remind myself of my own or other's high standards for me
____ I expect everyone to perform at my high standards
____ I can never say "no"
____ I feel a sense of personal obligation to fix everything myself
____ I put others' needs ahead of my own to keep the peace

I Avoid and Internalize

____ Move further inside: my office, my projects, my thoughts and concerns
____ Become detached from relationships with colleagues, friends, and family
____ Communicate in short and direct statements about only "essential" information
____ Only my mission and goals seem important
____ I don't feel I need input from others
____ Other people just get in the way

I Approach and Externalize

____ I am the only one who knows the answer and can fix this
____ If anyone disagrees with me I will disregard them or make them sorry for disagreeing
____ My closest friends and advisors always agree with me
____ I never waiver on decisions
____ I believe that I must win others over

I Avoid and Externalize

____ Focus on negative aspects of situation
____ Wear anger and disappointment on my sleeve
____ Criticize or become cynical, with those who want things to change or have hope
____ Blame my mood/circumstances on situation or someone else
____ Gather and drink with like-minded people and talk about what I think is wrong
____ I move on to better things elsewhere

Appendix B

Self Check-In Activity

10-15 minutes

Directions: Each of us has developed unconscious responses to situations that invoke a higher-than-normal stress response. These are known as “defensive routines”, because our ego perceives the situation has some sort of threat, and this leads us to react in a more protective manner. The purpose of this self-reflective activity is to build awareness and knowledge of what your unique defensive routines look and feel like in greater detail, and the situations and/or people that tend to trigger them.

Take a brief pause while experiencing a higher-than-normal stress response, or shortly after you experience it, and check-in with yourself by answering the questions provided below. You are free to document your responses in this form or a journal, whichever works best for you. Try to complete this activity at least three times per week for the next eight weeks.

Step 1: Pause and Breathe. Take three deep breaths, each one deeper than the previous, and let the air out with large exhales. Or, conduct a brief meditation, whichever you need to shift yourself to a more reflective state.

Step 2: Notice it.

What I am thinking about right now is… [openly write whatever comes to your mind]
Where I am experiencing escalated tension and/or tightness in my body is… [muscle tension, depth of breath, blood pressure / heart rate levels, etc.]
The story that I am telling myself at this moment is… [free-write in an unfiltered way]

Step 3: Name it.
I feel… [use the table below and circle the most accurate descriptor(s)]

Anger	Anxiety	Fear	Joy	Love	Peace	Sadness	Shame
Agitated	Anxious	Alarmed	Alive	Attention	Comfortable	Crushed	Ashamed
Anger	Confused	Defensive	Bold	Caring	Confident	Disappointed	Burdened

The impact these actions / behaviors seemed to make on other(s) was… [be descriptive]
The most important thing to me that this event affects is…
A song, image, metaphor, or story that comes to mind that captures the essence of experience is… [write down whatever comes to mind, regardless of how much "sense" it makes]

Hope Examined Through a Developmental Stage Perspective

A Doctoral Dissertation Research Proposal

Lisa Buckley[1]

Hope seems to be a human function or process that can be catalyzed when facing limitations and uncertainty that separate us from reaching personally significant goals. The contexts vary, for example: being ill and trying to live until one's daughter finishes high school; striving to complete college while raising three children and working two jobs; or struggling to find housing when one's Pacific Island village becomes permanently uninhabitable due to rising seas.

Scholars and laypersons are naming hope as an essential element for dealing with the world's complexities that threaten our very existence. In the last 30 years, hope has been researched across many academic disciplines with most scholars identifying that hope can be learned and facilitated. Much of the hope research in the fields of psychology, palliative care, education, and sustainability is targeted toward identifying effective interventions to assist individuals with well-hoping. *Well-hoping* refers to the pragmatic ways which individuals may best utilize the power or function of hoping. Those scholars and practitioners whose work facilitates well-hoping in individuals and collectives are identified as *hope interventionists.* Hope interventionists include educators, coaches, facilitators, therapists, group leaders, and social activists.

Hope scholars are calling for research to identify the most effective interventions to support individuals to develop capacities related to well-hoping. Identifying individual differences in hoping is another research target. Hope is recognized as a meaning making function that is catalyzed when limitations arise. Currently, research on meaning-making and hope is sought. Since the STAGEs theory and model are based on identifying and working with distinctions in individuals' meaning making systems, there is value in examining hope through a developmental stage perspective.

The question for Lisa Buckley's doctoral research is: *How do adults within distinct developmental stages perceive and experience hope?* The research methodology includes development and use of a stage assessment tool based on O'Fallon's (2012, 2013, 2018, 2019) STAGES assessment model, methodology, and assessment instrument. In addition to developing

and applying this STAGES Hope Specialty Protocol, qualitative interviews of study participants will also be conducted.

The research methodology includes distributing the hope specialty protocol to four individuals who have previously scored in each of the following six stages: Achiever 3.5 through Universal 6.0. With four respondents in each of the stages, there will be a sample sufficient for the Cronbach's Alpha internal consistency measure of reliability for the Hope specialty protocol. At a minimum, two from each developmental stage will be interviewed.

Anticipated date for completing the research is late 2020.

STAGES Child Research: Preliminary Report

Terri O’Fallon[1]

Abstract. The Loevinger Lineage (Loevinger, Torbert, Cook Greuter, O’Fallon) has much data related to adult development. This includes adults that score at very early levels of development, including Egocentric (late first person perspective in the STAGES model), “Rule Oriented” (early second person perspective), and “Conformist” (late second person perspective). Many of the adult populations comprising the Loevinger lineage research-base at the earliest levels come from adults that are compromised in some way. However, very little research has been done related to first and second person expressions of children, which are the primary ages that take these perspectives. This article describes our first attempt to examine the expressions of children at these levels who have normal healthy expressions of these earliest human perspectives.

Introduction

While there may be other Integral Elementary Schools, the Brisbane Independent School (BIS), is the only one I am aware of that is organized around the developmental levels of the children. It is a private elementary school supervised by a teaching principal, Jennifer Haynes. Jennifer has developed a child and teacher curriculum that honors the developmental levels of both the children in the school and the adults that are teachers there. For many years she has followed the children closely through their developmental journey. Parents are very involved in the school as well. Given the make-up of this school (pre-first grade levels through ages 12-13 years old) BIS seemed like the most appropriate site for a research project on normal healthy child responses at the earliest levels of the STAGES developmental model: late first person perspective (1.5), and early and late second person perspectives (2.0 and 2.5).

For reference, the matrix in Figure 1 defines each of the 12 person perspectives in the STAGES model, and their parametric definitions. See other papers in this special issue describing the STAGES model and these levels.

Method

Preplanning for the Research

Ethical research with children as subjects requires parental permission. To accommodate this, our research team (Kim Barta and Terri O’Fallon) prepared a detailed description of our research, honoring the rights of students and their parents. Before we arrived at the school, Jennifer contacted each parent and asked them sign the permission form for doing the testing. She arranged a protected, locked file the names of all of the children being tested the permission forms, that only she has access to. The researchers giving the test to the children would not have access to the children’s identifying information (including parent names).

In the meantime Kim (a psychotherapist that has worked extensively with children of all ages) and I modified our general STAGES inventory to create one that was appropriate for young children. The general inventory has 36 sentence starters each of which the test taker completes. A function is applied to aggregate the scores for each completed sentence into a final score which represents the developmental level ("center of gravity" or "core score") of the test-taker. The standard version of the ego-development test is suited for adults so we looked to see what sentence starters should be replaced with child-friendly sentence starters.

We understood that some sentence starters might be too advanced for the youngest children and yet quite relevant to the older children so we tried to strike a balance between the younger and older children’s needs. 11 new sentence starters were embedded in the general inventory, replacing sentence starters that seemed to not be very relevant to children, for a total of 36 sentence starters. Table 1 shows the new sentence starters in blue. To summarize, we decided to add the following sentence stems: My family, Grandparents, These days, School, My parents and I, A good child, When they didn’t let me join in, Bullying could be stopped if, Children and parents are lucky when, Children who step out of line, A parent has the right to, and A child has the right to. The figure below shows the stems in order of appearance, with the new ones in blue.

Table 1. 36 Sentence Starters for the STAGES Child Inventory.

1. My family	10. When people are helpless	19. Bullying could be stopped if	28. A parent has the right to
2. When I am criticized	11What I like to do best is	20. Children and parents are lucky when	29.If my mother
3. Grandparents	12. A good child	21. I just can't stand people who	30. If I were in charge
4. These days, school	13. We could make the world a better place if	22. At times I worry about	31. My father
5.Being with other people	14. The past	23. I am	32. If I can't get what I want
6. The thing I like about myself is	15. Privacy	24. If I had more money	33. When I am nervous
7. My parents and I	16. I feel sorry	25. My main problem is	34. A child has the right to
8. What gets me into trouble is	17. When they didn’t let me join in	26. When I get mad	35. My conscience bothers me if
9. Education	18. Rules	27. Children who step out of line	36. Sometimes I wished that

Data Collection

When Kim and I arrived at the Brisbane school, Jennifer had already arranged for the research process to take place. Since this required an oral test with the children, she set up two private spaces where we could meet with them one by one. Kim and I went to the various classrooms and the teachers were already prepared to send a child with us when we appeared at their door. We engaged with the children on the way to our private spot, creating rapport with them on the way. Once we got settled with the child, we gave them several sentence starters for practice so that they could understand what the task was. These children had no trouble responding to the 36 sentence starters and most appeared to thoroughly enjoy the process. Several children were very shy and wanted to respond to only a few sentences. This was expected and when that happened we simply went onto the next sentence starter until they indicated that they wanted to respond.

Kim and I typed verbatim their responses to the sentence stems. We collected and transcribed this data of 36 oral responses for each of the 53 children, gathered over two days, for a total of 1908 responses.

The School Environment

Kim and I were invited to visit each classroom so that we could see the developmental process of how the children were organized by their developmental level. As well, we spent time with the teachers to see how they related to the children and their teaching practices.

Jennifer went over the curriculum with us to show how she had designed the school as a developmentally friendly environment for the children. This included recognizing when children were in a transformation and ready to move into another classroom. This could happen any time during the school year and provided for a flexible process for the children, honoring where they were in their developmental journey.

Jennifer invited us to her teacher’s meetings so that we could see the curriculum she had created for them as they experienced their own developmental journey. These teachers were very aware of looking at themselves developmentally and understood how their own developmental level affected their teaching.

For the final days, Jennifer had arranged for Kim and I to put on a two day developmental workshop for the parents, teachers and other community members who were interested. This indeed was a vibrant community of well informed and supportive people who were doing their best to help to create a school that would serve their children. These parents were of all economic levels and were quite diverse.

New Score Aggregation Method

Until recently, we assigned the final score to an inventory using the ogive cutoff approach from the Loevinger Lineage. We had translated this approach to the 12 levels of the STAGES model (1.0, 1.5, 2.0,....6.5).

Recently we have begun using a new formula for aggregating the 36 item scores to get a total score (or "core score"). See the article by Tom Murray on our Ogive and Rash research in this issue for details. The new process returns continuous value between 0.5 and 6.5, rather than forcing the score into categories. This "Core Score" is rounded to the nearest 1/10th of a person perspective (e.g. 3.6). Thus it does not "throw away" information as in done in the cutoff categorization method, and its higher granularity helps us to have a more nuanced score interpretation. As described in that paper, one of the advantages of the new method is that it does not confuse "shadow" elements of a completion with the authentically lower levels of complexity as seen in children. This study is the first published research to use this new method. For convenience in reporting, we will sometimes round off the continuous value to the appropriate whole-level category.

Data Analysis

Once we got back to the US, I entered the children's sentence completion text into our scoring platform and began to score them. I soon realized that the sentence completions of these healthy children were very different from adults that had scored at those levels (including a prison population, and mental health facilities). The typical categories that the Loevinger Lineage had created from adult completions simply didn’t fit with this population of children. For example, a 1.5 adult sentence completion might say “When I am in charge…I would rule the world” while a child would more likely say “...I can’t be in charge – I’m just a kid. My parents are in charge.”

While scoring these inventories, the person perspectives and their paradigmatic definitions were available for analyzing the developmental levels of these 1908 child responses. I worked slowly and carefully with each response, going back and forth between them, comparing them to verify that the three STAGES parameters for each person perspective were honored despite very different responses at each level and between each level. I used the following process for scoring each sentence completion.

1. I scored each completion using the parameters (described below).
2. I compared all of the sentence stems that were scored at the same level to see if any of them seemed to fall prior to or extend later than most of those scores.
3. I rescored these stems and moved back and forth between the meaning making that seemed to lie at each developmental level and also meet the parameters.
4. I checked each completion several times until I was satisfied with the scores.

Validating the Child Inventory

Once the inventories were scored I sent them off to our statisticians to get a Cronbach’s alpha to make sure the internal consistency was adequate.

Table 2. Internal consistency for child protocol stems. N=53 protocols.

Data Subset	Cronbach's alpha
All stems	0.88
Old stems	0.85
New stems	0.63

Conclusion: The overall internal consistency of the child protocols as measured by the Cronbach’s alpha statistic was "good" (α = 0.88), according to the table below.

A commonly accepted rule of thumb for describing internal consistency is as follows:*

Table 3. General Cronbach alphas.

Cronbach's alpha	Internal consistency
$\alpha \geq 0.9$	Excellent
$0.9 > \alpha \geq 0.8$	Good
$0.8 > \alpha \geq 0.7$	Acceptable
$0.7 > \alpha \geq 0.6$	Questionable
$0.6 > \alpha \geq 0.5$	Poor
$0.5 > \alpha$	Unacceptable

(*George, D., & Mallery, P. (2003). SPSS for Windows step by step: A simple guide and reference. 11.0 update (4th ed.). Boston: Allyn & Bacon.)

From this statistic, given 53 participants, we can see the entire inventory with 11 changed sentence starters out of 36, had an internal consistency of .88 (only .02 away from "Excellent"). However the 11 new ("child") stems by themselves didn't fare as well, letting us know that we won't test with only the child stems but will always use the 36 sentence stems with the child sentence starters embedded. This should give us an accurate result. Also, we plan further research on strengthening the new child-friendly stems.

Results

Above we described our new method for aggregating survey scores into the final "core score." This, combined with the 1.1 million word study which shows what words tend to come up at each developmental level, helps us make a more nuanced decision in the scoring of each sentence stem, a process of triangulation with different kinds of evidence to support a more accurate score. This gives us the data to support the core stage any person is at. (Our preliminary vocabulary research is summarized in the paper in this issue summarizing all STAGES research to date.)

The test was administered verbally to 53 children at their school in Brisbane, and the audio was transcribed. An expert scorer scored the results, which are shown in Figure 3 as frequencies in histograms at both the item level and the survey level.

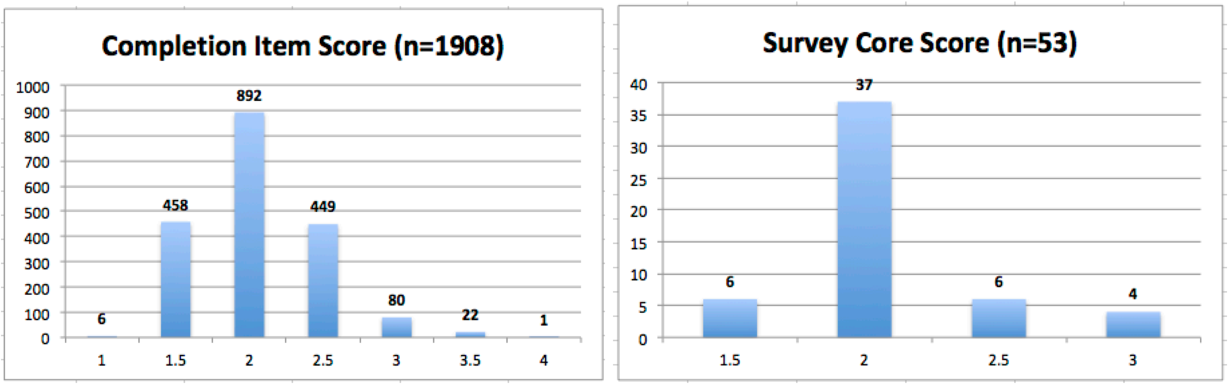

Figure 3. Child Study results: frequency histograms.

From the Survey graph we can note that the vast majority of children scored at 2.0, with a few at 1.5, 2.5, and 3.0. From the completions graph we can see that there are also a few item scores as low as 1.0, and as high as 4.0

O'Fallon continues to analyze this data to derive descriptive accounts of how the children make meaning of various themes (later to be published).

Discussion

Most children at the 1.5 Egocentric level range from the ages of about 18 months old to about the age of 4 years old. The 2.0 Rule Oriented level generally begins around the age of 4, and ranges up through around the ages of twelve or thirteen. The 2.5 Conformist level can range from the approximate ages of 12 or 13 through the age of around 19, but we also have many adults at that age. The 3.0 Expert usually ranges from around the age of 18 or 19 though the mid 20's but can extend far into the 20's and 30's and beyond.

Looking at the ranges of these children who were at about the age 4 ½ through the ages of about 13, we can see a healthy distribution with most of the children expressing at the 2.0 level and six younger children who were old enough to be in school but still represented the 1.5 level. However, we also see that 11 children representing nearly 21% of this population, seem to reach into the 2.5 and 3.0 levels and appear to be more developmentally mature than most children in that age range. There could be many reasons for this, including a developmentally appropriate curriculum for the children.

Summary

We have developed an oral sentence completion test for children. This test has very close to an excellent internal consistency using Cronbach's alpha. We have tested 53 children using this test and that we are now doing qualitative research to uncover descriptions of healthy children at these levels which are mostly populated with healthy children, rather than with compromised adults. This is just a beginning, and we are happy to be on this journey.

Future Research

The next question we are inquiring into is “What are the phenomenological qualities of children at each of these developmental levels?"

To respond to this question we are in the process of doing a qualitative research project. We are categorizing all of the sentence completions at each developmental level into common themes to see if we can locate common identifiers for children at each of these levels.

To date we have done the preliminary categorizations on about 70% of the 1908 sentence completions. We will continue to sift through all of these stems until we have an idea of the themes that describe children at each of these developmental levels This will take some time and will be well worth the effort.

Investigating the Validity of the Ogive Aggregation Method, Including the use of Rasch Analysis, for the Sentence Completion Test and the STAGES Model

Tom Murray[1]

Abstract: This project assesses psychometric aspects of the STAGES sentence completion test (SCT) using data from 740 scored surveys, and some of the analysis applies to all variations of the SCT for ego development (meaning making maturity). The goals of this research project include: (1) to apply item response theory (IRT) and Rasch analysis to determine item-level psychometric properties of the SCT that were previously unaddressed in SCT research; and (2) to further investigate suspected problems with the ogive cutoff method for aggregating item scores in the SCT and propose alternatives. The psychometric analysis includes: within-test item normality, item standard deviations, test length analysis, factor analysis, characteristics of and correlations among each item, overall test strength, and construct levels discrimination. A range of issues with the standard ogive cutoff method are described, and a new item aggregation method is then proposed.

Keywords: Adult ego development, ogive cutoff**,** psychometrics, STAGES, sentence completion test.

Executive Summary

This project assesses certain psychometric aspects of the STAGES sentence completion test (SCT) using data from 740 scored surveys, and some of the analysis applies to all variations of the SCT for ego development (meaning making maturity). The goals of this research project include: (1) to apply item response theory (IRT) and Rasch analysis (a subset of IRT) to determine item-level psychometric properties of the SCT that were previously unaddressed in SCT research; and (2) to further investigate suspected problems with the ogive cutoff method for aggregating item scores in the SCT and propose alternatives.

SOME RIGHTS RESERVED

The paper begins with an overview of the history of the SCT, including Loevinger's original work and variations by Cook-Greuter, Torbert, and O'Fallon. We then describe the STAGES model and assessment in greater detail, highlighting how the model differs from prior SCTs.

We summarize evidence for the psychometric strength of the SCT. Most of the 400+ studies of the SCT were conducted with Loevinger’s WUSCT, but studies of the other variations inevitably replicate results of the general validity characteristics of the test. We summarize prior research on the SCT regarding inter-rater reliability, internal consistency, test-retest reliability, face validity, construct validity, incremental validity, clinical utility, and predictive validity, supporting Westenberg et al.'s conclusion that "findings of over 350 empirical studies generally support critical assumptions underlying the ego development construct" (p. 485).

Specific to the STAGES model, we reference another peer-reviewed paper (O'Fallon et al., 2020) describing a "replication study," which shows that the STAGES scoring method replicates prior (MAP) SCT scoring up to 4.5 Strategist. That paper also summarizes longitudinal data analysis including the upper levels, which shows evidence for the monotonic developmental sequencing of O'Fallon's newly defined highest stages (Metaware Tier).

We next focus on methods used to aggregate the 36 item scores into the total protocol rating (TPR), especially the ogive cutoff method and secondarily the less-used TWS (total weighted score) method. We argue that the ogive method entails a number of drawbacks, including:

1. Lack of empirical support for discontinuous levels
2. No population studies for Bayesian estimates
3. Difficulties estimating extreme values
4. Lower cutoffs confuse development with "shadow" evidence
5. Sensitivity to error
6. TWS misalignment
7. Additional issues with the TWS multipliers
8. Errors in the ogive formula and assumptions

This paper then describes the method and results of our statistical analysis of the 740 STAGES protocols using descriptive statistics, item response theory, and Rasch analysis. Below is a summary of the findings, which hold for levels 2.0 to 6.0, however for the rare extremes of 1.0, 1.5, and 6.5 surveys, there are too few data points for confident conclusions.

1. **Within-test item normality**. A skew and kurtosis analysis shows that scores within each survey are, on average, normally distributed. This does not support the common supposition that the scores’ "bell curve" within surveys would contain more items below the average score than above it.

2. **Item standard deviations**. The average standard deviation of item scores within a survey is remarkably similar across all developmental levels. Thus, the shape of the distribution of the 36 scores within a survey does not change much for individuals at different centers of gravity.

3. **Test length.** A Cronbach-Mesbah analysis (of the Cronbach's alpha score for successively fewer test stems) shows that for a half-item test the reliability is excellent (.95); that with 10 stems, the SCT has very good reliability (.92); and that at 5 stems the reliability is acceptable (.85). This supports any future projects that use surveys with fewer than the 36 items.

4. **Factor analysis**. A factor/component analysis of the data confirms prior findings that the SCT loads on one factor or in other words seems to be measuring a single latent variable.

5. **Characteristics of and correlations among each item**. We show measures of difficulty (mean score) and spread (standard deviation) for each test item to test the assumption that the SCT test items designed to triangulate (parallax) the construct from many life-contexts are generally equivalent (though they will vary in how they function per individual). The results confirmed in the Rasch analysis show that there is some variation among the items, but overall they have similar difficulty and spread. However, the stem "I am..." stands out as being the least highly correlated with all other stems and as having the highest standard deviation. We also show a heat map illustrating the 36x36 item correlation magnitudes.

6. **Overall test strength**. Rasch and IRT analyses confirm that the test is very robust/sound as a psychometric measurement across its entire range. Test reliability and coverage are excellent and the items have good discrimination. Scoring is highly consistent (i.e., good quality) across the items (similar to prior Cronbach's alpha results).

7. **Construct levels discrimination**. The test easily differentiates the 6 person perspectives and, consistent with the model's hierarchical organization of 3 parameters, has more difficulty differentiating between levels at the granularity of 12 levels. The 12 stages defined by the model are relatively evenly spaced along the spectrum, which supports O'Fallon's conjecture that the STAGES model cuts the range into equal slices or provides a consistent "ruler" which is resilient to data collected in future studies from different populations.

New item aggregation method. Given the problems described for the ogive cutoff method, we experimented with a number of alternative methods for aggregating the survey items. Our goals for a new method were:

1. achieve compatibility with the expectation that for a projective test, a person's true "center of gravity" will be evidenced from the higher scores;

2. avoid the problems of the ogive cutoff method and use something more straightforward and with fewer arbitrary parameters;

3. to minimize the differences between the new method and the prior ogive method, so that we would not have to alter the established interpretation of each level (i.e., to remain consistent with how a "3.5/Achiever" total score is understood in the field).

The methods we tested are described in the paper. In the end we chose taking the mean of the top 6 scores in the survey (or the top 1/6th of the scores if the survey has other than 36 items). This is modified slightly to produce a value that is, on average, close to the original ogive method by using the formula: (1.2*AveOfTop6)-1. We call this value the Core Stage (for continuity with prior articles, note that we originally called it the Focal Score). STAGES International will begin to phase in this method, firstly alongside the ogive method, before eventually replacing it over the next year or two.

The Core Stage regards a continuous value. The benefits of this method include that the value is not sensitive to small perturbations or errors around cutoff boundaries and that it is easily extended to different test lengths without revising the set of cutoffs. Another benefit of this method is that it does not confuse shadow crashes with low complexity/maturity, which is the case with the ogive method, and thus can be used for scoring children (which O'Fallon has begun doing).

The revised scoring system will show several measures in addition to the Core Stage: the average (across all stems); the bottom score (the average of the bottom 6 related to a "shadow score" for adults); and *Spread* – the spread score is the Core Stage minus the bottom score, which indicates the range of values in the survey.

The final section of the report discusses future work and limitations, which largely pertain to available data.

The STAGES framework will be gradually shifted to the new Core Stage method. We remain agnostic regarding whether other SCT frameworks should adopt this method or any alternative to the ogive method, which has been performing well enough over the years and represents the default standard, and the effort to adopt a new method may well outweigh any benefits. The benefits of changing are greater for the STAGES model vs. other SCT variations, because others use a fixed set of stems while STAGES allows creating valid surveys with new stems of any length – which would require ongoing adjustment of cutoff values that can only be performed in arbitrary ways. In addition, automated computer scoring exists for the STAGES model (see www.stagelens.com), which means the SCT will become more practical to use for large-scale research where the validity of methods is more critical.

Introduction and Background

Motivations and Research Goals

The sentence completion test (SCT) for adult development, originally created by Jane Loevinger and later extended by Susanne Cook-Greuter, William Torbert, and Terri O'Fallon (each developing different variations), is arguably the most thoroughly researched, validated, and used developmental instrument in adult psychology. Loevinger used the term "ego development" for this "holistic" view of personality and cognition that "[sees] behaviors in terms of meaning or purposes" (Loevinger 1970, p. 3).[2] Ego development has been described using concepts including leadership maturity, perspective-taking complexity, sophistication of world-view consciousness, and "wisdom skills" and has substantial overlap with the construct of meaning-making maturity described in Kegan's construct developmental theory (Kegan, 1998). Kegan describes it as a "consistency in the structure, or order of complexity, of one's meaning-making (i.e. how one thinks)" (1998, p. 55) about the relationships between self, other, and the world (intrapersonal, interpersonal, and cognitive in Kegan's terms; and "I/we/it" in terms of Wilber's Integral Theory (1995)).

Loevinger's theory of ego development was intricately linked to her assessment instrument called the Washington University Sentence Completion Test (WUSCT; Hy & Loevinger, 1989; Loevinger & Wessler, 1970). The literature on the SCT is extensive, and according to an overview by Westenberg et al. (2004), the SCT test has robust psychometric properties with "indicated excellent reliability, construct validity, and clinical utility" (p. 596). They further state that, "findings of over 350 empirical studies generally support critical assumptions underlying the ego development construct" (p. 485), and dozens more studies have followed since 2004 (Torbert, 2009).

The SCT is a "projective" test in which subjects complete sentence starters and respond freely without a need to produce a "correct" or superior answer – which the theory claims affords the test analyst a deeper view into tacit or unconscious psychological traits. The standard SCT has 36 sentence starters ("stems") such as "Raising a family…" and "When people are helpless..." which the test taker completes (e.g., "…is a joy", "…they get taken advantage of") and are rated independently. Sentence completions vary from a few words (even one word) to full paragraphs (and rarely multiple paragraphs). Rather than a simple sum or mean of the item scores, the TPR score uses a more complex cutoff method called the "ogive method" for reasons we describe later. This converts a complex continuous score into one of a set of discrete categories (levels or stages: 8 for Loevinger's model, 9 for Cook-Greuter's and Torbert's models, and 12 for O'Fallon's model).

Despite the depth and breadth of the SCT instrument and its psychometric strength, assessments of its validity all (as far as we can tell) have used "classical test theory" and focused on the validity of the assessment as a whole (i.e., the TPR). There has been little focus on its per-item psychometric properties besides the internal consistency of the items (the Cronbach’s alpha measure). Although it is still widely used due to its robustness in most contexts, classical test theory has been superseded in the last half century by item response theory (IRT) psychometric methods, which include a deeper analysis at the item level of the test. The present study applies IRT (and Rasch analysis) to SCT data to gain insights about the properties of the SCT. More importantly, the ogive method for aggregating item scores has been largely taken for granted and simply re-used in the hundreds of studies using the SCT, despite some limitations of the ogive method.

---

[2] Browning (1987, p. 113) describes ego development in terms of "a series of developmental stages that are assumed to form a hierarchical continuum and to occur in an invariant sequence…[that describes a] person's customary organizing frame of reference, which involves…an increasingly complex synthesis of impulse control, conscious preoccupations, cognitive complexity, and interpersonal style."

In this paper we describe limitations and some potentially serious problems with the ogive method and suggest an alternative method for aggregating the test items. One problem with the ogive or any cutoff method, or indeed any method that forces continuous phenomena into discrete values, is that they are sensitive to small variations and noise near the cutoff points. For example, a cutoff rule that assigns a TPR of "achiever" if 10 or more of the 36 items scores are at or above the achiever level is fragile for surveys that have 9, 10, or 11 such scores. In this range, if the score had just one or two more or fewer items at the achiever level due to rater error or inter-rater variation or an arbitrary glitch in the subject’s thinking when taking the test, the score would jump an entire developmental level.

These issues are unlikely to impact the vast majority of the hundreds of published studies that use the SCT method, especially those with medium to large sample sizes. Small "random" variations that cause the TPR to "flip" up or down a level will "wash out" in statistical aggregations. Such issues might be more important for case studies and other small-N studies, where a single level difference in a couple of TPR scores could change the conclusions. Beginning with Cook-Greuter and continuing with Torbert and O'Fallon, the SCT is increasingly used to provide developmental scoring and coaching/consulting advice to individuals (something Loevinger strictly avoided). It must be said that all three of these researcher/practitioners and their associates are careful not to allow the use of the SCT for high-stakes assessment decisions such as hiring and firing (to the extent possible) but instead use it as a tool for self-reflection and personal growth (for individuals but also for teams and organizations). Nonetheless, the sensitivity of the cutoff method to perturbations is concerning since the characteristics of, and thus the advice given for, each developmental level is distinct (i.e. adjacent levels such as Expert and Achiever differ significantly along many dimensions).

The research in this paper was executed in an attempt to validate and improve O'Fallon's STAGES variation of the ego development theory and assessment, yet some of our conclusions concern the entire SCT lineage (other results apply only for the STAGES model). STAGES represents the most recently developed model in this lineage and differs from others by proposing a small set of underlying "drivers" or parameters (i.e., underlying mechanisms) purported to explain most or all of the surface features of the spectrum of meaning-making development. The research goals addressed in this report include:

- To further investigate suspected problems with the ogive cutoff method for aggregating item scores and to propose alternatives;

- To apply IRT and Rasch modeling to determine psychometric aspects of the STAGES SCT that were previously unaddressed in SCT research, including:
    - An item-based determination of overall test strength (including factor analysis and reliability);
    - Item-based analysis to identify items that behave differently than others or have sensitivity to particular regions of the developmental spectrum;
    - Test-length analysis to determine the validity of shorter versions of the SCT;
    - Scale uniformity and resolution to determine whether the categories (stages) in the model are relatively uniform and well differentiated;

- To assess other statistical properties of the measurement, including the skew and kurtosis metrics, indicating whether the spread of items in the surveys is normally distributed (on average).

Project Beginnings

There were two initial motivations for this project. First, O'Fallon's statisticians suspected some fundamental errors in the assumptions behind the ogive cutoff method for aggregating the (36) response scores used to produce the total survey score (TPR) traditionally used in Loevinger-lineage sentence completion tests. One goal was to clarify these issues and identify alternatives to the ogive method.

Second, the main alternative framework to STAGES and other SCTs include the Lectica assessments (based on hierarchical complexity theory (HCT), see Commons et al., Dawson et al., and Fischer et al.), and research in this lineage uses Rasch modeling for evaluating psychometric validity.[3] Rasch analysis is considered by most to be a subset of IRT methods, and IRT methods represent a more robust and modern set of methods than the classical test methods Loevinger chose over 30 years ago and continue to be used with the SCT. One of our goals was to upgrade methods to more modern techniques and also to determine whether IRT can shed light on how to replace the ogive aggregation method.

Over the course of this research, Murray engaged the assistance of many professional statisticians/psychometricians. Each result shown here was read and approved by at least two of these experts, although consultant reviews regarded checking that the methodology fit the context and conclusions and none checked the actual data processing steps (i.e., the author is wholly responsible for any such errors, and none of these consultants can be said to have vetted and agreed with this report in its entirety and full detail). We would like to thank the following for their help at various stages of the project: Matt Johnson – Columbia University faculty in psychometrics and statistics research; Trevor Bond – faculty at James Cook University and lead author of *Applying the Rasch model: Fundamental measurement in the human sciences* (Bond & Fox, 2001; Bond, 1994); Bob Dolan – a psychometrician in the field of educational technology who has worked for several publishing and research companies; Mike Linacre – psychometrician and developer of the WINSTEPS software package for Rasch analysis; Larry Price – Texas State University Professor and author of *Psychometric Methods: Theory into Practice*; and Moni Blazej Neradilek and Nayak Polissar – lead statisticians at Mountain-Whisper-Light Statistics, the company O'Fallon uses for much of her work on the STAGES model.

Part of this work was funded by the Developmental Research Institute (DRI), a registered non-profit research organization founded originally by Terri O'Fallon, Suzanne Cook-Greuter, and others, which is currently lead by O'Fallon, John Kesler, Venita Ramirez, and Judy Stevens Long. Although the mission of DRI is to further research adult developmental assessment and theory in general, we acknowledge that most of its board members have close affiliations with

---

[3] Kegan's model is also predominant in the field, but its assessment method, the subject-object interview, is much less frequently used, because it is much more time consuming to both administer and score.

O'Fallon, as does the author, and that there may be some unintentional bias toward the STAGES model in the reported research.

SCT History

Below we describe the evolution of the SCT and compare its various versions to illustrate their significant similarities for two reasons: to argue that (1) many conclusions made in this study with STAGES assessment data will apply to other SCTs; and (2) prior research using the WUSCT, which constitutes the vast majority of the roughly 400 studies on the SCT, applies to the other SCTs.

The SCT for adult development originally developed by Jane Loevinger was later extended by Cook-Greuter and associates, Torbert and associates, and O'Fallon and associates. Although Loevinger remained an academic, the others branched out of academia to start companies that engage in developmental assessments, organizational consulting, and consultant trainings (Torbert works both in academia and industry consulting). Cook-Greuter was a student of Loevinger and Torbert was one of her dissertation advisors, and both Torbert and O'Fallon were at various times working as business colleagues of Cook-Greuter, who is currently a principal at Vertical Development Academy; Torbert worked at Harthill Consulting for 20 years and then founded Global Leadership Associates with Elaine Herdman-Barker; and O'Fallon is co-founder at STAGES International. All four of these organizations continue to work with the SCT and, as far as we know, represent the only organizations that currently provide scoring of and certification in the SCT. Vertical Development Academy calls their SCT "MAP," Harthill Consulting calls theirs LDP, Global Leadership Associates calls theirs GLP, and STAGES International calls theirs STAGES (Torber et al. 2009, 2014 describes validity research on MPA, GLP, LDP).

Loevinger's model and assessment was extended in three ways by those that followed her: (1) the underlying psychological theory evolved, (2) the STC itself was altered regarding the number and selection of stems, and (3) the analysis method defined in a "scoring manual" also evolved.

In terms of the SCT instrument, MAP and the "general protocol" of STAGES use 36 stems, following Loevinger, while LDP and GLP contain as few as 24 stems. Although each SCT variation has altered some of Loevinger’s original sentence stems, all share at least 75% of the stems with the original WUSCT and with each other.[4] Although Loevinger and other researchers using her methods have validated and used an 18-item ("split half") variation of the SCT (see Novy & Francis, 1992; Holt, 1980), the short version is not used for the individual scoring currently done by the others. However, O'Fallon has been developing and validating "specialty" protocols with both varied lengths and 6 or more stems from the "generic" SCT replaced by stems focused on specific themes (e.g., love, money, spirituality, etc.). The research reported here utilizes the STAGES generic protocol.

---

[4] See Torbert 2014 for a detailed comparison of the MAP, GLP, and LDP variations of the SCT. Torbert and Cook-Greuter modified the WUSCT stems to "omit a number of gender-based items and, includes work or leadership-related stems" (Torbert & Livne-Tarandach, 2009).

In terms of the theoretical model, Cook-Greuter extended Loevinger's system by differentiating two stages (which she called Construct Aware and Unitive) within Loevinger's final stage (a model also used by Torbert and associates). O'Fallon's research has taken this progression further by differentiating four stages (5.0, 5.5, 6.0, and 6.5) within the same late-stage territory. O'Fallon also differentiated the Conformist (or Diplomat) level into two levels based on theoretical principles along with her other modifications. (Thus, STAGES defines 12 levels, MAP/GLP/LDP defines 9, and WUSCT defines 8). All of the scoring methods have procedures for marking a developmental stage as early, middle, or late, so the potential number of "strata" or sub-stages has a finer resolution. Although the early/late distinction is used in qualitative consulting with the client, for the research reported here all score data regards the per-stage resolution (i.e., early/late designations are not used).

Cook-Greuter attempted to address her notion that Loevinger's model was "lacking an underlying structural logic" (1999, p. 76) by linking the sequence of stages to "person perspectives" (p. 77) (e.g., first-person perspective, second-person perspective, etc., sometimes referred to as worldviews). This strengthens the ego development construct from a "soft" description-based construct towards a "hard" model-based construct, which provided a coherent theory that could support the entire developmental trajectory using a single concept (pp. 72–76). However, this change was applied only to the conceptual description of the model rather than to the scoring methodology. O'Fallon extends this innovation by more fully integrating the concept of person-perspectives into both the theory and the scoring procedure.

A scorer using the WUSCT, MAP, GLP, or LDP tests consults a scoring manual comprising thousands of example sentence completions organized by stem, level, and theme. The scorer attempts to match a sentence completion with an example or thematic group of examples, and if no match can be found, more general heuristics defined for each level (independent of stem) are used. Westenberg et al. (2004a, p. 485) note that "the scoring manual for the [WUSCT] consists of over 2000 response categories...about 80 response categories for each of the [...] items." The 300+ page scoring manuals used for the MAP, GLP, and LDP contain 16,000+ examples, and training to score from the requires many months and close supervision until acceptable inter-rater reliability is achieved (vs. a maser scorer). For the two highest levels added by Cook-Greuter, scoring relies more on heuristics than exemplars (the method is used for the MAP, GLP, and LDP).

While all the other methods follow Loevinger in using an exemplar-based scoring method, the STAGES model differs by basing its model and scoring method on an underlying quasi-causal model that applies a repeating pattern using a small set of foundational parameters. The scoring procedure (the manual) is thus stem-independent and does not rely on exemplars but on underlying language properties and structures.

The STAGES Model

Although the example-matching method was chosen by Loevinger, it entails drawbacks. Because human language is diverse and expressive and there are so many ways that an individual at level X could respond to stem Y, it is quite time consuming to add new levels or sentence starters, which requires the collection and validation of excessive amounts of data to define exemplars and heuristic rules (e.g., see Minard, 2009; Cook-Greuter (1999)). For scorers, matching to exemplars can be tedious and time consuming, and these issues motivated O'Fallon to develop an alternative theoretical and scoring framework. Following years of scoring experience using the MAP framework and using insights sourced in Ken Wilber's Integral Theory (the AQAL model, 1995), O'Fallon proposed that a small set of underlying parameters could be used to explain (and score) the entire developmental sequence. This idea, in its final form after several iterations, has proven to be a valid method to understand and assess ego development.

STAGES defines 12 developmental levels (stages) in three tiers (Concrete, Subtle, and Metaware) with each four levels each. The levels in each tier progress through a sequence of four learning-and-acting orientations: Receptive, Active, Reciprocal, and Interpenetrative. The sequence is also defined as progressing through 6 "person perspectives," each of which has an early (passively oriented) and late (actively oriented) phase. The STAGES are thus identified as 1.0, 1.5, 2.0, 2.5...6.5, where the "1." to "6." reflect the six person perspectives and the ".0" and ".5" reflect the early and late phases of each person’s perspective. Appendix 2 contains figures illustrating the STAGES levels, and for a detailed description of the STAGES model, see other articles in this journal special issue and material at stagesinternational.com.

Because it does not rely on exemplars but rather on underlying language properties, it is much easier to create modifications to the STAGES SCT compared to the other variations. The same scoring heuristics are used regardless of the sentence stem, and new stems can be added to the SCT without the need to conduct extensive research into how people might respond to the prompt. O'Fallon has developed several "specialty protocols" using alternate sentence stems, and in each case the internal consistency of the SCT remains high. In addition, because it is based on language properties rather than specific exemplars, STAGES is less susceptible to drifts in word meanings over generations and should be easier to apply to multiple languages. Finally, using generic theory-based scoring rules allows the method to be extended beyond the SCT to preform developmental analysis on arbitrary texts such as reflective essays, story narratives, speeches, and books (O'Fallon has applied the method to such texts, but we lack validity studies on these novel applications). (Note that, despite the notes above on the flexibility of the STAGES for creating alternative SCTs, the studies reported in this paper regard the standard-length "general" protocol, which has significant overlap with the stems of the other SCT variations.)

STAGES is also a fully "hard" stage theory in that its stage boundaries are determined by theoretical rather than empirical or practical considerations. The number of stages and their boundary lines changed several times during Loevinger's work, and Cook-Greuter made additional modifications based on empirical or pragmatic reasoning. Loevinger and Cook-Greuter explicitly chose a data-driven rather than theory-driven foundation for the ego development model, meaning they wanted the model to be driven by real observations rather than by assumptions imposed by an abstract theory. It is however difficult to claim that one has the correct or best stage definitions under such circumstances.

Data-driven methods are best for new and emerging theories, but at some point theory-driven approaches become feasible when enough is known to propose a stable set of underlying mechanisms that give rise to surface features of the data (the neo-Piagetian developmental models of Commons and Fisher are also theory driven). The number, sequence, and boundary conditions of the STAGES model directly originate from its theoretical assumptions and will not change any time soon. Of course, science evolves through an iterative dance between theory (ideas) and evidence, and even set-in-stone theories must be occasionally re-evaluated in light of new data. O'Fallon readily acknowledges that a day will come when STAGES is superseded by another model – personal communication.[5]

The above paragraphs describe how STAGES differs from other SCT variations, including its purported benefits. Although this allows coordinating the results of our study with other SCT variations, it is important to note that for the purposes of the study reported here, STAGES is largely similar to its predecessors.

The first proof of this is argued in detail in "The Validation of a Novel Method for Assessing Developmental Stages of Meaning-Making Across the Life Span" (O'Fallon et al., 2020), which reports on a "replication study" of its concurrent validity showing that, for stages up to 4.5/Strategist, scoring with the STAGES scoring methodology correlates exceptionally well with Cook-Greuter's MAP method (and presumably the other SCT variations which are more similar to MAP). For stages above 4.5/Strategist, the definitions of levels diverge too much and there is insufficient data available to perform a proper comparison. However, from Cook-Greuter (2013), we can estimate that approximately 2% of the population or 7% of professionals are above the 4.5 level, so the replication results apply to the majority of people.

Second, it can be argued that the SCT has strong reliability as a methodology regardless of the mentioned variations.[6] This was reported in "The STAGES Specialty Inventories: Robustness to Variations in Sentence Stems," where O'Fallon created about six specialty protocols with alternative sentence stems. These all show high internal consistency via the Cronbach's alpha measurement, indicating that the SCT method is robust over many possible sentence stems (assuming they are rationally designed). In addition, as illustrated later in this paper using a "Cronbach-Mesbah curve," the SCT continues to have strong consistency even for 10 stems (.92), and even at 5 stems the metric is good (.85). In addition, the IRT and Rasch analysis reported later shows that all the 36 stems but one are strongly correlated with each other.

This all indicates that the SCT is a strong and valid methodology regardless of its variations and that certain results from one variation should be applicable to others. This claim weakens for developmental levels at the upper and lower extremes where there is less empirical data and more tentative theoretical understanding, but we do not yet have a sense regarding how much it weakens.

---

[5] We should also note that, because the scoring rules (manuals) are different, the territory for each level defined by the STAGES model need not map *exactly* onto the same territory in the prior models. Our understanding of the psychological and cognitive characteristics of each developmental level contains many aspects (e.g. ability to utilize to feedback, use of either-or vs. both-and language, and how past and future are conceived), and persons identified at level X in STAGES may, on average, have slightly different characteristics vs. persons identified at that same stage in another model. What *has* been empirically demonstrated (O'Fallon et al., 2020) is that, with all of these characteristics taken together as a whole to describe each ego development level, the STAGES model tracks very well with the other models (up through 4.5/Strategist).

[6] Statistical reliability refers to the consistency of a measure, i.e. whether it produces similar results under consistent (accurate, reproducible, and consistent) from one testing occasion to another, having acceptably small random errors. Overall reliability can include inter-rater reliability, test-retest reliability, and internal consistency.

Prior SCT validations

The literature on the SCT is extensive and includes over 40 years of meta-analyses and critical overviews, substantially supporting its validity and usefulness (see Cohn & Westenberg, 2004; Manners & Durkin, 2001; Holt, 1980; Novy & Francis, 1992; Jespersen et al., 2013; Westenberg et al., 200b; Forman, 2010). The paper "Sentence completion assessments for ego development, meaning-making, and wisdom maturity, including STAGES" (Murray, 2017) contains a lengthy summary of such studies, illustrating the validity and reliability of the SCT and confirming Westenberg et al.'s conclusion that "findings of over 350 empirical studies generally support critical assumptions underlying the ego development construct" (p. 485).

Blumentritt (2011, p. 153) says that "more than 1,000 articles and book chapters have been published examining nearly every conceivable aspect of the construct and measurement of ego development," overall showing "substantial support" for the theory and measurement. Most of these studies are based on the WUSCT, but some use the MAP/GLP/LDP variations. For the reasons given above, we claim that these results apply to STAGES as well, and results of the meta-analyses include:

- "Psychometric studies of the WUSCT…invariably report high levels of inter-rater reliability" (Westenberg et al., 2004a, p. 603; and see Torbert & Livne-Tarandach, 2009 for strong results on the MAP, GLP, and LDP; and O'Fallon et al., 2020 for strong IRR on STAGES).

- "The WUSCT [displays] high internal consistency: Most studies report a Cronbach's alpha of .90 or higher" (Westenberg et al., 2004b, p. 693; and see Torbert & Livne-Tarandach, 2009 for strong results on the MAP, GLP, and LDP; and later in this paper for strong internal consistency in STAGES).

- "In terms of test–retest reliability, when sufficient time is allowed between the two tests to allow for motivational effects, significant correlations have been found between test and retest scores" (Manners & Durkin, 2011, p. 545).

- "The face validity of the SCT is demonstrated by the sheer fact that it has been used in more than 300 research studies [including] such diverse topics as parenting behaviors, managerial effectiveness, and the effects of meditation on recidivism rates" (Phaffenberger, 2011, p. 10).

- The SCT has "excellent reliability, construct validity, and clinical utility" (Westenberg et al., 2004a, p. 596).

- Longitudinal studies have confirmed the sequential invariance of the developmental steps (i.e., no stage can be skipped) (Loevinger, 1998).

- The SCT has incremental validity over IQ and SES measurements (e.g., Browning, 1987; Cohn & Westenberg, 2004);

- The SCT has proved applicable in different countries, cultures, and languages (see Carlson & Westenberg, 1998).

- Although there have been fewer studies on the predictive validity of the SCT, Vincent notes that "a growing body of studies is showing associations between increasing consciousness development and better leadership performance and organizational outcomes" and cites a substantial 21 articles in this regard (2015, p. 2). Other indications of predictive and external validity can be found in (Torbert, 2014; McCauly et al., 2006; and Harris, 2005).

Torbert (2014) summarizes a number of studies on the MAP, GLP, and LDP instruments that arose after the WUSCT.

Our study adds to these findings about the SCT (confirming a few of them) and focuses on two areas that have been under-researched: item-level statistics and methods for aggregating the SCT items into the overall score.

The Ogive and TWS Aggregation Methods

How to calculate the overall score of the SCT turns out to be a complex question. One reason is that participants are expected to exhibit a range of developmental levels in their answers. In a projective test the subject is responding freely, rather than trying to score as high as she can, and it is actually viewed as more healthy or well-rounded when responses range over at least 3 or 4 levels (however for individuals at low developmental levels there is less room to range over). A survey with all items within a tight range of 2-3 levels is not only unusual, but it is considered possible evidence for a rigid personality style.

Most psychometric tests take the simple sum or mean over their items, although sometimes the items are weighted according to difficulty or information power. This is however not a particularly satisfying method for the SCT. For a projective test where the subject is not attempting to "answer" or "solve" anything, some items may demonstrate the subject's true competence while others may naturally be more "off the cuff," meaning short and simple, playfully carefree or irreverent, or even impulsive or unreflective "outbursts." Our intuitive understanding of the construct and the test seems to demand that we focus on the highest scores that the subject produces.

For example, if someone attains a score of, say, 4.5/Strategist level on 8 of the 36 items, then they must have a strategist level of meaning-making, because according to both the theory and empirical evidence, it is difficult to "fake" or "guess" items to produce a score higher than one’s actual developmental level (Redmore, 1976). Whether the other scores on the test are near 4.0/Pluralist or 2.5/Conformist does not change the fact that they seem to have achieved a 4.5 developmental level. However, having the rest of the scores at 4.0 vs. 2.5 *does* strongly affect the average or sum of the items. One of the justifications for using the SCT cutoff method is that it prioritizes higher scores (or more accurately scores that are rarer within the population).

Within the Loevinger tradition there are two established methods for aggregating the 36 SCT items to obtain an overall score for the survey: the ogive and the TWS. The most commonly used by far is a cutoff method called the ogive method (yielding the total protocol rating, or TPR, sometimes called "center of gravity"). In the ogive method, one follows a procedure to check each level in turn to determine whether there are sufficient scores at or above that level. The ogive cutoff method essentially "throws out" data beyond the cutoff. According to Cook-Greuter (1999, p. 222), "One thus rates a test at the highest stage that is exhibited if enough evidence at that stage is present and not enough at the next higher level." The cutoff number varies over the levels, as detailed in Appendix 1.

Holt et al. describe Loevinger's reasoning: "Human development has this odd, psychometrically inconvenient property of maintaining the potentiality to respond on many lower levels after one has, in a certain sense, left them behind. The ogive rules respect this peculiarity and allow for it" (Holt et al., 1980, p. 917). Cook-Greuter says the ogive (or center of gravity score) "is assumed to reflect a person's most ego-syntonic and habitual frame of reference or preferred mode of responding to life."

The other aggregation method which is usually calculated along with the ogive, but is much less frequently used regards the total weighted score (TWS) method,[7] which sums the scores over the 36 items and returns an integer typically in the 300-600 range. The formula used for STAGES is: (f_1.0 * 2) + (f_1.5 * 3) + (f_2.0 * 4) +...+ (f_6.5 * 13), where for example f_1.5 is the count (frequency) of completions scored at 1.5.[8] There are slight variations on the constants used in this formula for different frameworks.

The ogive method is preferred because Loevinger believed that its categorical result is more meaningful and has more construct validity compared to the TWS method. The theoretical model, the scoring manual, and the scores assigned to individual completions are all based on a sequence of discrete categories.[9] Researchers in the psychological and social sciences almost universally acknowledge that psychological phenomena are complex and that using discrete categories involves substantial simplification which is thus performed for practical reasons. There is considerable debate within the developmental psychology community regarding whether development occurs continuously or in spurts that create quasi-discrete levels or stages (see Dawson et al., 2005 for some evidence of discrete spurts). However, no research has tested whether the construct of ego development actually grows continuously or in spurts, so the use of categories rather than a continuous scale represents a practical and/or theoretical decision but is unsupported from an empirical perspective.

---

[7] The "weighted" in TWS is actually misleading, as the score is very close to a linear sum of the 36 scores. The term weighted is probably an artifact of the fact that originally the data was represented using frequency vectors, i.e., for a system ranging over 10 levels (as in MAP) the data had 10 values, each showing the count of scores at that value. The method was used prior to personal computers, and saving 10 numbers was easier than saving 36 numbers (the values for each completion). Unfortunately, because of this, archived data from most surveys in this tradition is missing important per-item information. We know that, for example, a survey had 14 items at the "Expert" level, but we don't know *which* of the 36 items scored at the Expert level. This makes certain types of analysis, including IRT analysis, impossible with such archived data.

[8] Note that the Ogive cutoff method, which returns a category (ordinal) value, must be implemented with a procedure (i.e. checking the cutoff at each level in sequence, and if it is not satisfied moving to the next level...), whereas the TWS method is implemented with an algebraic equation.

[9] Loevinger's scoring manual does allow for assigning "borderline" scores; and the manuals developed by Cook-Greuter, Torbert, and O'Fallon, allow for the refinement of the stage-based scoring to specify whether an item is early, central, or late within a stage.

Although the discrete ogive measurement is predominantly used, the continuous TWS measurement is sometimes used for comparative, pre-post, or longitudinal studies since it is more sensitive to small changes. It can require years for individuals to change one developmental level if they do at all.

The ogive cutoff values are theoretically or conceptually inspired by Bayesian probabilistic principles (Lee, 2012) and concern how much information is needed to conclude that a person is at level X with for example 95% confidence.[10] (95% is usually chosen as the confidence factor to use.)

As noted in Appendix 1, the cutoff procedure begins with the top level and proceeds to check each lower level until 3.0/Expert, at which point it switches to testing the lowest level and works its way up to 2.5/Conformist (the same method is used for Loevinger and Cook-Greuter with slightly different stage sequences compared to STAGES). This follows the principle of first checking for the least likely possibilities. The 2.5/Conformist level was determined to be the "average" or most frequent level (the "prior probability" in Bayesian terms), and thus the final step of the procedure selects 2.5 as the default "if there is not sufficient evidence for any of the other levels." It is the "default" level i.e. the one guessed given no other information.

Note that in actual scoring for clients according to both the STAGES method and the earlier WUSCT and MAP methods, the analyst can adjust the final total score based on global subjectively determined factors. An ogive score, especially one on the edge of a cutoff value, can thus be tweaked up or down a level given sufficient evidence from considering the big picture over all stems (remember that each stem is scored by itself without influence of other stems or the whole). Our analysis estimates that this TPR adjustment is performed less than 10% of the time.

Problems with Ogive and TWS Aggregation Methods

Here we arrive at one of the main purposes of our present study. The ogive method has several drawbacks and even seems to include some errors within the assumptions used to determine the cutoff numbers. Given the large number of studies using the SCT, the ogive method for accumulating items is surprisingly rarely if ever questioned or analyzed. One reason for this may concern the large number of studies in the field, as one wants to build upon and be able to compare results with prior studies, and questioning foundational assumptions of a well-established framework might appear counterproductive to many research goals.

---

[10] Based on the idea that, as in medical diagnosis, the rarer a symptom, the greater its predictive power.

We will mention problems with cutoff methods and problems specific to the ogive cutoff method, specifically:

1. Lack of empirical support for discontinuous levels
2. No population studies for Bayesian estimates.
3. Difficulties estimating extreme values
4. Lower cutoffs confuse development with "shadow" evidence
5. Sensitivity to error
6. TWS misalignment
7. Additional issues with the TWS multipliers
8. Errors in the ogive formula and assumptions

Lack of empirical support for discontinuous levels. The cutoff method forces survey scores into discrete categories, but there is no evidence that ego development grows in discontinuous spurts. One of the leading researchers using the SCT notes:

> The ogive rules are ingenious procrustean devices to make gradual transitions look like phase changes, translating continuity into discontinuous types. Naturally, therefore, at the borderlines, scoring gets much more unreliable... Furthermore, since these rules put special emphasis on the few most extreme scores, [the total scores] become even less reliable the farther we get from the center of the distribution of the population. (Holt, 1980, p. 918)

No population studies for Bayesian estimates. A problem with the cutoff method is that, based on Bayesian probability concepts, it makes assumptions about the overall population, which entails three problems:

1. In fact there are no large scale (population-scale) studies using the SCT (in part because it is time-consuming and thus expensive to score). Loevinger's estimate of Conformist as being the average (i.e., the prior probability) was an educated guess based on a number of studies (each with subjects in the hundreds at most), however many of these studies regarded populations such as pregnant mothers, prison populations, and others with below-professional educational or socioeconomic status. This may be a reasonable guess for the average U.S. population, but the modern uses for the SCT predominantly concern professional or self-improvement contexts where "leadership skills" and "self-reflection skills" are considered important. Articles by Cook-Greuter, Torbert, and O'Fallon have tried to estimate the percentages of each developmental level within specific populations such as the general population, college-educated, professionals (managers), and consultants (see Cook-Greuter, 2002; Torbert & Livne-Tarandach, 2009), but none of these are based on random samplings of populations.

2. Within any specific population, the base estimates ("prior probabilities") will differ, and thus the Bayesian assumptions differ and therefore the cutoffs should ideally be modified, but this is never performed. In practice, the lower and middle cutoff numbers, including the procedural "switch-over" after 3.0/Expert from checking downward to checking upward, are never modified. This is probably because one desires results to use standard methods and to be comparable with past research in the field. In addition, gathering

enough data in any sub-population to determine the proper new cutoffs is usually prohibitively difficult.

3. Several sources indicate that the population as a whole becomes more sophisticated over time, suggesting that the base rates should evolve over the decades. This factor is also ignored when retaining standard ogive cutoffs.

Difficulties estimating extreme values. The Bayes-based method for determining the ogive cutoffs (details in Appendix 1) is particularly problematic near the upper and lower extremes or for the rarest scores. Loevinger says, "The rule is not helpful at extreme ratings. However, the number of cases per category at the extremes is so small that theory or intuition is a more reliable guide" (p. 121). Cook-Greuter (1999) says:

> Employing Bayes' theorem for the problem of determining cut-off numbers at the high-end was a creative move by Loevinger at the original time...On the other hand, I found Bayesian reasoning alone inappropriate at the upper end...Therefore, I felt that cut-off numbers needed to be related to the actual number of post-autonomous responses observed...rather than merely based on probabilistic calculations. (p. 228)

Cook-Greuter chose stricter cutoff criteria for the top levels compared to Loevinger and notes that the question of "how many pieces of evidence one requires to draw a conclusion, is a necessary step. It is also arbitrary – arbitrary not in the sense of random or capricious, but in the sense of arbitrated, reasoned, deliberated" (p. 224).

The populations of interest in many contemporary assessment projects are in or near what Loevinger considered the "extreme" of the upper end, and thus these problems are central to modern assessments rather than being relinquished to rare occurrences. Cook-Greuter and associates have recently adjusted their cutoff values and no longer rely on Bayesian reasoning (personal communication) but continue to use a similar cutoff scheme, which is thus expected to include most of the issues mentioned here. When adding three new levels to the scheme for the STAGES model, O'Fallon had to take an educated guess for the cutoff numbers of these new levels (each of which split a prior level in half).

Most statistical metrics involve some quasi-arbitrary parameter or parameters (e.g., when using p-values to estimate statistical significance, the significance cutoff alpha is chosen as 5% or 1%, etc.). However, the degree of arbitrariness in the ogive method is considerable given the methods for determining the cutoffs and the fact that there are at least as many such arbitrary parameters in the method as there are levels.

Lower cutoffs confuse development with "shadow" evidence. The scoring rules, including the examples given in the scoring manuals used for WUSCT and MAP, seem to confuse the immature development of ego with "shadow-crashes" or momentary regressions to lower ego levels that may be triggered based on the subject of the stem. Because the levels 1.0/Impulsive and 1.5/Opportunist are "rare" in normal adult populations, they are checked before 2.0/Rule-oriented and 2.5/Conformist in the ogive rules (see Appendix 1). A person needs only 7 of the 36 stems rated at 1.0, 1.5, or 2.0 to have their center of gravity (TPR assigned to those levels respectively. Achieving such a low rating can result from a simplistic one-word answer but it can also result from a seemingly narcissistic or impulsive answer, including the use of vulgarity or mentioning of violence. We argue that the scoring method confuses actual level of development with "shadow crash" phenomena for lower-level responses.

For example, a person may have 19 stems at 3.5/Achiever yet will achieve an ogive score of 2.0/Rule-based if they have only 7 stems at 2.0 or lower., and such a person's center of gravity should clearly be closer to 3.5 than 2.0. Because there are very few people with a center of gravity below 2.5 in the populations that currently use the SCT, this problem has not been salient, however one area where it is limiting regards studying children. O'Fallon wants to use the STAGES model (and has already collected data) for pre-adult populations, and in such cases one desires a more reliable measure of ego development that is not conflating emotional outbursts or "triggered" responses with simply lower levels of ego development (perspective taking).

These problems of conflating maturity with shadow in the lower levels represent an additional reason for transitioning from the cutoff system. This suggests having separate measurements for developmental level (e.g., a sum or average score like the TWS) vs. a shadow-related measurement (e.g., counting the number of low-level, more impulsive, or reactive scores). We later propose such a system.

Sensitivity to error. As mentioned by Holt, surveys with score counts near the cutoff levels are particularly sensitive to error introduced by random or uncontrolled factors, including scorer variability. For example, if the cutoff for some level is 10 items and a survey has 9, 10, or 11 items at that level, then a small difference in item scores such as due to scorer error or to a person not expressing themselves "at their best" in the moment of completing the stem would have resulted in bumping the total score to a higher or lower developmental level. Each developmental level has a significantly different description than its neighbors, so this small difference can create a large change in outcome. (O'Fallon often scores to an extra level of detail to ameliorate this issue by specifying early, mid, or late within the stage, but most trained scorers do not perform this.)

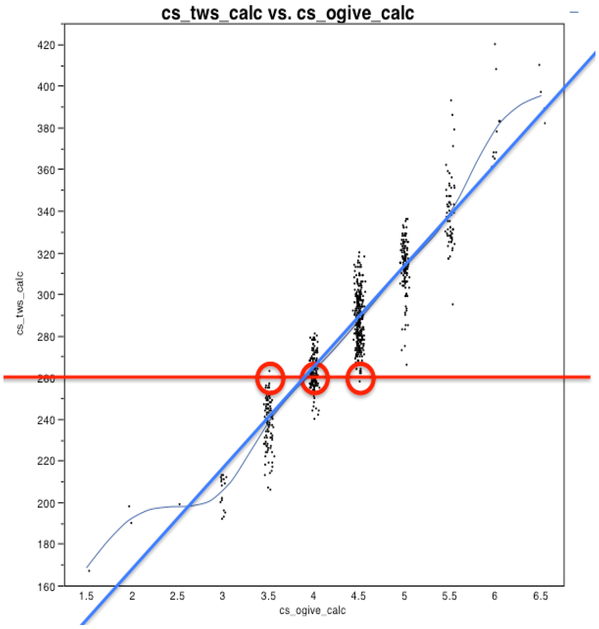

Figure 1. Ogive vs TWS.

TWS/ogive misalignment. The cutoff method produces unsystematic alignment with the TWS (or any linear item aggregation), making them difficult to compare. See Figure 1, which plots TWS vs ogive values for each survey in the STAGES database (described in the Methods section; the TWS vs ogive graphs for all of the SCT variations will have similar properties). For example, at TWS=260 (red horizontal line) there are three possible ogive values, and for an ogive value of 3.5 the TWS scores range from approximately 210 to 265. Since the TWS is a straightforward linear sum (see above footnote) of the scores, it corresponds to a more traditional and scientifically understood measurement. Scoring manuals include rough advice on how to compare TWS and ogive scores. Loevinger (1998, p. 26) includes a table with TWS ranges such as E4 conformist > TWS 146-162; E5 Self-aware > TWS 163-180; E6 Conscientious > TWS 181-200. It is problematic that the ogive has such a complicated mathematical relationship with the more basic, intuitive, and standard summation statistic used in most psychometric research, and this peculiar behavior is a direct result of using arbitrary cutoffs at each level.

Additional issues with the TWS multipliers. The progression of weights used for the standard SCT TWS calculation is somewhat arbitrary as well. In the MAP system, the lowest frequency is multiplied by 2 and the next by 3, etc., with the multiplier increasing by one per level (see Appendix 1), which makes the TWS very nearly like a summation but not exactly the summation of the items.[11] The integer progression of multipliers assumes an equal separation between each level. However, because Loevinger and Cook-Greuter occasionally modified the stage number and boundaries of their models based on data-driven and pragmatic factors, essentially changing the "joints" in how the spectrum was "cut," this assumption cannot be made.

Nothing in the theory or data analysis could address the issue of equal spacing between the levels, and thus the TWS multipliers remained arbitrary and kept shifting. With the insertion or collapsing of a level, the TWS multipliers are re-set. For example, they might still increment as in 2,3,4..., but these multipliers could correspond with different levels in any revised system, which made revised TWS values incompatible with prior results. We replace the ogive cutoff with a system that uses sums/averages in a way that does not have arbitrary multipliers and will not have to be modified as the model/theory evolves. We also show the analysis of equal spacing in the STAGES levels.

Errors in the ogive formula and assumptions. Several of our statisticians (Dolan, Johnson, Polister, and Blazej-Neradiek) have pointed to fundamental flaws in the reasoning behind the equations cited by Loevinger and Cook-Greuter and the Bayesian reasoning used. It seems that of the hundreds of studies building on Loevinger's work, none checked these basic assumptions. We believe that the flaws in these assumptions indicate only small mathematical errors on average and do not imply the need for significant revisions in past studies, however when desiring a strong foundation for the SCT, these errors represent another reason to transition beyond the ogive cutoff method. The most affected conclusions of past studies are probably those that make inferences to the general population. These types of inferences represent a very small percentage of the results of published studies, which are usually seeking correlations between ego development and other phenomena (conclusions which remain largely valid in light of the errors we will mention) rather than making claims about whole populations.

First, the formulas used by Loevinger seem to assume independence among the stems, which is not the case. Second, although the ogive method is inspired by Bayes' theorem, it also seems to violate certain principles in Bayes' theory. In the ogive procedure (Appendix 1), if a cutoff values is satisfied (e.g., 4 items are at or above 4.5/Strategist) then all other information is disregarded (i.e., the other 32 stems). Central to Bayesian theory however is the idea that each new piece of information accumulates to inform the estimate of the resultant probability, meaning information is not discarded. Third, one of our consultants noted that the method "makes sense only if the number of people above and below a level are more or less equal, which is not usually the case."

---

[11] For a simple summation, the multiplier of each level would be the order of that level, i.e. the frequency (number of) the first level would be multiplied by 1; the frequency of the second by 2, etc.; again, under the (problematic) assumption of equal level spacing.

Finally, the equation used to calculate probabilities for any level is (from Cook-Greuter, 1999; and Loevinger & Wessler, 1970):

$$Ps = \frac{Pr * {T_p}^x}{Pr * {T_p}^x + (1 - Pr) * {F_p}^x}$$

Where: P_s = probability that a person is "at" some stage s; x = number of positive signs for stage s; Pr = the assumed proportion of the population at stage s (prevalence or prior probability); Tp = the assumed true positive rate of a single sign to correctly classify at stage s (sensitivity); and Fp = the assumed false positive rate of a single sign to incorrectly classify not at stage s (1 - specificity).

Consultants Polister and Blazej-Neradiek produced a report illustrating in detail that the ogive formulation: (1) tries to assume that the survey items are independent, which they are not; (2) makes an error in the probability algebra, which has significant impact on outcomes; and (3) that the values for parameters Pr, Tp, and Fp are too arbitrary, subjective, and sensitive (i.e. small variations have substantial impacts).

The details of this report exceed our scope here (copies of that report are available from Murray). We present all of the above information as second-hand to report what our consultants found, as the author lacks the statistical skills to verify or reproduce these arguments from scratch. Such arguments are however not necessarily needed given that Cook-Greuter (in her 1999 dissertation) made significant efforts to critique Loevinger's strict use of Bayes' theorem to determine the cutoffs, especially for the higher levels. Although there was much hand-wringing in justifying the new set of chosen cutoffs, in the end they were arbitrary, as she says they are "arbitrary not in the sense of random or capricious, but in the sense of arbitrated, reasoned, deliberated." She provides a logical rationale for her cutoffs, but not a *compelling* or compulsory one, meaning that – i.e. another researcher might produce completely different cutoffs, using a valid but different rationale. The cutoff method was so standard an aspect of the SCT method that finding an alternative was, apparently and understandably, too radical a break with the tradition, and. So the "battles lines" of the methodology were thus drawn at *what* the cutoffs should be rather than *whether* a cutoff method should be used.

Summary. That there seemed to be significant problems with the ogive method was agreed upon by *all* of our consultants who familiarized themselves with the equations used (Dolan, Johnson, Neradilek, and Polisar).[12] In addition, another one of our consultants who took a cursory look at the ogive method, called it outright "indefensible." It is also true that no consultant could recall anything like this Bayesian-inspired cutoff method being used in test psychometrics in psychological or social science research.

Research Methods and Results

Method and Data Source

We include the method and results in the same section because we apply various statistical tools and software packages to a pre-existing dataset to answer our research questions. Some analysis was conducted using the R statistical package's popular IRT module (the lmt R library), while most used the Winsteps software (winsteps.com), which specializes in Rasch analysis (i.e., one parameter IRT) (Rasch, 1980; Andrich, 1988; Bond & Fox, 2001). The IRT and Rasch analysis are described in Appendix 3.

Our dataset originates from the software package and website that has been used for (1) subjects to take the SCT (survey) online and have their responses and demographic information stored and (2) for certified scorers to read a subject's responses to SCT stems and rate stems and the entire survey based on procedures outlines in the STAGES scoring manual. The data were collected and are owned by STAGES International (which was originally run by O'Fallon's prior organization Pacific Integral). We used data from the "general protocol" containing the standard 36 stems for the STAGES SCT. The data were anonymized to contain no identifying information and were stripped of the sentence completion text, with the result that the only relevant data for each survey item are the item score (1.0 to 6.5) and survey-level numerical data such as the TPR.

The data consist of 740 surveys taken by 644 clients (some took the test more than once) between March 2009 to July 2018 (i.e., over about 9.5 years). 330 clients were female, 272 male, and 42 of unknown gender. Education levels varied widely, but the vast majority were professionals with college degrees. The age frequency per survey is: 16-29: 49; 30-39:149; 40-49:186; 50-59:171; and 60-77: 115 (i.e., a relatively mature subject pool). Subjects were from a variety of locations around the world (mostly from the U.S, and EU but included Ethiopia, Australia, New Zealand, Canada, Russia, Kosovo, Pakistan, and China). All the participants spoke English as their first or second language.

Descriptive and Basic Item Statistics

Histograms. Figure 2 shows histograms for the score at the item and survey (protocol) levels. (Note that this does not represent all of the data O'Fallon has from scoring, especially for the top two levels, as there are some small research projects that are not stored in this database.) Stage 4.5 surveys predominate, which indicates the types of clients and research subjects that come to STAGES International. Frequencies at the item level are high at 3.5, 4.0, and 4.5, which differs from the survey level in large part due to how the ogive method focuses on the higher scores.[13] The IRT methods used in our analysis are robust with regard to such skews in data representation, so our conclusions should be valid for all levels except 1.0, 1.5, 2.0, and 6.5, which have very low representation.

---

[12] Note that we did not set out to, or ask these consultants to prove that the ogive method was flawed. At most we summarized arguments made by other consultants, and asked them to verify or argue with those.

To test whether standard statistic methods would apply to these data, we first investigated patterns of the 36 items within the survey and specifically the standard deviation of item scores and their normality (skew and kurtosis).

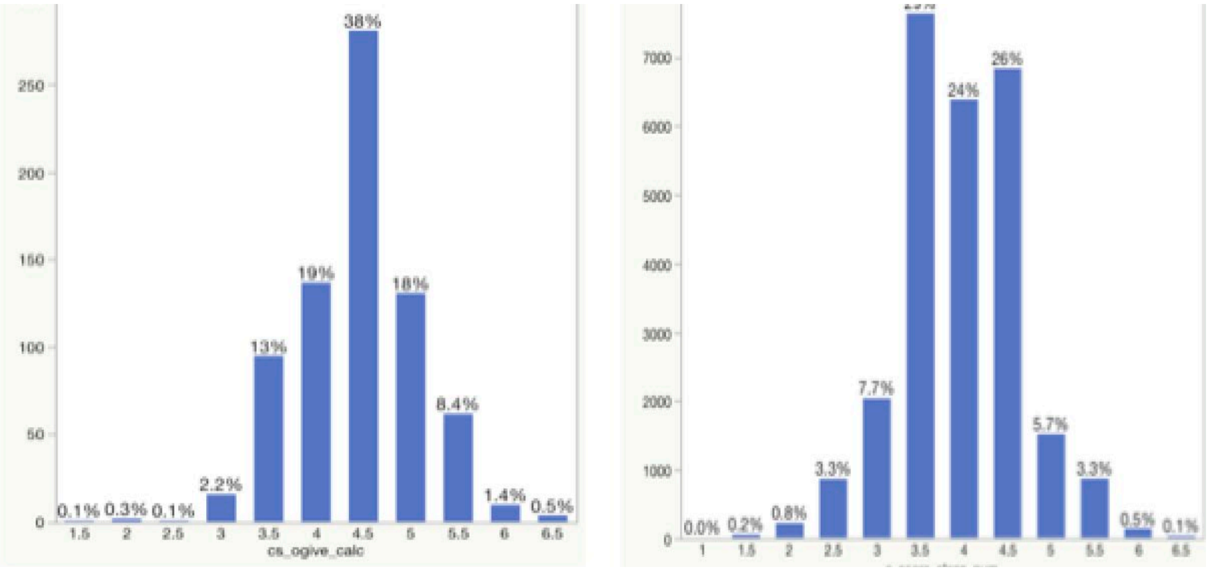

Figure 2. Histograms – Left: Survey ogive (TPR); Right: Item Scores for each level.

Table 1. Data shown in Figure 2.

Stage:	1	1.5	2	2.5	3	3.5	4	4.5	5	5.5	6	6.5	Total
#surveys	0	1	2	1	16	95	137	281	131	62	10	4	740
#items	4	57	223	870	2040	7641	6388	6839	1522	874	146	36	26640

Skew and kurtosis. We checked the skew and kurtosis measures for items within a survey, which assess how close a dataset is to a normal (bell-shaped) distribution within each survey. This answers the question of whether items on average tend to "pile up" toward the earlier or later end of the scale. Figure 3 illustrates how skew and kurtosis represent deviations from a normal distribution. Skew can be described as "lack of symmetry around the mean" and kurtosis can be described as having a long (heavy) tail. Acceptable values for both are considered to be within -2 to +2.

For our 740 surveys, the mean kurtosis was 0.37 and the mean skew was 0.18, meaning on average the scores within a survey are normally distributed around the mean. This is a bit surprising since the conventional assumption might be that, for the populations in the database, there is a longer "tail" of off-the-cuff (or shadow) answers into the lower levels. That the score distributions within surveys tend to be normally distributed, which gave us confidence that more standard aggregation methods would be applicable.

---

[13] Note the curious dip at 4.0 for item scores. We are still looking into why this might occur.

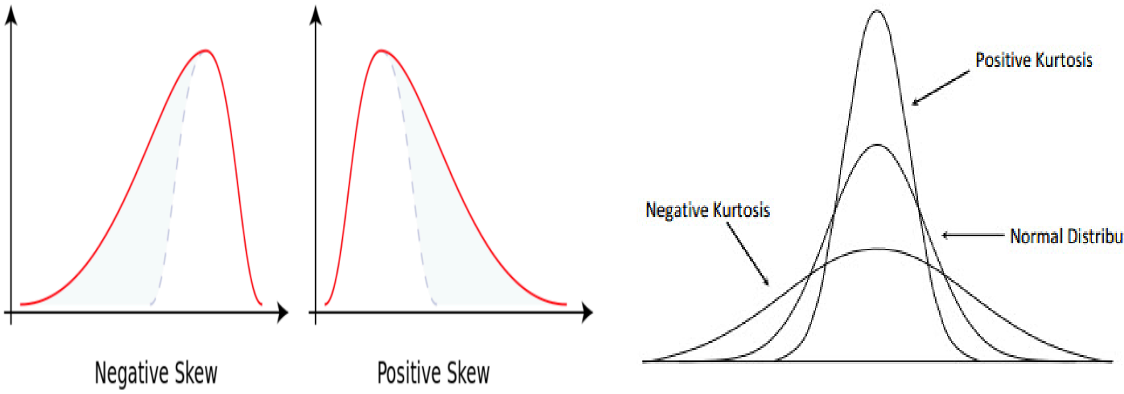

Figure 3. Illustration of skew and kurtosis deviations from a normal distribution.

Standard deviation. We also examined how the standard deviation of scores within a survey varied based on the overall survey score (ogive). The results in Figure 3 show that the standard deviations for all levels (other than the top and bottom 1.0 and 6.5) are remarkably similar (.8 to 1.2). (The error bars in the figure show the variance in the standard deviations). The overall shape of the distribution of the 36 scores within a survey thus changes little for individuals at different centers of gravity, meaning that the spread of scores or width of the item's "bell curve" within a survey is surprisingly uniform regardless of the stage. There is however a slight upward trend, which would be expected because the higher the score, the more room one has to "roam" within a projective test.

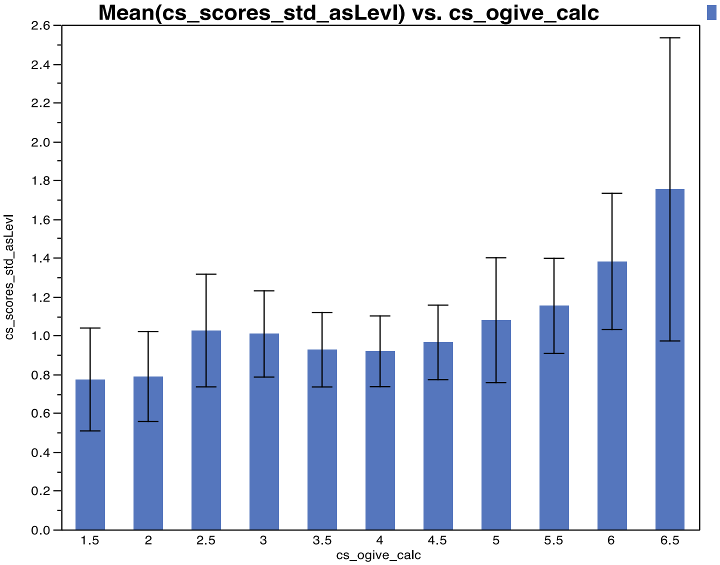

Figure 4. Standard deviation survey scores vs. stage.

These metrics also provide information about what the cutoff method is "throwing away" since it focuses on the highest scores (the number that depends on the level – see Appendix 1) and ignores the rest. As explained later, eventually we decided to calculate the total score using a standard number (6) of the highest stems. The normal distribution of the data and the fact that the SD shows the items cluster around +/- 1 or 2 levels from their mean support the reasonableness of this type of aggregation method.

Test length. Figure 5 shows a Cronbach-Mesbah curve illustrating the Cronbach's alpha score for successively fewer test stems (with the worst correlated items removed first). The curve shows that for a half-item test, the reliability is still excellent (.95) and that even with 10 stems, the SCT has very good reliability (.92) and that even at 5 stems the reliability is quite good (.85). This supports any future projects that use surveys with fewer than 36 items (which are now being deployed by Stages International). From a purely statistical perspective, one might wonder why the SCT uses so many items (assuming this pattern was also true of the WUSCT or MAP variations of the SCT, although we lack item-level data for these). According to O'Fallon, the full set of 36 responses is important for identifying themes and patterns in the detailed reports and coaching sessions given for individualized SCT assessments (personal communication).

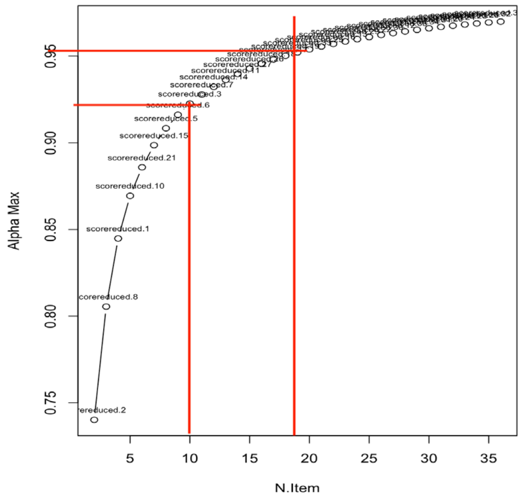

Figure 5. Cronbach-Mesbah curve.

Factor analysis. Figure 6 shows the output of a factor/component analysis of the data which, along with the numerical output, confirm the prior finding (for the WUSCT and now for STAGES) that the SCT loads on one factor and seems to be measuring one latent variable. This means that among the 36 stems, none seem to cluster together as if they were measuring a sub-skill of the overall capacity.

Item difficulties and item standard deviations. As a projective test, the SCT theoretically assumes that all items are approximately of equal "difficulty" on average. The stems are intended to "triangulate" or parallax the measurement from many life contexts (family, self, work, public life, etc.). Individuals are expected to vary regarding which life contexts evoke lower level responses (as in "shadow crashes), but the item differences are assumed to be entirely personal rather than based on item difficulty. We can use IRT to test this assumption.

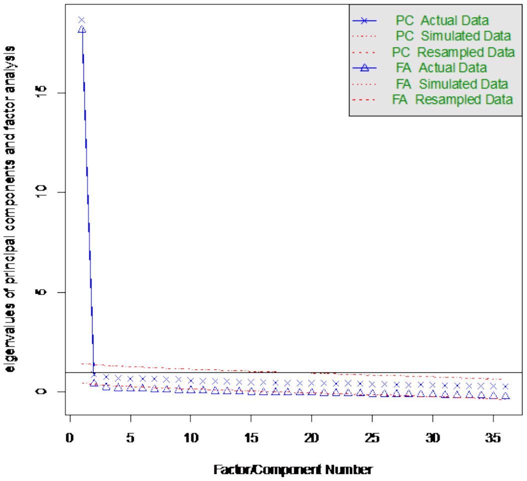

Figure 6. Factor/Component Analysis.

How different are the 36 stems? Figure 7 shows "High and Low Averages" and standard deviations per stem, and the tables are truncated to show only the highest and lowest thirds. The average score for each stem ranges from 3.71 to 4.21, which is a rather modest range indicating a small variability in stem "difficulty." Some of the stem difficulties correspond to what might be expected based on the abstraction or complexity of the stem concepts. For example, "if my mother" and "when I get nervous" elicited lower scores, and "Crime and delinquency could be halted if" and "we could make the world a better place if" elicited relatively high scores on average. The figure also shows that the stem "I am" has the highest standard deviation, which is consistent with the later IRT analysis showing it stands out as correlating the most poorly with the set of stems.

Figure 7. High and Low Averages and Standard Deviations for Stems.

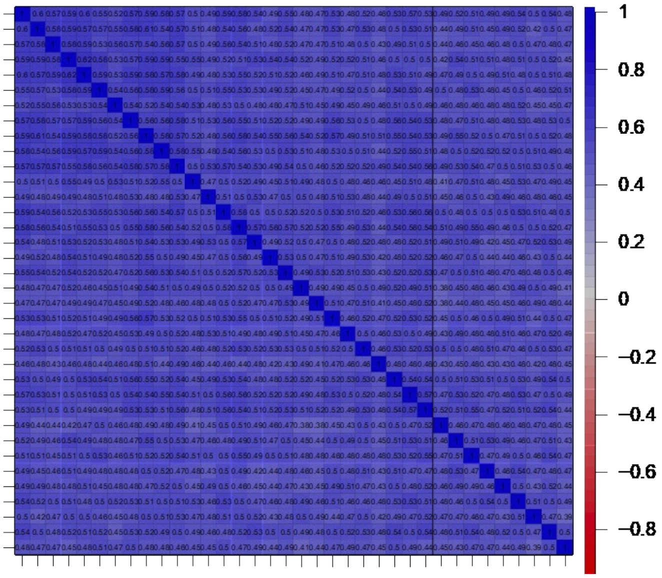

Figure 8. Item correlations Heat Map.

The "I am" Stem: The "I am" stem is the least correlated with others individually and with the overall "latent variable" (ego development) being measured, and it also stands out as the only outlier in our Rasch analysis. O'Fallon confirms that anecdotally the item has unique and interesting responses and would be the first considered for removal in a shorter test. However, we suspect that it might point to measuring an important sub-trait, which might be expanded upon with research into additional similar stems.

Item correlations. Figure 8 shows a "heat map" illustrating the correlations of the 36 items with each other, which range between 0.32 and 0.53. The Rasch analysis described later found all items except "I am" to "fit the model" of a rigorous test instrument.

IRT and Rash analysis results

We began our analysis using the R software's lmt package and then switched to the Winsteps program for more detailed Rasch analysis.[14] The two systems provide relatively equivalent answers for the tools they have in common, but each also has tools the other lacks. (Information about IRT and Rasch analysis is found in Appendix 3.)

We tested the 1-, 2-, and 3-parameter versions of IRT modeling and found that the 1-parameter version (which the Rasch model uses) was sufficient. (The 2-parameter version had a slightly higher fit, but the fit of the measurement theory with our developmental theory led us to use the Rasch modeling.) Within the IRT analysis, we tried the generalized partial credit (GPC) model and the graded response model (GRM), finding that the simpler GPC model was sufficient (both the AIC and BIC variations of the GPC model were tried with little difference found). We also conducted some preliminary experiments using models outside of the IRT framework, including "mixture models," "grade-of-membership models," and structural equation modeling (factor-analysis-based item response trees) and did not find evidence that these more complex methods added value to our analysis. Within the Rasch/Winsteps analysis for polytomous items, we used Andrich's rating-scale model" (RSM) (the simpler of two alternatives since the data fit the Rasch model well). Information on how to interpret Rasch results including WINSTEPS outputs can be found in Linacre (2018), Bond and Fox (2001), and the winsteps.com and rasch.org websites.

Overall test strength. Figure 9 shows the person and item distributions, representing the primary or most basic type of output from the WINSTEP (Rasch) analysis. The bar chart on the left shows the distribution of subjects (surveys) while the bar chart on the right shows the distribution of items (stems), both of which are in terms of the logit-scale "measure" normalized to go from -4 to +4 (technically from negative to positive infinity). What our experts can tell from this chart is that:

- The "**test coverage** is impressive" over the range
- The **distributions** are relatively normal, which is favorable. (One can see the dent in the curve representing lower occurrence at the 4.0 level mentioned in Figure 2.)
- The items are all clustered around a **similar difficulty** (the mean difficulty), as noted above. This is unusual for most tests, which are expected to have a range of easy and difficult items, but the tight range of item difficulties was expected for our projective test (see Figure 5).

---

[14] For the WINSTEPS analysis we limited the data to only those 448 surveys scores by the primary master Scorer (O'Fallon). This eliminated the possibility that results were influenced by variations in inter-rater reliability (as suggested by a consultant). Running IRT analysis with all 740 produced similar results.

Figure 9. Person and Item Distributions from WINSTEP analysis.

Other output tables from the WINSTEP analysis confirm that the test would be just as powerful with fewer items. Many items were redundant from a psychometric perspective, but for the STAGES assessment in its normal use, the full set of 36 items gives scorers, debriefers, and coaches required additional information for the client.

Item discrimination. Figure 10 shows the individual item information curves and their combination in the test information curve," which illustrates that all items on the general protocol have *good overall discrimination*. Although there is a dip for the middle values, all of the values are acceptably high. Scoring is very *consistent* (i.e., good quality) across the prompts (similar to the Cronbach's alpha results). (It would be possible to conduct a deeper analysis on how each item performs across the range of all levels, but this is not needed to answer our research questions.)

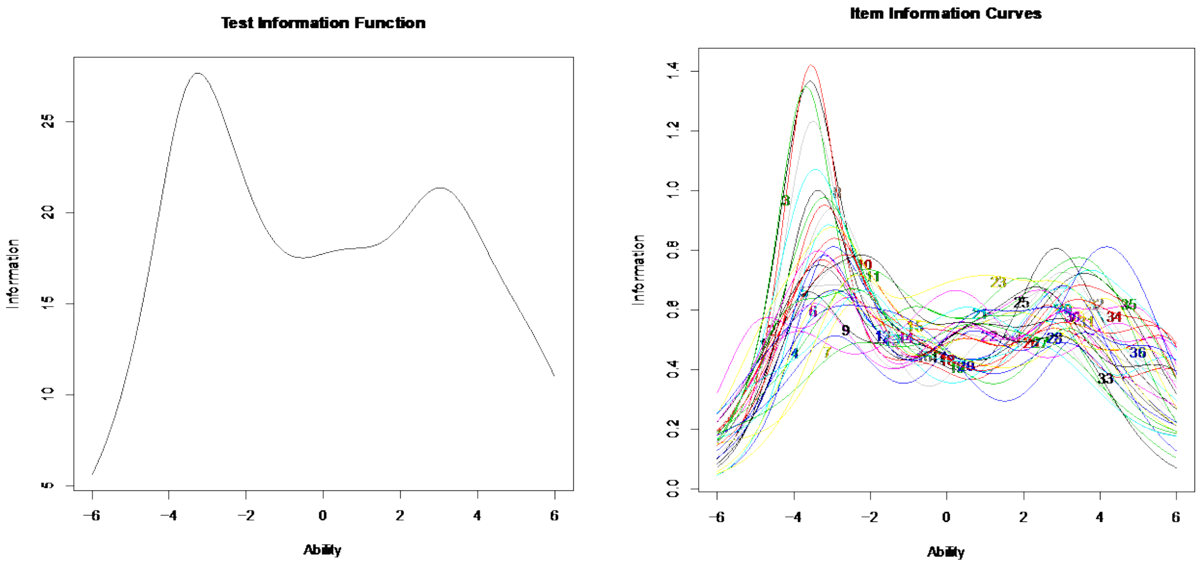

Figure 10. Test Information Curve and item information curves.

Figure 11 shows the probability category curve (PCC) which plots the probability of observing each ordered category according to the Rasch model relative to the overall item difficulty. For example, the "4.5" curve shows the probabilities of a person with an overall (average) 4.5 ability, which shows – for any given test item, what they are likely to score in terms of the latent variable (which is calibrated to 0 at the average score around level 3.8). They are most likely to exhibit about 1.5 (the peak, which is 1.5 standard deviations higher than the average), and the probability of scoring higher or lower on an item declines on both sides as shown in the figure. The first and last curves (1.0 and 6.5) are always ignored in such plots (due to the math they always extend to infinity). The intersections of the curves for adjacent categories show the "Rasch-Andrich thresholds" for demarcating the range of each category.

The curve illustrates a generally robust test, however what is notable about the graph is that every other curve is (usually) lower. The lower curves show levels (response categories) that are not as clearly differentiated from their adjacent categories, and it appears that the X.0 levels are not as crisply measured as the X.5 categories. The scoring is strong at discriminating the 6-person perspectives but not as strong at discriminating early (passive) from late (active) halves of each person perspective. This makes sense based on the hierarchical nature of the model parameters, in which the tier distinction is the most crude, the individual/collective dimension is the next most refined, and the active/passive dimension is further refined. It is also possible that the observed pattern arises because the choice of items is better at eliciting active vs. passive responses.

O'Fallon hypothesizes that these dips for the X.0 levels are also because they regard "passive" phases in which the subject is beginning to recognize objects of awareness but is still struggling to find specific language for them, so they may drop to the prior level in terms of vocabulary.

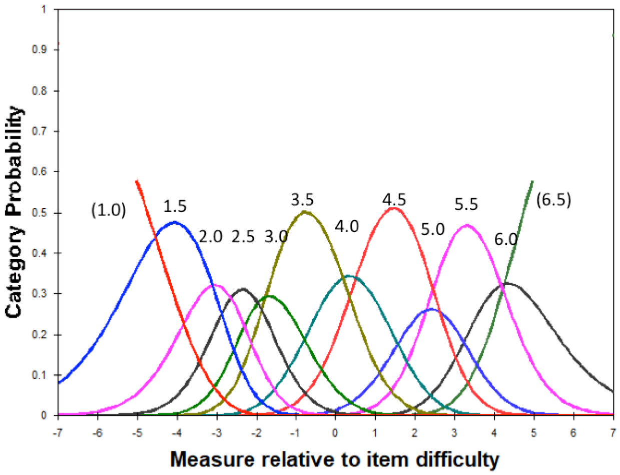

Figure 11. Probability Category Curves.

Category boundaries and step uniformity. The PCC (Figure 11) also shows that the separations between values (the curve intersections or Rasch-Andrich thresholds) is relatively even over the range, which represents a primary predication by O'Fallon.

A better method of illustrating the category boundaries regards the category demarcation graph shown in Figure 12, showing the relationship between the STAGES score for each item vs. the Rasch model measure of the latent variable. The relationship is quite linear within the normal range of scores (2.0 to 6.0 at between +4 and -4 standard deviations from the mean, which is where 99.9% of item responses fall), and the spacing between levels is relatively uniform. The relative uniformity of spacing can also be observed in the cumulative probability curves in Figure 13.

The relatively even spacing tentatively confirms O'Fallon's hypothesis that the *STAGES model cuts the developmental space into equal-spaced units.* O'Fallon proposed that one benefit of a theory-based (i.e., explanatory vs. more descriptive and data-driven) model was that it offered a consistent "ruler" against which to measure the progression of stages, which is resilient to data collected in future studies from different populations. This hypothesis is supported here.

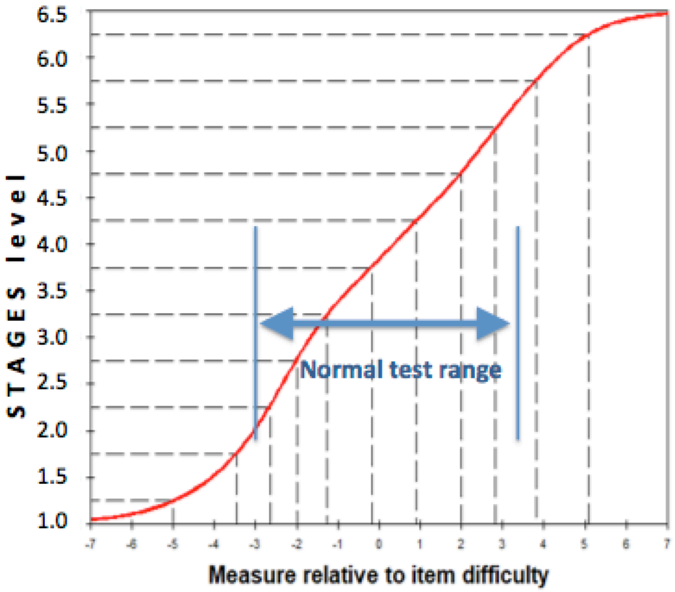

Figure 12. Stages score vs. Latent Variable Measurement.

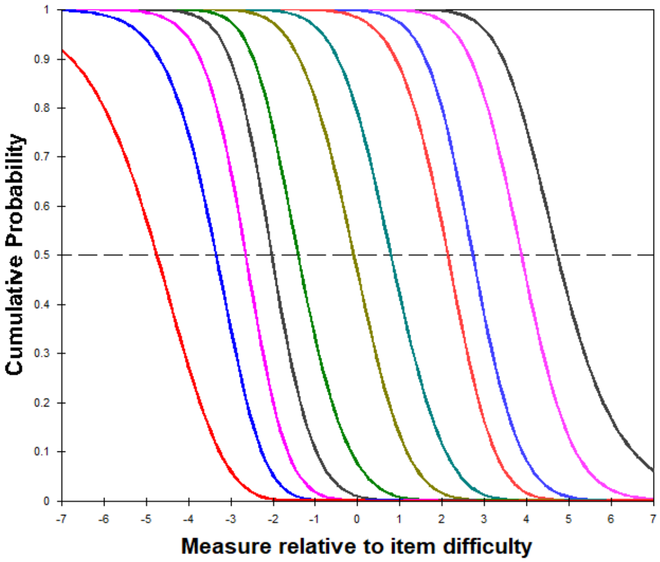

Figure 13. Cumulative probability curves.

Summary/fit table and discrimination strata. Figure 14 shows the summary table with fit statistics from the WINSTEP output. INFIT and OUTFIT statistics assess outliers and flag possible problems. The fit statistics identifying mis-fitting (infit and outfit) items is .99, which is in the "very good" range (i.e., very low misfit means – values less than 2 are considered acceptable). The reliability of the items is **excellent** at .95 and is analogous to the excellent Cronbach's alpha metric previously noted for the test.

The separation index of persons at 5.52 is noteworthy. Through a transformation formula, this provides an indication of the number of "strata" or levels that the test resolves. (This is estimated as the adjusted or "true" item standard deviation divided by the average measurement error, expressed in standard error units.) The formula for converting the person separation index to the number of discernable strata is (4S-1)/3 meaning that (4*5.52-1)/3 = 7.0 strata. This is analogous to the estimate above with the PPC curve that the test cleanly differentiates the 6 person perspectives (7 levels according to this calculation) and has more difficulty resolving all 12 levels as clearly.

The strong differentiation of 6 (or 7) levels holds for our particular dataset, which has some levels which are more highly represented. Another metric given by WINSTEPS indicates the "maximum" strata number, which "reports how many statistically different ability levels could be distinguished in a *uniform* sample covering the full raw-score range of the test." This is independent of sample size and is unlikely to be obtained for any sample (which tends to have a normal-shaped distribution). It is however pertinent to note that the "maximum strata" for our system is calculated at 24 levels (23.9), indicating that theoretically the system can differentiate at the level of the half-stage (suggesting that the strata index would improve with more data across the less well represented levels).

Figure 14. Winsteps Summary Table.

Rasch/IRT analysis summary. Whether examining Winsteps (Rasch) or R (IRT) outputs, our consultants were unanimous that the *STAGES inventory and scale is psychometrically sound across its entire range (*with more certainty about this for the levels inside the extreme ratings). Its strength had been verified in the past by repeatedly high Cronbach's alpha measurements of internal consistency ("reliability"), but the IRT and Rasch analysis contribute additional depth to this finding.

The test would be strong psychometrically at 18 or even 10 items. All items on the general protocol are strong, but the stem “I am” stands out as fitting less with the model compared to the others. The 12 stages defined by the model are relatively evenly spaced along the spectrum, supporting O'Fallon's conjecture that the STAGES model cuts the range into equal slices.

The test easily differentiates the 6 person perspectives and has more difficulty differentiating between levels at the granularity of 12 levels. We will investigate how the scoring manual or procedure might provide a more refined differentiation between the first and second halves (the actively and passively oriented) of each person perspective. According to O'Fallon (personal communication), this makes sense within the theoretical model. At the X.0 or passively oriented levels, the meaning-making system of the prior X.5 (actively oriented) level is being deconstructed and a new worldview is emerging. This process might arise in language with more variation and less precision in textual measurement.

A New Aggregation Method – The Core Stage

We have outlined many problems with the ogive cutoff method of aggregating item scores to produce the TPR. IRT (and Rasch) analysis ignores the ogive formula and assumes that the latent variable is a simple or weighted combination of the item scores, which is performed for most psychometric assessments. This is analogous (though not exactly the same as) the less-used TWS score for a survey.

Regarding the IRT and Rasch analysis, our consultants agreed that (1) the test is valid and strong examined at the item level and (2) the ogive cutoff system was problematic. We still want our developmental scoring to be compatible with the expectation that, for a projective test, a person's true "center of gravity" will be evidenced from the higher scores, and that how the lower scores are spread out does not affect this summary measurement. To achieve this, we must discard some assumptions made in IRT, as none of our consultants were able to identify any psychometric evaluations of aggregation methods for projective tests (or tests that focused on only the top items). Thus, in this respect the SCT remains somewhat an anomaly within the field of psychometrics, which is why Loevinger had to develop an alternative method (the ogive method).

We had two primary goals for designing a new aggregate method, which we ended up calling the "Core Stage."[15] First, we wanted to avoid the problems of the ogive cutoff method and use something more straightforward and with fewer arbitrary parameters. Second, we wanted to minimize the differences between the new and old scores so that we would not have to alter the established interpretation of each level (i.e., to remain consistent with how a "3.5/Achiever" total score is understood in the field). Once a method was determined, we wanted to scale it to appear as close to the prior ogive method as possible (based on the RMS error of the Core Stage vs. the ogive score).

We considered two methods: The first regarded taking the average of the top X scores, where X was to be experimentally determined. The second method was a true weighted score, in which scores of higher levels received additional weights. Our method of assigning weights was to raise scores to a power P that systematically increased with higher scores, where the power was to be experimentally determined. By "experimentally," we mean iterating over different values to identify which come closest to the old ogive score. We had confidence that these methods would not have unusual statistical properties, because (1) the IRT analysis showed the test was strong and (2) the analysis of skew, kurtosis, and standard deviation across appeared favorable for surveys at all levels.

The new aggregation methods we tried were:

- Average of the top 5, top 8, top 10, top 12, and top 18 scores; and
- Sum of the scores raised to the power of 1, 5, 8, 10, 12, 15. (Remember that scores are within 1.0, 1.5, ...6.5.)

The results are shown in Table 2. We compare each new method with the old ogive score by taking the root mean square error over the entire database (n=740). "Ave of all" is comparable with the TWS method (which regards the sum of the scores) and shows a baseline RMSE of 0.55. Note that because the scores increase by 0.5 per level, an RMSE of 0.5 represents one full level. The lowest RMSE for the TopX method was 0.22 at Top10 and Top12. When taking the average of the sum of the score raised to powers, the power with the lowest RMSE was Score^8. It appeared that this method did not produce errors as low as the TopX method and was also more difficult to conceptually resolve with our understanding of developmental progress. (We also tried combining the two methods, which did not yield a lower RMSE.)

---

[15] This term may be revised when a better one is found.

Table 2. RMS Error of alternative aggregate methods.

Method	**RMSE**
ave of all (like TWS)	0.55
aveTop5	0.30
aveTop8	0.23
aveTop10	0.22*
aveTop12	0.22
aveTop15	0.23
aveTop18	0.25
Score^1	0.48
Score^5	0.32
Score^8	0.26*
Score^10	0.27
Score^12	0.28
Score^15	0.33
aveTop10Score^2	0.24

The RMS error represents an average error over all surveys, however we wanted to more closely examine how the methods performed at each level. It is more important that the methods work well where there are the most scores, *and* having low RMSE for higher scores was more important than for lower scores (Concrete tier), because we realized that our new method was re-conceptualizing the interpretation of low-level scores. The ogive score conflates shadow crashes with meaning making complexity, and we wanted the new measure to focus on meaning making complexity (or maturity).

Figure 15 shows histograms displaying the scores of the new methods (Y axis) vs. the old ogive score (x axis). The bar marked "SAME" provides comparison to illustrate the "straight line" one would achieve if a new method gave the exact same score as the ogive method. Although "top 10" provided the best results, we decided to use either Top6 or Top12, which had RMSE's practically as good since they represent exactly 1/6th or 1/3rd of the 36 stems. Top6 always performs better than Top12, and both always perform better than the average, so we choose the method of (average of the) Top6 (or top 6th for surveys with other than 36 items) for the new Core Stage.

Next, to bring the Core Stages even closer to the old ogive scores, we performed a linear transformation of the Top6 score. Linear fitting showed that a formula of (1.2*AveOfTop6)-1 would yield a score even closer to the old ogive. We call this the "adjusted" Top6, which is also shown in Figure 14. The adjusted top6 performs better for most of the subtle and metaware levels, and it is unimportant that it does not perform as well for the Concrete tier.

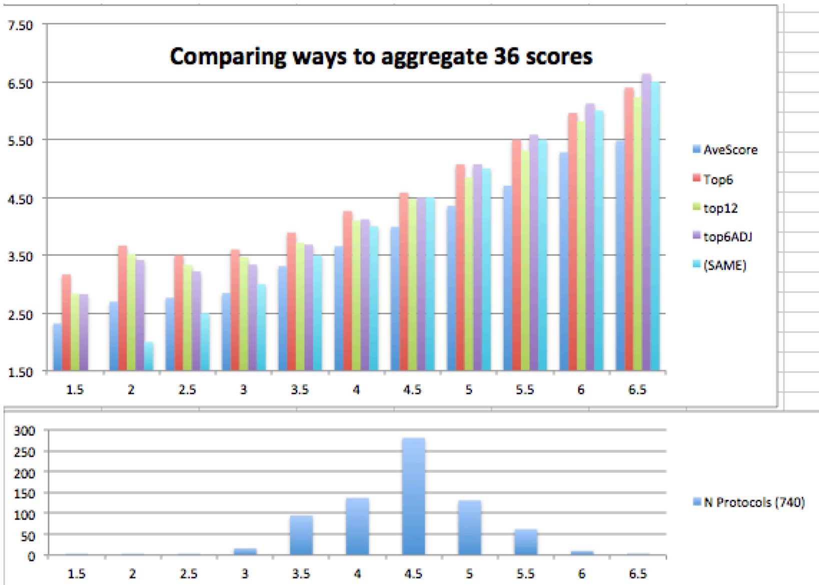

Figure 15. Comparing aggregation methods across all levels.

Core Stage. In summary, the new aggregate method called the Core Stage uses the formula *(1.2 * AveOf-top6)-1.* For protocols of arbitrary length, the Core Stage takes the top 1/6th of the scores.[16] Unlike the ogive score which yields a category, the new Core Stage value yields a continuous number (which is usually rounded to one decimal digit). The benefits of the Core Stage method vs. the ogive include:

- It yields results that are usually close to the old ogive score (but only on average).
- It is easy to calculate (uses a formula rather than a procedure).
- It behaves more predictably like standard average or total scores used in psychometric analyses.
- It does not confuse shadow with complexity maturity and can thus be useful for scoring children (which O'Fallon has begun doing).
- It is not based on a suspicious or erroneous application of Bayes' theorem.
- It does not force scores into categories but allows fractional values.
- It is not sensitive to small differences in how stems are scored (which occurs in the ogive method near the cutoffs).
- The new Core Stage rating makes it easier to produce a total score for protocols of any length (one does not have to worry about inventing new cutoffs).
- It does not contain a large number of arbitrary parameters (such as the 12 ogive cutoffs and 12 TWS multipliers and the other Bayesian parameters). The primary ad-hoc

---

[16] When N is not divisible by 6: Where 36/N = I(nteger).R(emainder) (e.g 2.667), Ave_top_6th is the weighted mean where the top I are given weight 1, and the I+1th score is given a weight of R, the rest given weight 0.

> parameter is the "6" (or 1/6th) by taking the top 6 scores. Our analysis indicates that outcomes are not overly sensitive to this parameter (i.e., 5 to 10 behaves similarly), however tuning this parameter remains an open question. In addition, the specific formula for aligning the Core Stage with prior ogive values is dependent on the dataset used and may need to be adjusted in the future.

This Core Stage measure has been added to the STAGES assessment software (on both the "Training Platform" and the "Production Platform"). Both the new Core Stage (and additional metrics discussed below) and the prior ogive and TWS metrics are currently shown. We are in a period of training scorers to use and understand the new method, however the old method will be used for at least another year for reporting results to clients.

For several months, O'Fallon has been observing that the Core Stages closely match her intuitions about developmental stages, are close to the old ogive score, and function even better than the old ogive score in the Concrete tier.

Additional measurements: Average, Bottom, Spread. The new scoring system shows several measures in addition to the Core Stage: The *Average* (across all stems); *Bottom Score* (the average of the bottom 6, related to a "shadow score" for adults); and *Spread* – the spread score is the Core Stage minus the Bottom Score, and indicates the range of values in the survey.

Early and Late stages. Prior to this work and continuing after it, advanced scorers use an additional set of text analysis instructions to determine a sub-level rating of early, middle, or late within each level (for each stem). Although this refinement of the item score is not included in the ogive (or TWS) calculation, it can be considered when the total survey score is tweaked based on global considerations.

The new Core Stage allows for fractional values, which provides another indication of early/middle/late sub-levels within a stage. We still need to further consider how these two methods of sub-stage scoring (i.e., Core Stage fractional level vs. text analysis rules for sub-level) will coordinate with each other. These two methods will not necessarily coincide, and it remains to be determined how they will be resolved.

In addition, the question arises RE where along the fractional scale we call "early" and "late." For example, *early* 3rd-person perspective could be just *below* "3.0" as in "2.9 or 3.0" or it could be just at and above 3.0 as in "3.0 and 3.1." We have decided tentatively to use the convention shown in Table 3 and illustrated in Figure 16.

Table 3. Decimal fractions vs. early and late for stage X.

X.0 early	X.5 early
X.1 mid	X.6 mid
X.2 mid	X.7 mid
X.3 late	X.8 late
X.4 transition between	X.9 transition between

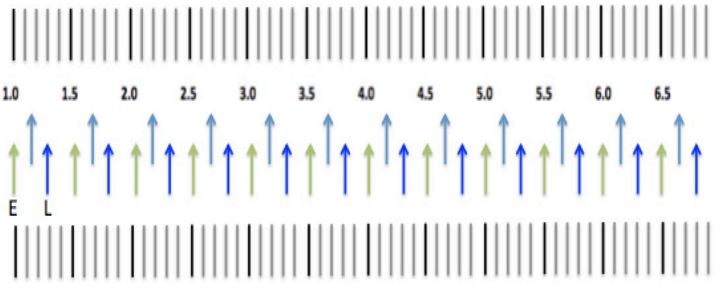

Figure 16. Early and Late stages, illustrated (Early in green, late in dark blue, middle in light blue).

As indicated, the fractional Core Scores will be rounded to the nearest single decimal value. In reports that classify scores at the granularity of each developmental level, as if "rounding" to a developmental level, we will round the X.4 and X.9 fractions up and the other fractions down. For example. 2.9, 3.0, 3.1, 3.2, 3.3 will be rounded to "3.0" and 3.4, 3.5, 3.6, 3.7, 3.8 will be rounded to "3.5."

Although this has not yet attempted, it would be possible to adjust the item scores based on the sub-level text analysis of the stem completions. The Core Stage could be adjusted in the following manner if early or late indicators were found:

- for early, add 0
- for unspecified or middle, add 0.15
- for late, add 0.35

This corresponds with the method shown in Table 3 and Figure 16.

Conclusions and Future Work

This research has increased our confidence in the STAGES theory, model, and scoring methodology and has contributed some discoveries that arguably, could apply to other SCT frameworks as well. The SCT method of measuring ego development generally stood up well under the lens of IRT and Rasch analysis.

We have also produced a new method for calculating the aggregate (total) score over the 36 stems (or fewer), which we call the Core Stage. The Core Stage has many desirable properties, as noted in the prior section. The STAGES framework will be gradually shifting over to this new method, however we remain agnostic regarding whether other SCT frameworks should adopt this method (or any alternative to the ogive method). The ogive method has been performing well enough over the years, represents the default standard, and the effort to adopt a new method may well outweigh any benefits. The benefits of changing are greater for the STAGES model vs. other SCT variations, because others use a fixed set of stems (sometimes splitting the survey in half), while the STAGES allows for creating valid surveys with new stems of any length, which would require ongoing alteration of cutoff values, which can only be performed in arbitrary ways. In addition, automated computer scoring exists for the STAGES model (see www.stagelens.com), which means the SCT will become more practical to use for large-scale research where the validity of methods is critical.[17] (The companies using the MAP, LGP, and

---

[17] This automated scoring is not as accurate as human scoring, but is accurate enough for statistically valid studies of groups of 20 or more.

GLP are exclusively focusing their assessment work on individual assessments and the quality of their coaching and consultation with individuals and teams, as far as we know.)

Study limitations. Limitations of our research methodology and results include the fact that the sample population is on average higher than the general population. Although IRT analysis is expected to be fairly resistant to such skew effects, the results may be more robust if we obtain more scores from the 2.5, 3.0, and 3.5 levels, which we will attempt to do. The analysis was limited to the STAGES general protocol and to data collected before mid-2018. A larger dataset is now available and might be used to update some results.

Although the Core Stage method does not contain a large number of arbitrary parameters (such as the 12 ogive cutoffs, the 12 TWS multipliers, and the other Bayesian parameters), it does contain some arbitrary parameters, specifically the "6" (or 1/6th) when taking the top 6 scores. Our analysis indicates that outcomes are not overly sensitive to this parameter, and the specific formula for aligning the Core Stage with prior ogive values is dependent on the dataset used and may need to be adjusted in the future.

Future research. Future research could further explore:

- Given the predominance of 4.5 surveys, it would be useful to acquire more data in the database for lower stages.

- RE the "strata" metric and weaker ability to differentiate all 12 levels, it might be possible to modify the coding manual to better differentiate early from late stages (and active vs passive), one method for which would be to compare surveys with Core Stages around "X.5" with those at X.0 above and below them and seek additional principles that would differentiate the X.5's.

- We could more closely examine the differences between stem items regarding their average difficulty and standard deviations and which levels they better perform at differentiating.

- We could more closely examine what occurs with the "I am" stems and determine whether additional stems could be invented that target the same sub-capacity.

- We could investigate the dip in the number of stems scored at 4.0 over all items.

Appendices

Appendix 1: TWS calculation and ogive cutoffs

The original STAGES TWS formula is an extension of that used by Cook-Greuter and Loevinger and multiplies the frequencies of each level by a factor and sums those results using these factors:

Level	1	1.5	2	2.5	3	3.5	4	4.5	5	5.5	6	6.5
Factor	2	3	4	5	6	7	8	9	10	11	12	13

Table 4 below is used to determine the final derived score. The STAGES model uses the identical approach utilized by Loevinger (1998) and updated by Cook-Greuter (1999) but adds three levels (2.0, 5.5, and 6.5).

Loevinger and Cook-Greuter use a "cutoff" method they called the "ogive" method to aggregate the scores of the 36 completions to produce an overall "center of gravity" score for each inventory. The cutoff method regards a procedure where each step says "if there are X or more completions at level L then the final score is L," where X differs depending on the level. Below is a summary of the cutoff approach used for the STAGES model.

Note how the levels tested begin with the highest (6.5), move down to 3.0, and then begin at the lowest and work up to 2.5. This is because the cutoff numbers were determined by CG/L using a method that they linked to Bayes' theorem. The 2.5 (Diplomat) level was estimated by Loevinger (and Cook-Greuter) to be the most prominent in the normal population and thus the most likely given no additional evidence. This is why 2.5 represents the final or "default" value in the procedure.[18]

Cook-Greuter used the cutoff of 4 for the 2 levels above Strategist (4.5), and STAGES duplicated that approach by using 4 for all stages above 4.5.

---

[18] This Ogive method contains a number of assumptions and approximations which we will discuss in a future paper. What is important here is that the method is the de-facto standard that has been used in the numerous research studies using ego development assessment for almost 40 years.

Table 4. Cutoff Rules For a 36–Item Sentence Completion Test.*

(Do steps in order and stop where true) **If there are:**			**Assigned stage**
4	or more rated at	6.5 or higher	6.5
4	or more rated at	6.0 or higher	6.0
4	or more rated at	5.5 or higher	5.5
4	or more rated at	5.0 or higher	5.0
6	or more rated at	4.5 or higher	4.5
9	or more rated at	4.0 or higher	4.0
14	or more rated at	3.5 or higher	3.5
17	or more rated at	3.0 or higher	3.0
7	or more rated at	1.0	1.0
7	or more rated at	1.5 or lower	1.5
7	or more rated at	2.0 or lower	2.0
-	If none of the above, use		2.5

** Starting at the highest stage 6.5 and proceeding down the table, assign the stage from the first row where the rule applies.*

The cut-point criterion in the higher stages 5.0, 5.5, 6.0, 6.5 is analogous to the cut points in the Cook-Greuter scale.

Figure 18. STAGES Tiers & Repeating Principles
Asterisks (*) show levels added in STAGES vs MAP model.

O'Fallon has speculated a fourth tier in the STAGES model, continuing the repeating patterns observed in the first three tiers into 7.0, 7.5, 8.0, and 8.5. This fourth tier is based on her reading of Aurobindo's description of these rare stages of development.

Below is a table showing correspondences between five developmental models gleaned from sources in the literature. Definitions of levels of different models do not usually exactly align but share sufficient characteristics that they are comparable.

Table 5. Correspondences of Levels in Five Developmental Models.

O'Fallon	Loevinger	Cook-Greuter	Torbert	Kegan
6.5 (Illumined)				
6.0 (Universal)		Unitive	Ironist	
5.5 (Transpersonal)				
5.0 (Construct Aware)	Integrated e9	Construct-aware / Ego-aware	Alchemist/ Magician	
4.5 (Strategist)	Autonomous e8 (i5)	Autonomous, Self-actualizing	Strategist	Self-transforming/ Inter-individual (5th)
4.0 (Individualist)	Individualistic e7 (i4/5)	Individualist, Self-Questioning	Individualist

3.0 (Expert/Specialist)	Self-aware e5 (i3/4)	Self-conscious, Skill-Centric	Expert/ Technician	
2.5 (Diplomat/Conformist)	Conformist e4 (i3)	Conformist, Group-Centric	Diplomat	Socialized/ Interpersonal (3rd)
2.0 (Rule oriented)	(Delta/3)			
1.5 (Opportunist /Egocentric)	Self-protective e3 (i 2/3, opportunist, delta)	Self-defensive, Self-Centric	Opportunist	Instrumental/ Imperial (2nd)
1.0 (Impulsive)	Impulsive e2 (i2)	Impulsive	Impulsive	Impulsive (1st Order)
	Pre-social e1 (i1)			

Most scholars agree that there is substantial overlap and that the various theories are more or less discussing the same thing. There are however differences as well, and these become important as one tries to compare one theory to another or assessments made within one model to assessments made within another. Although there are differences, the similarities and alignments are actually quite striking since many were independently developed, which supports the overall validity of the developmental approach.

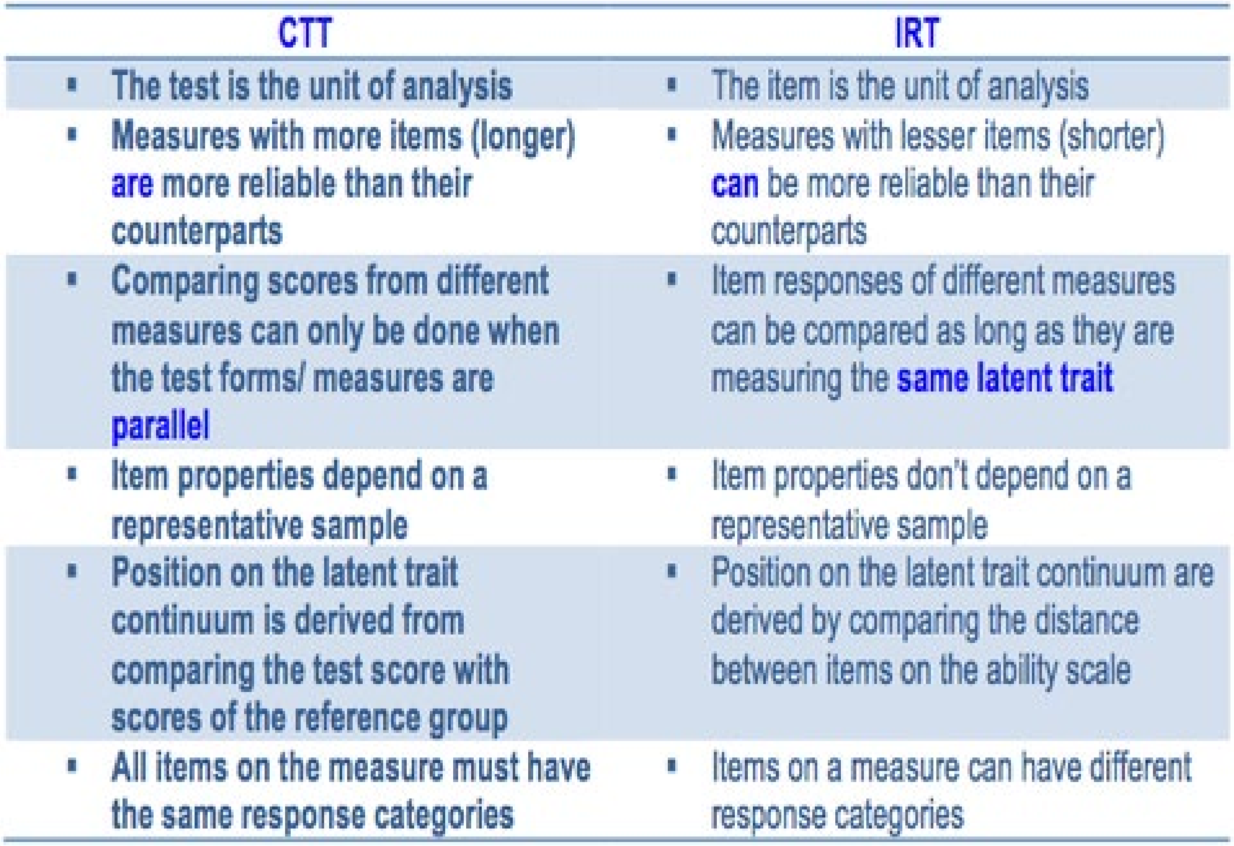
Appendix 3: Item response theory and Rasch analysis

IRT (also known as latent trait theory, strong true score theory, or modern cognitive test theory) represents a main school/toolbox in modern psychometrics (it is the method used in validating high-stakes tests such as the SAT and GRE). It specifies statistical methods for use in assessments that include many items to assess a single human trait (called the "latent variable" since it cannot be directly measured). Rasch analysis is usually considered a subset of IRT that, for theoretical reasons, is limited to "one-parameter" modeling (IRT includes a family of 1-, 2-, and 3-parameter models).

Whereas they are well-known in psychometric circles, Rasch’s (1980) models for measurement have been employed by developmental psychologists only recently (Andrich & Constable, 1984; Bond, 1994; Dawson, 1998, 2000; Müller, Sokol, & Overton, 1999).

Although IRT does not address the question of how to aggregate item scores for a projective test, we performed an IRT analysis of the STAGES database of scored protocols to establish a firm foundation for whichever aggregation method we chose to replace the ogive cutoff method.

Item Response Theory. The table below illustrates key differences between classical test theory and IRT (including Rasch analysis). (The Wikipedia entry on IRT also provides a useful overview.)



CTT	IRT
▪ The test is the unit of analysis	▪ The item is the unit of analysis
▪ Measures with more items (longer) **are** more reliable than their counterparts	▪ Measures with lesser items (shorter) **can** be more reliable than their counterparts
▪ Comparing scores from different measures can only be done when the test forms/ measures are **parallel**	▪ Item responses of different measures can be compared as long as they are measuring the **same latent trait**
▪ Item properties depend on a representative sample	▪ Item properties don't depend on a representative sample
▪ Position on the latent trait continuum is derived from comparing the test score with scores of the reference group	▪ Position on the latent trait continuum are derived by comparing the distance between items on the ability scale
▪ All items on the measure must have the same response categories	▪ Items on a measure can have different response categories

Figure 19. Classical Test Theory vs. Item Response Theory.

Item response theory creates a single scale used to measure the latent variable (i.e., the human skill or "proficiency") *and* the difficulty of an item (and the score for the whole test), which allows item difficulties and person abilities to be meaningfully compared. For example, a value of "3.2" means the same thing regarding the latent variable when used discuss the skill level of an individual, the difficulty level of an item, or the overall score on a test. Item response theory can calculate the difficulty and information power of each test item at each trait level.[19] For example, an item or an entire test can be found to reliably differentiate weak from moderate ability but can be poor in differentiating between moderate and advanced abilities.

One thing that distinguishes IRT from "classical" test theories is that it does not assume that each item is equally difficult, meaning it calculates an item difficulty for each item. Item response theory assumes that the probability of a correct response to an item is a mathematical function of person's skill and the parameters (primarily difficulty) of an item. Item response theory analysis begins with a sufficiently large set of test data and, using that assumption, iteratively works backwards to calculate (1) the difficulties of each item and (2) the overall skill of each test-taker (this type of method was infeasible before computers, which is one reason it was less popular when Loevinger began her research).

Item response theory converts the measurement (latent) scale of test into a standardized form. By using "logistic" scaling, the scale is always normalized such that (1) the mean value is 0 (i.e., negative values are below average); (2) the range is a true scalar (continuous or interval scale) in that it is infinite in positive and negative directions (even if the test items cover a specific range as in a 1-5 Likert scale or a 0-100% correct score for a math problem); and (3) the standard deviation is 1 (i.e., the scale works conceptually like a bell curve or "Z-score" with standard deviations marked on the x axis). Item response theory models posit that the difference between an item’s difficulty and a person’s ability reflects the probability of a person succeeding at a given task (at least for the 1-parameter version).

One strength of IRT (and Rasch) analysis is that the parameters of the models are generally not sample- or test-dependent and can thus be generalized to different contexts. (Note that "polytomous" IRT methods were used here, meaning those applying to non-binary measurements.)

Item response theory analysis can be used to answer questions including: do any of the items *or* any of the test-takers seem to be *outliers* (i.e., have an unusual relationship between skill level and item response)? For more information, see the figure in Appendix 4 "IRT vs. Classical test theory."

- calculate total test scores that take into account variations in the strength (reliability or information power) of each item;
- determine the reliability of items and of the test as a whole, including the information power of items (or the test) to assess each part of the scale;

---

[19] An item’s difficulty is defined as the trait level required for participants to have a 50% probability of answering the item correctly. If an item has a difficulty of 0, then an individual with an average trait level (i.e. of 0) will have a 50/50 chance of correctly answering the item.

- find outliers or misfits in test items, indicating that they do not function as expected and should be changed or removed;

- identify outliers in the test-taking subjects, such as those who answer typically difficult items correctly but answer typically easy items incorrectly;

- estimate the similarity of the gaps between ordinal trait categories and the resolution or number of such categories that a test can differentiate;

- test for the uni-dimensionality of the construct regarding whether the test as a whole measures a single latent variable.

Rasch Analysis. Rasch analysis (Rasch, 1980; Andrich, 1988; Bond & Fox, 2001) is usually considered a subset of IRT, although many Rasch proponents maintain that its underlying philosophy of measurement theory is distinct. Item response theory includes 1-, 2-, and 3-parameter models, while Rasch proponents advocate for no more than 1 parameter. "Parameters" regard numbers that characterize each item differently, where the first and primary parameter is the item difficulty and second parameter is the item "sensitivity," which measures essentially how quickly the item responds to changes in skill level. A maximally sensitive item will have a sudden jump between level X and the next level with low and high plateaus on either side of that jump, meaning that it discriminates above and below that value (its difficulty value) extremely well but does not discriminate among the lower or higher values, and does not discriminate among the higher values. One could think of this as asking "how much *information* does an item contribute to differentiating each level from others?" The third parameter sometimes introduced regards the likelihood of "guessing" the correct answer for each item.

For reasons related to foundational theories of measurement, the Rasch community says that only the 1-parameter model produces a "true" continuous scale of the type used in measurements in the hard sciences. They constrain analysis to use the 1-parameter model and identify items (and subjects) for which the data fall outside of this model as outliers, which means that the test item should be removed or revised. In contrast, the more standard IRT method adopts a purely statistical modeling approach that uses as many parameters as needed to find a model that best fits all the data. The details of this controversy exceed our scope, but our consultants have indicated that for our dataset, the difference does not matter and that the 1-parameter analysis compatible with Rasch assumptions is sufficient.

Commons and Pekker (2009, p. 13-14) summarize the Rasch model by saying that it: "Transforms raw data into unidimensional, abstract, linear, equal-interval scales if the data fit the model. Equality of intervals is achieved through log transformations of raw data odds. The Rasch model is the only model that provides the necessary objectivity for the construction of a scale that is separable from the distribution of the attribute in the persons it measures...It works by using probabilistic equations to convert raw ratings of items into scales that have equal intervals if the data fit the model. Such a scale can then be used as a type of objective ruler against which to measure the data on items as well as on respondents (Andrich, 1988). Statistically speaking, this scale will be linear."

The STAGES Specialty Inventories: Robustness to Variations in Sentence Stems

Terri O'Fallon[1] and Tom Murray[2]

Abstract: The STAGES developmental model is a variation of prior ego development frameworks that defines developmental levels in terms of three parameters: object of awareness (concrete, subtle, or metaware), individual vs. collective focus, and active/passive orientation. STAGES, like prior frameworks, uses a sentence completion test (SCT) assessment. Prior frameworks rely on exemplar-based scoring that is closely tied into the specific sentence stems. In contrast, STAGES scoring system is based on language properties that do not depend on the sentence stem. Thus STAGES is the first such assessment to be able to freely incorporate alternative sentence stems without the labor intensive process of discovering the full range of specific responses. Though the STAGES theory and assessment methodology easily allow for using alternative sentence stems, the validity of using alternative stems needs to be shown. In this paper we report on internal consistency studies of several "specialty protocols" which are SCT surveys with 6 to 10 of the original 36 stems replaced by stems focused on a particular specially area. Results show strong reliability scores, via the Cronbach's alpha statistic, for six specialty inventories, on: leadership and organizations, love, education, psychological reflection, climate change, and a children's SCT.

Keywords: Cronbach's alpha validity, children's and adult assessments, ego development, protocol variations, STAGES.

Introduction and Background

Motivations. The STAGES developmental model is a variation of prior ego development frameworks that defines developmental levels in terms of three "parameters" (or "drivers"): object of awareness (concrete, subtle, or metaware), individual vs. collective focus, and active/passive orientation. It uses a variation of the sentence completion test (SCT) that began

with Loevinger’s Ego Development research (1998) and was updated by Cook-Greuter (1999). The prior frameworks rely on exemplar-based scoring that is closely tied into the specific sentence stems. In contrast, STAGES scoring system is based on language properties that do not depend on the sentence stem. Thus STAGES is the first such assessment to be able to freely incorporate alternative sentence stems without the labor-intensive process of discovering the full range of specific responses. Though the STAGES theory and assessment methodology easily allow for using alternative sentence stems, the psychometric validity of each use of alternative stems still needs to be shown. In this paper we report on internal consistency studies of several "specialty protocols" which are SCT surveys with 6 to 10 of the original 36 stems that are replaced by stems focused on a particular specially area. We will also summarize research on the validity of SCTs of varying length, another dimension of survey variability.

Prior Research

Validity of the SCT and the STAGES scoring system. The SCT for ego development is a robust assessment instrument. Westenberg et al. (2004) conclude that "findings of over 350 empirical studies generally support critical assumptions underlying the ego development construct" (p. 485). In Murray (2017) we give an overview of the history of research on the SCT for inter-rater reliability, internal consistency, test-retest reliability, face validity, construct validity, incremental validity, clinical utility, external validity, and predictive validity. A summary of those findings is also included in *A Summary of Research on and with the STAGES Developmental Model* in this issue. In that article, we summarize validity studies particular to the STAGES model. In this paper we are interested in two issues: the primary one being the robustness of the SCT model to variations in sentence stems, and secondarily, its robustness to reducing the number of sentence stems. Next we summarize prior research on these two questions.

Variations in SCT stems. Historically, within the lineage of ego development research (and several other developmental models), stages of human development have been identified by interviewing or observing samples of people, recording their responses and organizing these responses into categories. Researchers then sequenced these categories of responses from the earliest to the latest level of maturity. These categories could then be used to identify where a person might fall in their developmental journey through life. This is the method used by other SCT projects and is outlined in a dissertation on the construction of and validity measures of one new sentence stem “A good Boss” (Minard, 2009).

As to variations in the choice of sentence stems ("test items"), we can make several observations. Loevinger adapted the sentence items numerous times before settling on a final version. There is nothing particularly special about the stems Loevinger used. Though they were carefully chosen and vetted; many were drawn from the experience of prior researchers, and the entire set evolved over the years before settling into the current standard form of the WUSCT. Others have used alternate forms of the WUSCT tailored to men, women, or youth.

Sentence starters can be inadequate for a variety of reasons, e.g. they may be vague and thus understood in very different ways; they may coerce an overly limited developmental range of responses; or they may introduce biases of various types. Thus new stems must be pilot tested for clarity and psychometric validity. But assuming that this due-diligence work is done to ensure that questions are adequate, overall prior research *suggests* that the strong psychometric properties of the SCT are robust to changes in the choice of sentence stems. However, the general question of stem flexibility has not been addressed until this study. Rather, specific sets of stems have been tested in the past.

Ego development (meaning-making complexity) is a holistic capacity spanning all life-contexts (though we may exhibit maturity different than our "center of gravity" in any given context). The stems are meant to probe across a variety of contexts, and triangulate toward an overall measurement. Cook-Greuter (1999) notes that:

> As Fischer, Hand, & Russell (1984) pointed out people tend to respond optimally to a task in 'domains in which they are highly motivated.' To tap this motivation, the SCT stems were devised to address ordinary everyday experiences shared across a wide spectrum of people. (p. 52)

Kegan's and Wilber's framing of a holistic span of life contexts as including subjective, intersubjective, and objective (I/we/it) contexts. Loevinger (1985) describes the span of stems in a related way:

> Looking at item content, the stems can be classed as *first* person (My father –, When they talked about sex, I –), *third* person (Sometimes she wished that –, Usually he felt that sex –), and common noun or *impersonal* (A good father –, Being with other people –). (p. 424)

Some stems seem to be sensitive to particular transitions along the developmental spectrum, and this is another reason for having an adequate diversity of stems. For example, some stems are related to impulse control which comes on line at second person perspective, and increases gradually or levels off for later levels. Therefore, sentences sensitive to impulse control are also sensitive to the transition from pre-conventional to conventional levels. Abstract and formal thinking begins at third person perspective, and increases gradually or levels off after that, so we would expect that certain stems are more sensitive to transitions in this part of the spectrum. In general we would expect that, to a weak but statistically significant degree, certain sentence stems are better at signaling changes in specific levels. Murray (2020) includes item response theory analysis that shows which stems do in fact load for higher vs. lower levels (i.e. "item difficulty"). However, in general, the data indicate that all of the stems are of comparable difficulty, and that every stem elicits responses from across the developmental spectrum, as is intended by the SCT design.

Torbert & Livne-Tarandach (2009) report on variations of the WUSCT that have evolved into Cook-Greuter's MAP and Torbert's LDP and GLP instruments. Cook-Greuter and Torbert modified Loevinger's protocol to "omit a number of gender-based items and, include work and leadership-related stems" (IBID, p. 132). Torbert's LDP is also shorter (24 items) and includes six new stems not in the WSUTC. Torbert & Livne-Tarandach (IBID, p. 134) report that "the responses to the new stems correlate better with an individual’s overall profile rating than responses to the former stems did, thus improving the overall reliability of the measure."

O'Fallon made additional adjustments to stems to derive her General protocol (or "inventory"), the standard set used in her research and consulting before she began branching out into "specially protocols." As described below, modifications were to insure that that stem collection had an equal representation from the "four quadrants" of I/we/it/its as explained later.

Variations in SCT Length. As to the *length* of the SCT: Novy & Francis (1992) compared the split-half versions of the WUSCT (18 items each). They conclude "these results provide empirical justification for those users of the SCT who have the need for shorter, interchangeable, and reliable forms of the test."[3] Holt (1980, p. 909), experimenting with a 12-item short form of the WUSCT found that inter-rate reliability was "at least as good as…reported by Loevinger; and the internal consistency…was quite adequate....Analyses of other data indicate that the short forms are representative samples of the full [WUSCT]".[4] He goes on to say the data show that "an abbreviated form of Loevinger's WUSCT is a reasonably reliable, feasible, and useful instrument for large-scale research...[and is]… a representative sample of the larger instrument, which probably gives substantially the same results" (p. 916). Basic psychometric theory predicts that more evidence will result in better accuracy, so for individually-based assessments, done for coaching or consulting purposes, the full set of items is still recommended, but for research or group-statistical assessments, it would appear that shorter forms are quite valid.[5] New research related to inventory length, analyzed for STAGES data, is summarized later.

The STAGES Matrix

The STAGES Matrix is a new model that describes the stages of human perspectives from birth to the latest levels of human development investigated by research. One of the innovations of STAGES is the use of parameters for describing developmental stages. These are underlying attributes that lead to development. Below is the STAGES MATRIX which shows the sequence of patterning of the parameters of human consciousness across 12 levels (or 6 person perspectives).[6] These parameters are arrived at by asking 3 fundamental questions, as shown in Figure 1. We refer the reader to other papers, including Barta's "Psychological Application of the STAGES Model" in this issue, for a description of The STAGES model.

The STAGES General Protocol: Stems and Quadrants

Above we mentioned the notion, articulated by Kegan and Loevinger, that the holistic triangulation of contexts needed to measure one's general "center of gravity" should include subjective, objective, and intersubjective (I/we/it) contexts. O'Fallon has extended this notion to use Wilber's four-quadrant model: I/we/it/its, where the objective domain has been split into individual and collective objects (matching the subjective domain's split between individual "I" and collective "we").[7] Thus O'Fallon's protocols are designed to have a relative balance of stems representing each of the four quadrants. The quadrant categorization of stems is approximate, and is not expected to have a strong influence on the nature of completions – i.e. and subjects can respond to any of the stems in ways that emphasize any of the quadrants.[8] (Preliminary research is inconclusive RE whether stems categorized in a given quadrant tend to elicit responses from that quadrant – more research is needed.)

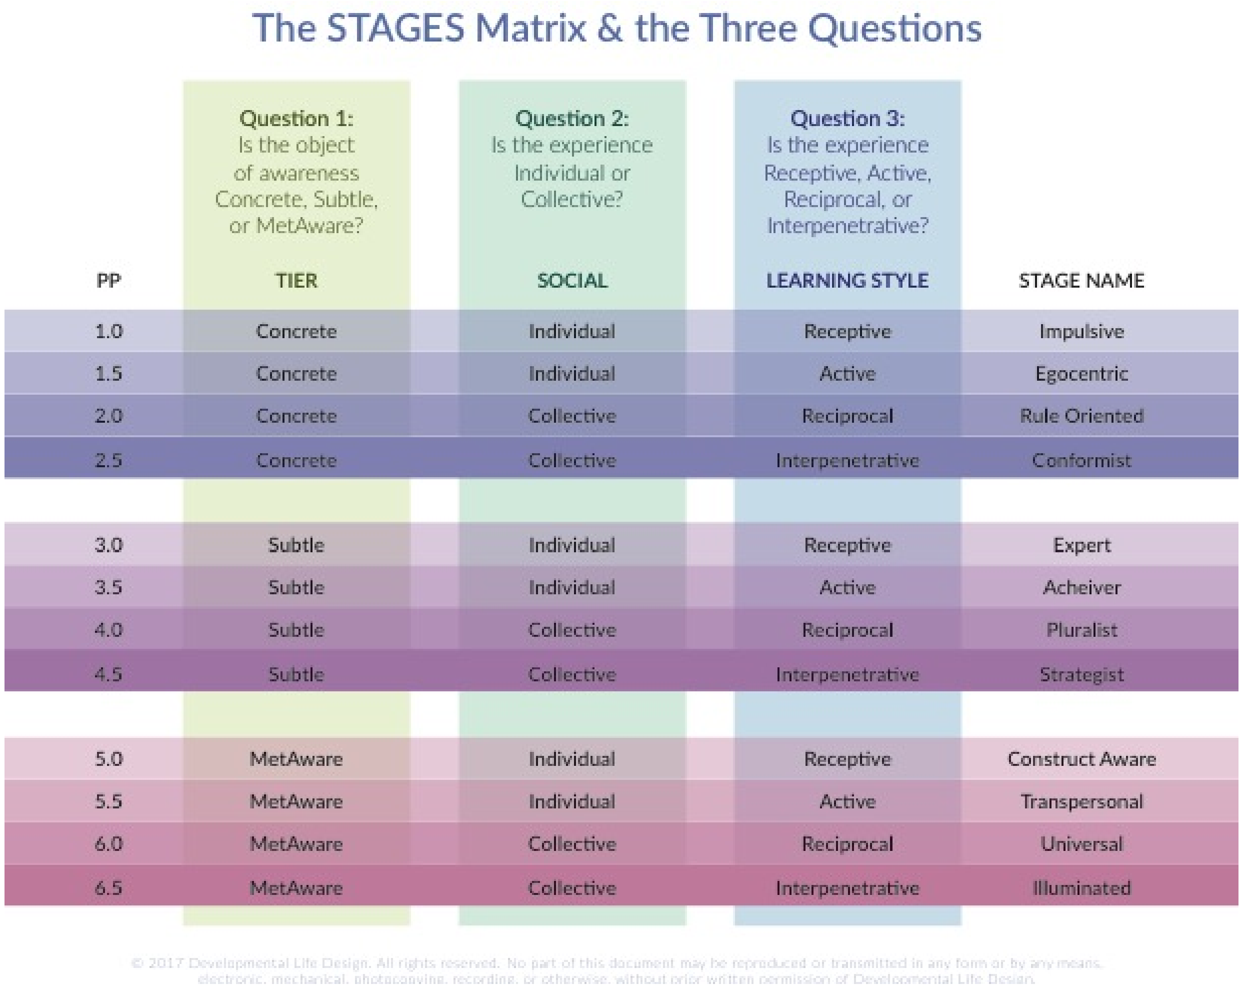
---

[3] Westenberg (2004, p. 603) claims that "Several studies suggest that the split-half reliability of the WUSCT…is about .80, and, if disattenuated for the greater unreliability of the two test halves, the correlation between the two halves approached unity."

[4] Browning (1987) used a short, 12-item, form in her study, and found that the short form has inter-rater agreement and internal consistency (alpha) "comparable to those reported by Loevinger" (p. 114).

[5] Holt (1980) also reports that the Cronbach's alpha for the 12-item test was .77, vs. Loevinger's finding for .91 for all 36 items, which is exactly what psychometric theory would predict for a randomly selected subset of 12 items from 36 (p. 915).

[6] The full model includes a third tier for a total of 16 levels, but the third tier is hypothetical and not supported by data.



The STAGES Matrix & the Three Questions

	Question 1: Is the object of awareness Concrete, Subtle, or MetAware?	Question 2: Is the experience Individual or Collective?	Question 3: Is the experience Receptive, Active, Reciprocal, or Interpenetrative?	
PP	TIER	SOCIAL	LEARNING STYLE	STAGE NAME
1.0	Concrete	Individual	Receptive	Impulsive
1.5	Concrete	Individual	Active	Egocentric
2.0	Concrete	Collective	Reciprocal	Rule Oriented
2.5	Concrete	Collective	Interpenetrative	Conformist
3.0	Subtle	Individual	Receptive	Expert
3.5	Subtle	Individual	Active	Acheiver
4.0	Subtle	Collective	Reciprocal	Pluralist
4.5	Subtle	Collective	Interpenetrative	Strategist
5.0	MetAware	Individual	Receptive	Construct Aware
5.5	MetAware	Individual	Active	Transpersonal
6.0	MetAware	Collective	Reciprocal	Universal
6.5	MetAware	Collective	Interpenetrative	Illuminated

Figure 1. The STAGES Matrix.

In 2016 O'Fallon revised Cook-Greuter's sentence stems by changing 9 of the original stems to new ones to achieve a relative balance among the quadrants. Adjustments were also made because some of the original Loevinger stems seemed outdated vs. 21st century western cultural norms. Table 1 shows the results. Of the 36 items, there are 8 stems associated with each of the four quadrants, plus 4 stems that are mixed-quadrant. Changed stems are indicated by bold text.

---

[7] And see a similar 4-domain model by Søren Brier (2013).

[8] The determination of stem quadrant is somewhat subjective, as judged by O'Fallon. We do not describe a method defining each quadrant here.

Table 1. General Inventory: Showing New vs. Prior Sentence Stems (changes in bold).

Order	Old Protocol	New General Protocol	Quadrant
1	Raising a family	Raising a family	LL
2	When I am criticized	When I am criticized	UL
3	Change is	Change is	UR
4	**A man's job**	**These days, work**	**UR**
5	Being with other people	Being with other people	LL
6	The thing I like about myself is	The thing I like about myself is	UL
7	**My mother and I**	**My co-workers and I**	**LL**
8	What gets me into trouble is	What gets me into trouble is	UR/UL
9	Education	Education	LR
10	When people are helpless	When people are helpless	LL
11	**Women are lucky because**	**What I like to do best is**	**UR**
12	A good boss	A good boss	UR
13	**A girl has a right to**	**We could make the world a better place if**	**LR**
14	The past	The past	LR
15	**When they talked about sex, I**	**Privacy**	**UL**
16	I feel sorry	I feel sorry	UL
17	When they avoided me	When they avoided me	LL
18	Rules are	Rules	LR
19	Crime and delinquency could be halted if	Crime and delinquency could be halted if	LR
20	**Men are lucky because**	**Business and society**	**LR**
21	I just can't stand people who	I just can't stand people who	UL
22	At times s/he worried about	At times I worry about	UR
23	I am	I am	UL
24	If I had more money	If I had more money	UR
25	My main problem is	My main problem is	UL
26	When I get mad	When I get mad	UR/UL
27	**People who step out of line at work**	**People who step out of line**	**LL, LR**
28	**A husband has a right to**	**A partner has the right to**	**LL**
29	If my mother	If my mother	LL
30	If I were in charge	If I were in charge	LR
31	My father	My father	LL
32	If I can't get what I want	If I can't get what I want	UR
33	When I am nervous	When I am nervous	UL
34	**For a woman career is**	**Technology**	**LR**
35	My conscience bothers me if	My conscience bothers me if	UR
36	Sometimes s/he wished that	Sometimes I wished that	UL, UR, LL, LR

Specialty Inventories: Description

As mentioned, the STAGES model allows for efficient introduction and experimentation with new sentence starters. O'Fallon and colleagues have developed a number of "specialty protocols." The first six of these, which replace 6 of the General protocol stems with theme-specific stems, have been validated for internal consistency: leadership, love, education, and climate change, psychological reflection, and a children's version of the SCT. Reliability analysis results are in the Results section later.

These spaciality inventories were developed separately and at different times between 2016 and 2020. With each specialty inventory, we worked with a consultant who specialized in that domain. We worked with that consultant to design 6 stems targeted at that domain, and in deciding which of the 6 General inventory stems should be replaced. Through this process we maintained the goal of having adequate stem representation among the four quadrants. Sometimes stems were spot-tested on a small number of subjects to check for potential problems (such as common misunderstandings), before the final set was decided upon.

Why create specialty protocols? We are testing the person perspectives that people take on these different areas. For example, what is a first, second, third, fourth, fifth, sixth person perspective on leadership; on love; on education; on climate change? For example on the Love inventory Britt and O'Fallon were able to categorize the specific ways that people at each person perspective understood the topics of love. In the climate change area this might be helpful in planning, policy decisions, or communications that are meaningful to various audiences. Specialty inventories are created for several reasons:

- Quantitatively, they allow a researcher or leader to gauge meaning-making (developmental) levels for a specific theme, for specific populations or sub-populations;

- Qualitatively, they allow for research into the concepts and themes by which individuals understand some domain, e.g. climate change;

- Finally, they allow for the wording of an assessment to appear more familiar or comfortable for given test-taking audiences. For example, if one is assessing employees in an organizational transformation research project, one may want to remove questions about parents or personal relationships which may strike the subjects as too intrusive.

Table 2 shows the new stems designed for each of the six specialty inventories we validate below: leadership, love, education, psychological reflection, climate change and a child inventory which is given orally. In addition, we are currently working with domain experts to design additional specialty protocols in these areas: relationships, religious beliefs, spirituality, money, hope, dementia, ethics, and parenting.

Table 2. New stems for the specialty inventories.

Inventory	New stem
Leadership	A good organization
Leadership	These days progress means
Leadership	Working with other people
Leadership	We could make organizations better if
Leadership	When developing strategies...
Leadership	These days, a career
Leadership	A good leader
Love	Love changes when
Love	Loving other people
Love	Love
Love	Business, society, and love
Love	When I am in love
Love	My main problem with love is
Education	These days, teaching
Education	My students and I
Education	A good educator
Education	Education and society
Education	Students who step out of line
Education	A teacher has the right to
Climate change	The environment
Climate change	Climate change is
Climate change	Regarding climate change, I
Climate change	My biggest concern about climate change
Climate change	People who deny climate change
Climate change	Actually, climate change...
Psychological	My friends and I
Psychological	A healthy person
Psychological	Sex
Psychological	Psychology and society
Psychological	An intimate partner has the right to
Children's	My family
Children's	Grandparents
Children's	These days, school
Children's	My parents and I
Children's	A good child
Children's	When they didn't let me join in
Children's	Bullying could be stopped if
Children's	Children and parents are lucky when
Children's	Children who step out of line
Children's	A parent has the right to
Children's	A child has the right to

The six validated specialty inventories came about as follows:

- The Leadership/organizational/business inventory was initiated by John Wood and Tamara Androsoff, PhDs, an OD consultant and coach who works with the STAGES model – with the goal of including sufficient stems addressing leadership and organizational issues.

- The Love inventory was pioneered by Marj Britt PhD, who is a Unity minister who became interested in the STAGES developmental model. Marg’s specialty is the area of personal and spiritual manifestations of Love, and she wanted to create a Love inventory.

- The Education inventory was initiated by Abigail Lynam, a college professor who teaches courses on educational theory, sustainability, and developmental theory.

- The Climate Change inventory was initiated by Gail Hochachka, a researcher in the area of Climate Change, who used the new Climate Change inventory in her dissertation study (see her report in this journal issue).

- The psychological reflection inventory was initiated by Mark Forman PhD and Kim Barta, MA. Both psychotherapists. It removes stems added to the General protocol about work and society, to maintain a focus on psychological/therapeutic themes.

- The children's inventory was co-created by Jennifer Haynes, Kim Barta and Terri O’Fallon. Jennifer is the principle of the integrally-informed Brisbane Independent School working with children from preschool age through Junior High, approximately. It is mean to be administered orally to children in that age range.

Method: Reliability assessment

As mentioned above, unlike prior models, the STAGES theory and scoring method allows for easy substitution of new stems. However, for any new protocol, one must establish the new stems, each and as a whole protocol, maintain psychometric validity. We assess the reliability of the SCT using the standard Cronbach’s Alpha measure of internal consistency (George & Mallery, 2003). A commonly accepted rule of thumb for describing internal consistency is as follows (IBID):

Table 3. Cronbach's Alpha Interpretation.

Cronbach's alpha	Internal consistency
$\alpha \geq 0.9$	Excellent
$0.9 > \alpha \geq 0.8$	Good
$0.8 > \alpha \geq 0.7$	Acceptable
$0.7 > \alpha \geq 0.6$	Questionable
$0.6 > \alpha \geq 0.5$	Poor
$0.5 > \alpha$	Unacceptable

Our statisticians determined that a sample of 20 surveys was sufficient to validate the reliability (internal consistency) of any new protocol.[9] Later we will give the reliability metrics for each of six new inventories (protocols) that have been designed and tested. But first we report on the reliability of the General Protocol, upon which the specialty protocols are based.

Following inventory design, we worked with the specialist to recruit 20 or more volunteers to take the assessment. Diversity of backgrounds and demographic characteristics was intended, but not strictly monitored. Surveys were scored by a certified STAGES scorer using the standard scoring manual/method. Then our statisticians ran the internal consistency statistics on the data set. In all cases, as reported below, the first version of the new inventory was satisfactory – i.e. there were no outlier stems that needed to be re-designed.

In the results for each inventory, we show the Cronbach's alpha for the inventory as a whole, for the inventory without the new stems, and for only the new stems. Note that Cronbach’s alpha values are naturally higher when there are more stems, and values for different numbers of stems are not directly comparable. That is, the internal consistency for 6 stems is always lower, but this does not necessarily mean that the items are worse then the other items. One would have to compare Cronbach’s alpha values between the same number of items for a direct comparison.

There are two additional types of psychometric analysis possible with each new inventory. One removes each item in turn, and checks the Cronbach's alpha of the remaining set of 35 stems – repeated for each of 9 new stems. We decided to only use this analysis when the overall reliability score is low, to check on outlier stems, but we have not needed to do this thus far. In addition, our statistician reports include a Spearman correlation dendrogram (Sokal & Rohlf,1962) that can be used to reveal hierarchical clustering patterns, i.e. similarities or correlations, between stems. These reveal in general that there are no outlier stems, and we have not yet used these analyses for deeper interpretations, so we do not include them in this paper.

Results

The General Inventory

Table 4 shows results of assessing the internal consistency of the new (now standard in the STAGES assessment) General protocol. It was validated vs. the prior "old" protocol. We compared 940 surveys based on the old protocol with 351 based on the new protocol.

Table 4. Cronbach's Alpha for New (General) vs Old protocol.

	Old *(N=940)*	**New** *(N=351)*
All 36 stems	0.98	0.97
Common stems	0.97	0.96
Changed stems	0.91	0.89

---

[9] Our statistical consultant for this project is Moni B. Neradilek from The Mountain-Whisper-Light Statistics in Seattle, WA.

In a test of removing each item and checking the Cronbach's alpha of the remaining set of 35 stems, repeated for each of 9 new stems, the resulting value varied from 0.9688 to 0.9692.

In related research reported on in this journal issue ("Investigating the Validity of the Ogive Aggregation Method, Including the use of Rasch Analysis, for the Sentence Completion Test and the STAGES Model") we use item response theory to assess overall reliability of the test, and look for item outliers (see subsections "Test length" "Item difficulties and item standard deviations", "Overall test strength," "Item discrimination," and "Summary/fit table; and discrimination strata"). These results reiterate the high reliability scores for the full inventory, and the acceptability of each individual item, as indicated above. (However, the analysis does show that the "I am" stem stands out as being the least correlated with other items.)

Conclusion. The overall internal consistency of both the old and new general protocols as measured by the Cronbach’s alpha statistic was excellent (0.98 and 0.97, respectively). The internal consistency of the changed stems in the new protocol was good and only slightly smaller than the internal consistency of the changed stems in the old protocol (α = 0.89 vs. 0.91). Through the method of deleting each new stem one at a time, we confirm that each new stem does not effect the overall consistency of the protocol.

Specialty Inventories: Reliability

Next we describe reliability analysis of the six new ("specialty") inventories: leadership, love, education, psychological reflection, climate change, and a children's inventory For the children's inventory, 53 children, age range 4-13 enrolled in a progressive elementary school in New England, gave verbal answers to in-person prompts; recordings of their answers were transcribed. The data is shown in Table 5

Table 5. Cronbach's alpha internal consistency values for specialty protocols.

			Cronbach's alpha			
Domain	**Leadership**	**Love**	**Education**	**Climate Change**	**Psych**	**Children**
N in study	32	20	20	32	17	53
New stems (of 36)	6	6	6	6	5	11
α All 36 stems	0.97	0.95	0.95	0.96	0.92	0.88
α General prot. stems only	0.96	0.94	0.94	0.95	0.90	0.85
α New stems only	0.85	0.82	0.83	0.82	0.80	0.63

Conclusions: For the five specialty inventories excluding Children's:

- the overall internal consistency was excellent (α 0.95 to 0.97).
- the internal consistency for the new stems as a group was good (α 0.80 to 0.85).
- For the Children's inventory:

- the overall internal consistency was good (α 0.88).
- the internal consistency for the new stems as a group was questionable (α 0.63).

Overall, these results not only show evidence about the reliability of the particular specialty inventories, but it is also show evidence that the SCT is quite robust to the addition of new stems, assuming they are well-written. It also gives evidence that even a short test containing only six specialty stems would be a psychometrically reliable instrument.

The Children's protocol is a special case. First, there were almost twice as many new stems as the other specialty inventories. Second, the assessment was done face to face and verbally. Third, the pre-existing (general protocol) stems by themselves show a much lower alpha (though still "good") vs. the other protocols, indicating that there was probably much more variation in the children's responses than in adults' (see O'Fallon's paper on the Children's protocol in this issue). Thus, though the alpha of the new stems by themselves was unacceptably low, it is not clear whether this was because of the nature of the stems or the nature of the subject population.

Inventory size analysis

Above we summarized prior research suggesting that the SCT worked well with shorter versions. Here we evaluate inventory length variation with the STAGES assessment particularly.

A shorter, 16-stem, inventory. Given the strong results on the reliability of the STAGES SCT mentioned above, we decided to experiment with a shorter inventory containing 16 stems. This gives us an inventory that subjects can take in half the time, which is important for some applications.

We selected 16 stems from the General inventory which we had previously gotten a high Cronbach's alpha on. We chose sentence starters that would point to each of the four quadrants. The stems were: 1, 2, 5, 6, 8, 18, 19, 20, 21, 23, 25, 27, 28, 30, 34, 35 (from Table 1). The Cronbach's alpha for the 16-item inventory (0.98) is in the "excellent" range.

Cronbach's-Mesbah analysis. The paper "Investigating the Validity of the Ogive Aggregation Method, Including the use of Rasch Analysis, for the Sentence Completion Test and the STAGES Model" (Murray, this issue) includes additional analysis related to test length, which we summarize next. Figure 2 shows a Cronbachs-Mesbah curve illustrating the Cronbachs-alpha score for successively fewer test stems (with the worst correlated items removed first). It shows that for a half-item test the reliability is still excellent (.95); and that even with 10 stems, the SCT has very good reliability (.92); and that even at 5 stems the reliability is quite good (.85).

From a purely statistical perspective, the SCT doesn't need so many items (assuming this pattern was also true of the WUSCT or MAP variations of the SCT – though we don't have item-level data for those). However from a qualitative research agenda, and for coaching and debrief purposes, a full set of 36 responses is important for identifying themes and patterns in the detailed reports and coaching sessions given for individualized SCT assessments. Thus for the purposes of sharing qualitative information, and not just a final statistical score, the longer inventory is preferable.

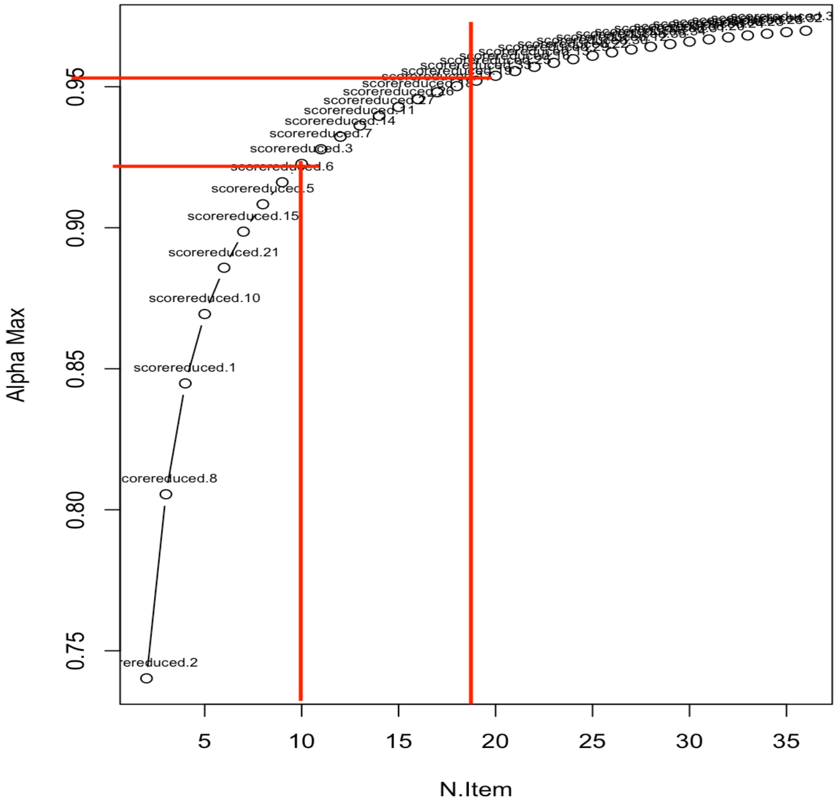

Figure 2. Cronbach-Mesbah curve of alpha vs. number of items.

Conclusions

Over the past 4 years we have experimented with the efficient and effective adaptability of the STAGES SCT Inventory. Beginning with the alteration of the General Inventory, we learned that we could change up to 9 stems all at once in a 36 item inventory, and still have very high internal consistency. This prompted us to experiment with other uses of this process and the idea of the specialty inventories was born.

The resultant findings indicate that the STAGES model allows for efficient introduction and experimentation with variations on the SCT, including new sentence starters and length variations. O'Fallon and colleagues have developed and evaluated "specialty protocols" in these domains: leadership, love, education, and climate change, psychological reflection, and a children's version of the SCT. Most of the specialty protocols replace 6 of the General protocol stems with theme-specific stems. However generally we have an indication that we can change up to 9 stems as depicted by our research on the new General inventory. We are now experimenting with variations on this theme.

We have shown results for internal consistency studies of (1) the STAGES General Protocol, (2) Six specialty protocols, and (3) a shorter 16-item inventory. We have shown that for all of these inventories there is excellent internal consistency (excluding the special case of the Children's study).

Our research not only gives evidence about the reliability of the particular specialty inventories, but also shows evidence that the SCT is quite robust to the addition of new stems, assuming they are well-written.

Our research also shows that the STAGES assessment (and the SCT in general) is psychometrically valid for much shorter inventories, as low as 10 and even 5 items for certain applications.

These statistical results give us an underlying confidence that these variations on the regular inventory are internally consistent.

Once we have this assurance we then do the qualitative research that allows us to extract meaning from what the test takers actually say. For example, we have done qualitative research on the Love inventory. We selected all the Love stem scores at each developmental level and created categories out of their responses. The resultant understanding points to the perspectives people take on Love at each developmental level. As well we can see the evolutionary trajectory on the test takers views on love. The addition of the qualitative research can support curriculum development, policy development, planning, and particular interests of various audiences.

Future Research

Based on the research on adapting the General inventory in length and specialty there is further research we aspire to.

1. We are currently working with domain experts to design additional specialty protocols in these areas: relationships, beliefs related to a specific religious tradition, spirituality, money, hope, dementia, ethics, and parenting.

2. Since we can see that there is a variation from 5 to 9 stem changes and still maintain internal consistency, we will be experimenting with variations of these numbers for other specialty inventories.

3. Since the 5-9 stems isolated from the general inventory still have a “good” internal consistency we will look into using only the specialty stems to indicate the developmental perspectives that people take on the specialty only. This would involve much shorter inventories for people to take which might bring a research advantage, if there is enough material to do qualitative research.

4. Once the quantitative research is complete, qualitative research yields more useful and practical day to day value for our clients. Thus we will be continuing to do serious qualitative research on all specialty inventories and to perfect the relationship between the

quantitative and qualitative interface for the benefits of our services to others. As well, we will look into how to develop curriculum, planning, policy, and service to each specialty area and the audiences that resonate with them.

Exploring Integral Polarity Practice, in relationship with the STAGES Matrix

Trish Nowland[1]

A conversation with John Kesler[2] and Thomas McConkie[3] with Tom Murray and Trish Nowland

Introduction

This piece is written by myself as a participant in a conversation among John Kesler, founder of Integral Polarity Practice (IPP); Thomas McConkie, John's first IPP successor, and executive director at IPP Institute, as well as founder of Lower Lights Sangha in Salt Lake City; and Tom Murray who has worked with Terri O'Fallon in the context of STAGES as discussed below for about six years. Tom and I have also participated in some of John's IPP workshops over the last 10 years, and are Generating Transformational Change program graduates, as is Thomas. The dialogue was organized by Tom in mid-November, 2019, in the context of the Special Edition of Integral Leadership Review focused on the STAGES model. I've also benefited from co-curating a space for folks in the South Pacific to share in IPP as facilitated by John and Thomas, as you will read below, on occasions since 2012.

---

[1] **Trisha Nowland** presently convenes Sydney Integral, and has supported the Integral Polarity Practice South Pacific community since 2012. With diverse interests spanning mathematics, philosophy, and psychology, she has recently moved on from a 15-year career in information systems in finance to begin practice as a psychologist, working with communities at the margins in Sydney's suburbs. She is a Generating Transformational Change (GTC) graduate, and has in the last year completed a doctorate which developed a set-theoretical model for integrating qualitative and quantitative methods in psychology research. She currently works as a researcher in Australia's non-profit sector, and remains as a passionate reader in continental philosophy, psychoanalysis, Marxism, and Vajrayana Buddhism.

SOME RIGHTS RESERVED

Integral Polarity Practice (IPP) is a unique awareness, life, and group practice designed to support a person in “waking up” and “growing up”, as well as in developing healthy integration of body, emotions, mind, and Spirit. IPP itself integrates developmental theory, meditative techniques, virtue practices, and voice dialogue. Developed by John Kesler, it is influenced by John’s experience with the Big Mind process, and the group facilitation of IPP will be familiar to anyone who has participated in Big Mind. John was one of the first to be certified as a large group practice facilitator by Zen master Genpo Roshi, the founder of Big Mind process. Big Mind is a participatory process that enables a person to access non-dual awareness and other transcendent states through sharing in collective voice dialogue, a Jungian therapeutic technique. In this process, a projected personification of particular qualities or attributes is encouraged to ‘speak’ from its perspective through the diverse voices within the group, providing an opportunity for individuals to interact with that perspective in a way that they perhaps never have before. The Big Mind Process may also be practiced one-on-one, or self-facilitated.

The appendix to this article has diagrams of the IPP stages and structure. IPP is also described at www.theippinstitute.com. The video recording of the dialogue that informed this article can be found at http://bit.ly/stagesippvid, with an audio-only version at http://bit.ly/stagesipp1.

John designed IPP using an approach to person-perspectives articulated by Susanne Cook-Greuter, Ken Wilber, and most clearly in Terri O’Fallon’s STAGES model. This work is itself a progression from earlier work by Suzanne Cook-Greuter (1994) on the ego development scale originally found in Loevinger and Blasi (1976). Also knitted in to IPP are perspectives from other spiritual traditions, including references developed from John’s own background as a Mormon bishop. The practice stands in some ways as a meta-lineage framework, incorporating qualities and virtues that are relevant to the practices and principles inherent in an array of spiritual/perennial traditions. Ultimately, John describes that IPP’s principles and structure flowed out of him incrementally over a number of years, in the context of facilitating others in practice, as well as through his own meditation and life practice. In what follows, we trace the structure of IPP, its qualities as a voice dialogue process, the specific connections to and divergences from Terri O’Fallon’s STAGES model, some brief comparisons to other similar offerings in the space and finally looking to the future opportunities that speak back to us at this point. We start firstly with the question, for those who have not experienced it before - what is Integral Polarity Practice?

The Basic ins and outs of IPP

The figures at the end of this article show the IPP model diagram. The first shows the IPP level sequence, and the second shows a detailed view of the sub-processes for one of the levels. The development of IPP included developing primary polarities that mark something of the resolution to primary developmental challenges that are implicit in any single developmental stage, similar to Erik Erikson’s developmental crises (Erikson, 1959). In Erikson (1959) the model of ego development involves an individual navigating opposing forces that are proposed as present at each developmental level, to achieve what Erikson describes as “potencies” (see Capps, 2014). The polarities in IPP have organically emerged as described above, and have changed through time. These changes have been both consistent with and yet are distinct from the evolution of the STAGES model through time. For example, the earliest stages of the

STAGES model are not as well articulated as later stages, as the development of this model has relied primarily on linguistic analyses of responses from adults, involving responses by participants to sentence stem completion tests, using written language (see more detail on this below). Through IPP, John and the participants in the IPP process have made possible an articulation of pre-verbal polarities, which can be directly connected to sensory experience (for example, expansion and contraction, and focus and openness, at the lowest levels of ‘0.0 Life’ and ‘Mind’, respectively).

IPP borrows stage designations from the STAGES model: 1.0, 1.5, 2.0, ...6.0, 6.5; for the 1st through 6th Person Perspectives (PP) defined in STAGES. It also includes a 0th PP (not explicitly described in STAGES) and a Unitive tier (7th and 8th PP, not shown in the IPP figure; which are in advanced versions of the STAGES model). Perusal of the ‘Polarity Overview’ graphic also reveals an important aspect of IPP beyond its articulated developmental structure and the use of polarities - this is the notion of a still point, from within the specific developmental polarity. This still point becomes an orienting viewpoint for that specific developmental level, and the still point itself has a dual or polar aspect - it reflects bringing the energy of the highlighted polarity into stillness, as well as a deepening of the potency which may be achieved in virtue of recognition of the negation or emptiness of the potency. What this means is, to traverse a developmental polarity well, we must be able to see into and experience both the negation and emptiness of that developmental level, as well as have a sense of experiencing the fullness of the essence of a polarity.

The practice is intended to help folks create a peaceful center, and to access their deepest wisdom, compassion and insight, and to live a fulfilled life. It is intended as a complement to other practices and traditions. Another way to say this is that it represents a meta-lineage framework - supporting how traditions cultivate centeredness, and basic human virtues. IPP makes visible possible virtues related to all developmental levels, and allows a deeper understanding of the specific virtues that traditional lineages cultivate. Since the IPP patterns for working with any polarity are identical, these same patterns can be applied to the endless polarities we experience in life in addition to the primary developmental polarities – in the process of waking up, growing up and becoming more integrated and effective in the world.

Description of IPP in Practice

Both John and Thomas note that there is an incredible amount of rich material available in the earlier polarities, and hence many of the group practices to date have oriented to these structures. As a member of the ongoing South Pacific IPP group which has practiced through the southern hemisphere winter, usually on a fortnightly basis since about 2012, we can say that about 80% of our sessions have been on polarities at 4.0/Context Aware’, and below. Concrete or earlier polarities tend to be information-rich or ‘juicy’ - much of our psychological shadow, or unintegrated aspects of our persona may be deposited in the concrete tier (0th, 1st, and 2nd PPs) and contemplation on this developmental range offers repeated insights. We can work meditatively with these in group and also as life practices - similar to working with weights - some exercises are much more difficult to access and perform, but vitally, repetition and engagement of the limbs builds muscle. The early polarities seem to be the ones where our individual experiences are most sharply and clearly differentiated, where insights gleaned from individual or group practice allow us to literally ‘see’ things differently. In the voice dialogue practice, we find it is often the case that the other side of the polarity becomes available from literally within the practice, embracing the first side. What becomes possible in this moment is witnessing the way that the terms and experiences mutually define, refine, and permeate each other. This leads in an experiential sense to appreciating the still point, the gift of literally presencing an embodied appreciation of the emptiness and fullness and ultimate unity of both sides of the polarity, at the same time.

It is possible to notice a pattern with the still points in the IPP chart, with an empty node, which is typically the location of the absence of the developmental level (for example, ‘no achieving’ for 3.5/Achiever), and then a fullness node, which is a transcending of that developmental level, for example, ‘completion’, for 3.5/Achiever. These mark a foundation-to-causal shift, for these experiential states. The still points are described by John and Thomas (and are experienced as a participant in an IPP session) as an experience of causal awareness – the subtle dance of the polarities and/or the concreteness of the terms becomes able to be inhabited from a place of utter stillness. The unification of the poles creates a quality of non-duality; the unity of the fullness and the emptiness of the still point a more complete non-duality; and then a collapse of one’s witnessing awareness into that, an even more complete non-duality. All of this is part of a protocol for working deeply with any polarity. What is invited is both a witnessing and an embodiment experience, founded in a view of mutuality of difference, and indistinct union, both across polarities and across the perspectives that are introduced in real-time, by participants with the ultimate collapse of the witnessing.

The particular trajectory for experience nurtured in this dynamic is informed by the Big Mind non-dual experience made available in the original teaching of Genpo Roshi, but now contextualised for each developmental level. Dwelling in the experience of the still points gifts one with the accompanying experiential appreciation of that stage’s virtues. The virtues are an unfolding which expresses the quality of the relationship for the specific polarity in question. There is always a primary virtue of Becoming (with Eros energy) and of Doing (with Agape energy) which arise out of each still point. For instance, the fullness still point, Transcendent Abundance, for the polarity of seeking (desire/aversion) automatically yields the Virtue of Becoming of Transcendent Gratitude, and the Virtue of Doing of Transcendent Generosity.

This is meant to facilitate deep engagement with wellbeing, and a deeper embodied understanding of the polarity itself. What unfolds is something that, on the surface, is a seeming shutting down the whole function of the polarity (i.e. if I only feel Abundance and Fullness and/or the emptiness of non-seeking, I have no need to desire or move away from anything). This polarity of seeking sits as a foundational polarity of our everyday being - we learn, our whole lives, and seek to move towards or away from things - essentially always coming from a place of deficit. In practice, if we are present in the moment, and allow in a sense of an absolute Abundance, it is possible to see more clearly what is appropriate to seek from our deepest place of Wisdom and Compassion. We are both more free to seek, and to not seek. This facilitates total presence with either state, without being locked in ego defenses and ego needs. The still point is always a place of Beingness, in this place of availability of the whole spectrum of one’s being, one can find the source of wisdom and awaken through the portal the more encompassing aspect of the more-than-self.

As Collective Voice Dialogue

IPP can serve in the modes of both a life practice (something supporting deeper engagement in everyday activity), and as an awareness practice that builds specific skill-sets in attending within distinct perspectives, which comprise their own polarity to be fully integrated. In a group setting, the process of voice dialogue lets us access the polarities more deeply. There is a freedom to acknowledge how much of a particular polarity side would be medicinal in any given circumstance. For instance, personal agency in the territory of any stage (or polarity) is deepened in a distinct way in a collective setting (vs. individual). We may see more clearly in the collective what it is possible to do, individually. Thomas describes drawing on IPP in working with distinct aspect of his personal relationships in life practice, drawing out perspectives that otherwise may persist as irritations of a sort to the psyche - those qualities of another that we're both drawn to, and distanced by. Everything below one's center of gravity represents a therapeutic opportunity - a re-encounter – and bringing one's higher awareness in offers the opportunity of embodying the very foundations of one's Being with increasingly transcendent sensibilities.

John notes that the virtues of the still points emerged initially from intuition, and then groups in dialogue settings shared feedback about them - so the model is a product of both individual and collective experience. The virtues which emerged out of the first eight perspectives pretty much align with the traditional virtues as well as positive psychology strengths - collective wisdom seems to arrive in the field of collective experiencing - the practice framework gives us something to guide us, but there is something dynamic that seems to occur in the shared space. In groups, by making the dynamics visible, with a basic understanding of the territory, we are more likely to notice and detect virtues when they are present in the everyday world. Even subtle presencings can be attuned in a new way in conscious awareness, via the practice.

From a collective practice standpoint, it can be noted that everyone has blocks which occur in different ways. Approaching the virtues of IPP can help us to actually access the still point, even if there is a specific block around one of the polarities, and find a way to navigate then to the less visible pole. The virtues, still points, and polarities then are mutually reinforcing. Also of note is the sense that vices can emerge when one is blocked from a still point or virtue - for a mapping of these, it is possible to consult the more detailed charts (see 'Polarity Charts' at the bottom of this page: https://theippinstitute.com/resources).

From the facilitator's perspective, it is possible to note that often a particular voice will speak up in a group voice dialogue session. Thematic consistencies from cross-group experience unfold which the facilitator can then draw upon, in practice. Facilitators can support/induce opportunities for causal state experience, which were not previously available in the room. The structured personality system marked by the STAGES and IPP softens in this presence, so the tail can wag a large dog, in a way. There can be found an amplified field-effect, and the wisdom that is already available in the collective or group is noted by John and Thomas as tending to 'spout out', and make itself known.

Historical Relationship between IPP and STAGES

John developed the essence of IPP initially by framing developmental polarities related to stages used most often by Ken Wilber and then through an encounter with Suzanne Cook-Greuter's work with the Leadership Maturity Framework. Note that Beena Sharma has since developed a version of Suzanne Cook-Greuter's developmental training called "Integrating Polarities" (developed independently of IPP; see https://integrallife.com/integrating-polarities-training/). More is described about the link between Beena's work and IPP, below. For IPP, John became acquainted with Terri O'Fallon through Suzanne. Terri was formalizing the STAGES model at that time, working within the Pacific Integral (PI) organization. John was invited by Terri to be one of four individuals including Terri to engage in the first scoring of sentence completions using the STAGES methodology in a research context over a period of two years (that version eventually become known as the MAP). John was one of the first to be certified in STAGES scoring and debriefing. IPP does not purport to represent STAGES fully, but there is an intentional close alignment - including the specific focus on more granularity in the meta-tier than in other developmental models.

Meta-elements that Span IPP and STAGES

"Integral Thematic Practice" was the original early name of IPP, and the early focus of the practice was oriented toward five themes referred to as ground, concrete, subtle, causal and integration phases, which manifest in states, stages, types, and modalities of life and spiritual practice, etc. The STAGES model today carries this thematic throughout the patterns in the tiers. John notes for instance that the 5 Buddha families of personality types carry the same themes (see https://tinyurl.com/vjm8yhk) and that they are otherwise pervasive in various aspects of many Buddhist and Vedantic schools. These five themes turn up in multiple interpenetrating dimensions beyond our conscious ability to integrate, and so we find ourselves in a holistic aesthetic of integrating these interpenetrating thematic cores – one might say in an ongoing jazz composition of life. Over time John noticed that the pervasive thematic elements of the practice are most accessible to only advanced practitioners, and changed the name of the practice to highlight its most obvious structural element: polarities. Yet these thematic elements are central in framing a new full four stage tier prior to 1.0 and a more detailed four stage unified tier, which are elements of what might be called IPP 2.0 to be shared in late 2020 or early 2021.

Another theme that traverses both STAGES and IPP is an appreciation of both the evolutionary and "involutionary" modalities of awareness. Evolutionary or ascending through Eros is associated with development and greater complexity and oneness, but practicing and embodying the involutionary current through Agape from a prior no-dual unity makes possible the awareness that we ourselves are expressions the divine or the absolute. In involutionary terms, polarities emerge from that prior unity, which make obvious experientially that one pole is inherent in the other (in a sense the poles arise out of the still point, in contrast to seeing the still point emerge from the relationship between the poles). An example of this in the involutionary practice is that the virtues of Transcendent Joy and Transcendent Sorrow both arise from unqualified Transcendent Love and one cannot exist without the other. Christ coming to be on earth is a symbol of both Transcendent Joy and Transcendent Sorrow, in Love. In the involutionary practice this just flows in the person's awareness stream, rather than being articulated, as appreciable differences. In this way, IPP helps guide an experiential understanding of the broad possibilities that accompany the flow of Love, for example. The involutionary practice presumes stabilizing in non-dual awareness and is hence an advanced practice, and the embrace and oneness of the Eros and Agape, of evolution and involution are the final polarity practice of IPP.

Differences between IPP and STAGES

We can note that the most foundational polarities in IPP (0.0 and 0.5) and as further expanded and developed in IPP 2.0 are not found in the STAGES model and yet are implicit in STAGES theory. For example, the foundational 0.0/Life polarity is one of physical expansion and contraction. This works with the concrete poles as well as subtle flow between them, into an experience of the causal still point of profound relaxation. This is a very direct example of where access to states is available all of the time, and these states became structural elements of the polarities at the different stages in STAGES. It may, for later levels, be a requirement of development to actually continue to hold the polarity and work with its wisdom from multiple perspectives as relevant to the stages, but the experience of existing in a way calibrated by polarity such as that of physical expansion and contraction is available at all levels.

The development of these earliest polarities, prior to the development of verbal and linguistic skills, speaks to and for our experience simply as beings, which we share with all animals and yet by bringing our highest awareness to these polarities they provide a framework for profound embodiment, enrichment and growth. Drawing on Vedantic understandings of physical functioning and sentience, we can note for example that expansion and contraction need to be available for consciousness to come into living, as is available even for one-cell organisms (Bainbridge Cohen, 1993). The basic pattern of expansion and contraction is foundational for the most primitive of life forms, and is true even for plants. Bringing the highest awareness to this most foundational of experiences brings forth an opportunity to touch into the Ultimate, in terms of a unifying principle, something foundational for all grounded in the still point and the virtues of Transcendent Acceptance and Transcendent Life Force. *Both* IPP and STAGES allow for this fluidity - i.e. they allow one to be informed of, and to engage in, a profound mystical experience - incredible discoveries are continually available in those spaces. In following Loevinger, Cook-Greuter and Kegan, the STAGES approach tends to address “meaning-making” as it manifests explicitly and verbally, vs. the more experiential non-verbal core of the experiences reached in IPP.

Kim Barta, who runs STAGES International with Terri O’Fallon, has had a vital role in bringing Terri’s work alive in these early polarities, and includes the 0.0/Life and 0.5/Seeking polarities in his presentations. John notes that across developmental psychology as articulated in integral spaces, there remains a bias with respect to an imputed primitivism of earlier stages. Because of the orientation to adult development and linguistic skills described above, it is easy to see how the bias has come about, whether it is described in terms of shift to orientation to broadening out later perspectives, or straightforward negation or neglect of these levels as they can’t directly be accounted for in sentence completion self-report format. IPP gives a different view - so much information is available at these earlier levels - children, particularly for example, have access to a different kind of tuning in, which is appreciable among adults - this is a shared wisdom, across cultures. In participating in IPP we're returned to these more ancestral or earlier developmental experiences, to work our way forwards again, into experiences that can be supported by more complex neural development, or experiential awareness. This includes IPP polarities and practices which support on in transitioning into, fully integrating and transitioning out of four stages in the meta tier and four stages in the unified tier.

Apparent Divergence but Profound Complementarity of STAGES with IPP

On the surface IPP appears to be consistent with Loevinger's research, with no repeat of patterns through the stages. This is different from the STAGES model, which is built on repeating patterns, through rather than within the stages. So on first glance, the driving force or motivating energy for IPP, compared to STAGES, seems to be distinct. For example - for 3.5/Achiever, in STAGES the separation of poles for the perspective at that level is either/or, and subject/object. This is what the developmental model would prescribe. IPP sets forth subjectification/objectification as the key polarity at 3.5, and experience has shown that people at 3.5 experience that polarity in an either/or manner. However IPP show how this polarity can be experienced in a both/and manner at 4.0, in an interpenetrative way at 4.5, and beginning at 5.0 and especially 5.5 is experienced as a unity. This is what STAGES predicts and points to. We can say that the practice of IPP has a dynamic in it that habituates the participant to the practice of unifying distinct perspectives. John states it this way - IPP has been a beneficiary of experientially validating what STAGES points to. While STAGES predicts then that someone can see deep interpenetration of subtle polarities at 4.5/Systems Aware, through facilitation IPP gives an opportunity to encounter the habits and cultivation of awareness that supports the dynamics of 4.5/Systems Aware consciousness throughout the wholeness of being.

Another example of IPP inherently holding the patterns of STAGES is that in STAGES, successive emerging stages alternate in passive/active succession and reflect early to more mature expressions of moving from a ".0" stage to a ".5" stage. At the 1.0 stage, IPP sets forth agency/communion polarity as a foundational relational polarity. One cannot have a sense of self without an implicit other. The next polarity at 1.5 is control/submission, which brings the inevitable power realities into any relational environment. This pattern is repeated throughout the spectrum of primary IPP polarities.

Another aspect of IPP which is not evident on its face in the simple listing of the IPP polarities is that for instance, agency/communion is a subtle tier version of me/you or me/group which one would encounter when it first arises in the concrete tier. It is listed as agency/communion at 1.5 in the concrete tier because this is the earliest stage of that relationality emerges, but most IPP practitioners have a center of gravity in the subtle tier (3.0 to 4.5 person perspectives), and so the subtle tier version of the polarity is listed on the summary chart. Only in working through the underlying theory and advanced practice of IPP is it made clear that once a polarity comes on line, it has different manifestation at each tier of development. So for instance, what would be me/group in the concrete tier, is agency/communion in the subtle tier, and Witnessing/Worlds in the meta tier. This is all inherent in STAGES as well. IPP is simply a practice modality for these patterns. STAGES is certainly broader in scope and more theoretically complex in developmental terms than IPP, but where they overlap there is remarkable similarity.

Comparison to Other Systems – Polarity Management System, Pointing Out Way

Suzanne Cook-Greuter and Beena Sharma, mentioned earlier in reference to the Leadership Development Framework, have built on the Polarity Management System of Barry Johnson and have confirmed a set of polarities which are characteristic for each stage through 4.5. Beena is a master of this polarity model and has formalized her teaching of "integrating polarities" under the name of the Polarity Approach to Continuity and Transformation (PACT). PACT is not itself meant to represent the full developmental map articulated by Cook-Greuter and Sharma, but it is an extremely helpful approach and tool usable within developmental education, personal reflection, and in groups and organizations. Among other things, It provides support for achieving a 4.0-4.5 level of developmental complexity and related competencies for working with polarities in our lives and work. PACT is actually beneficial for some participants who are not as comfortable with paradox, in that it provides a clear system for navigating paradox, while IPP invites one more deeply into the experience of paradox and beyond.

A primary distinction between PACT and IPP is that PACT emphasizes working with the subtle dynamics of polarities, whereas IPP explicitly works with the concrete, subtle, causal, witnessing and non-dual state dimensions of every polarity in in the context of stages, types, lines and evolutionary and involutionary dynamics Sharing approaches and tools similar to Polarity Management and PACT is increasingly included in IPP Institute offerings because it helps people become familiar with polarities and comfortable with polar dynamics in a developmental and applied context before diving more fully into the deeper practice of IPP.

Practice with polarities within IPP requires comfort with paradox in concert with attentiveness to both spiritual awareness and meaning-making. One way of describing falling into the still point is that the human equivalently disappears into the Tao - non-egoic virtuous action is possible, if the individual is willing to let go of the self. Another comparable system discussed in our dialogue was Dan Brown's 'Pointing Out Way', a relational teaching facilitated by Dan Brown in a multi-day retreats that, through successive practice levels, induces a taste of awakening for participants. John noted that the involutionary current that is apparent in the Indo-Tibetan teachings tends to work with the idea of a self-structure, and levels of egoic assembly that accompany more solidified self-structures, breaking this down to provide the opportunity for an experience of awakening from the limits of what these are (see Epstein, 1996, for an accessible introduction to the connection between Western psychotherapy approaches to the self, and Buddhist principles, with respect to the ego). Notably, the Pointing Out practice stays in very close contact with Mahamudra teachings and Gelugpa lineage, as passed down to Dan during his meditation training. This is distinct from the work of IPP as a meta-lineage framework, which does not anchor directly to a specific tradition or lineage.

Conclusion in Brief

As we began Down Under to explore the possibility of engaging in regular practice spaces to delve into the experience of IPP, I remember having read Tom's and Terri O'Fallon's paper from Integral Review in June 2010, "A perspective on Kesler's Integral Polarity Practice". What was clear, in reading this paper, was the sense of profound depth, to this practice – in the words of Murray and O'Fallon, in the practice, there is a transmission along the lines of the experience in the moment of this just being "the tip of the iceberg". There is something available in the complexity and intricacy of what is held, by John and Thomas, where we find each other newly, together. If I bring to mind the most frequently repeated refrain from folks around Australia and New Zealand who have shared in the online experience, it is that we can't quite believe, often, that we have never met each other in person, and have never met John or Thomas, in person. We're nurtured into spaces, where we find ourselves, more deeply available perhaps, to others, and to ourselves. If there is one possible real-world realization that might unfold from the last line of that article, a quote from John that says this practice supports finding "the ever present sacred ecstasy and ordinariness of life", I believe it may be this; we're more able to know each other and ourselves, in this space. It is with wonder to turn towards what the possibilities might be that are represented, in IPP 2.0.

Luhmann`s Life Work and Tier Patterns:
The Analysis of Differences and Contingent Patterns

Roman Angerer[1]

Abstract: The article undertakes an archeological investigation into the writings of the German Sociologist and cybernetic Systems-thinker Niklas Luhmann. His writings spanning almost four decades of uninterrupted stage growth and text production are good fodder to dissect ruptures between and plateaus of semantic-syntactic structures called developmental stages. By this an architecture is exemplarily revealed that spans four Tiers including sixteen Stages with four subphases at each niveau of relative stability which sometimes is called Center of Gravity. The article is structured as an oscillation between genetic and structuralist phases that enrich Luhmann`s Life Work by multiple references to other thinkers at the integral and post-integral stages. The final section that then presents the complete model is also a critique of other developmental models specifically directed towards and suggesting critical revision of Terri O`Fallons STAGES model. This happens through introducing four common fallacies developmental models commit, when trying to appropriate the transcendental and phylogenetic realm preconditioning our conscious growth, through the contingencies of our very self-referential and themselves-thematizing observations. Additionally, in discerning between genesis and structure, descenders and ascenders, inside and outside perspectives and ultimately an Aristotelian and an Platonist Type of stage growth it is the attempt of a seamless intervention between both modes, uniting them and ultimately deluding them of their most prominent errors: the necessity of a first distinction mistaken for the creator and their ultimate purpose mistaken for the divine.

Keywords: Archeology, ego development, Nicholas Luhmann, semantics, text analysis, universal grammar.

Introduction

Basic Structure

The following article will offer a developmental view on Niklas Luhmann`s work. Luhmann was a German sociologist and social theorist. He is considered to be the most important German-speaking representative of sociological systems theory and socio-cybernetics. We will follow him through ruptures in his life and writings in an attempt “to establish, between so many different changes, analogies and differences, hierarchies, complementarities, coincidences, and shifts: in short, to describe the dispersion of the discontinuities themselves”, as Michel Foucault (1972, p. 175) lays down in his *Archeology of Knowledge.* However, despite Foucault`s doubt of deploying “two heterogeneous stages on either side of a split” (ibid. p. 175), these ruptures in Luhmann`s life and writings will be related to a linear sequence of stage growth.

This procedure is promising in at least two differential but interrelated ways, when it comes to improve adult developmental theory and its measurement: a) it will give more granularity to single stages by showing repeating patterns within the dispersion of discontinuities and b) by following these repeating patterns of differences and similarities and the related ruptures further differentiates within what Susanne Cook-Greuter (2010) called post-autonomous ego-development. These repeating patterns stem partially from the examination of Terri O`Fallon`s work and the attempt to dynamically deconstruct and reconstruct it within the written expressions of common people and famous Authors` lives. The pattern shows a more than accidental overlap with those used by Terri O`Fallon (2013) in her reframing of and expansion on Jane Loevinger`s and Susanne Cook-Greuter`s work. However, the trajectory finally revealed seems quite distinct and the application of a quadruplicate pattern – as will be shown – rather part of late stage consciousness than an individual or unique approach to structuring reality.

The article is divided in several sections. Starting with an introduction into the foundations of ego-development theory and showing how research into literature can help improve the granularity of sentence completion tests, we will go through the writings of Luhmann in a linear and chronological as well as nonlinear and comparative manner and show the dispersion of discontinuities. We look at all his books up to the 1970s and then restrict ourselves to the major ones and those which mark transitions. Intertwined with this we will show repeating patterns display themselves. They will be related to sequences in language development and hierarchies of grammar. During this process cross-references to Susanne Cook-Greuter`s and Terri O`Fallon`s work will be given to correlate the sequence with their models as best as possible as well as to other developmental psychologists and authors from social sciences or philosophy to illustrate seeming parallels. Central for this cross-referencing are Georg Wilhelm Friedrich Hegel, Sri Aurobindo, Charles Sanders Peirce, Ken Wilber and Lawrence Kohlberg. A final section will offer insights into the Tier Structure of development which stems directly from Luhmann`s work and matches that depicted by Hegel, Peirce, Aurobindo and others and how this tier structure can be correlated with Terri O`Fallons theory of stage development.

Our goals include the suggestion of heuristic principles for the grammatological analysis of text, first in an introductory fashion and then at larger granularity applied to determine the grammatical complexity of written texts. As a supplement and expansion of text scoring based upon a catalogue of examples that are matches against individual’s expression to determine a level of development as done by Cook-Greuter and Loevinger we propose grammatical and logical properties of text as more fundamental indicators of developmental complexity. This might lift grammar and logical complexity from being a palate cleanser in Ego-Development theory where it only exists as an assumed precondition for development, serves when sentence completions cannot be matched to a pre-categorized exemplar and appears as rough patterns in pre-categorized examples towards being a main ingredient for pointing towards a person developmental center of gravity in a domain general fashion or independent of different line based assessments of consciousness's maturity. Furthermore, it expands the scope of analysis from standardized sentence completion tests with a fixed number of verified items for instance towards the analysis of literary texts. It will also allow for a deeper exploration and understanding of the nature of this development by providing both a more fine-grained tool and an overarching superstructure that is at the same time a set of transcendental categories that underly a subject's linguistic operations.

This parallels the attempts of O`Fallons model, which also moves away from exemplar-based scoring to focus on the structure of language rather than its content, the specific categories of exemplars used by Loevinger and Cook-Greuter. As said, we will propose repeating patterns that underly the sequence in which developmental levels unfold as tiers of increasing grammatical complexity, and these patterns partly overlap along the explored trajectory with these used by O`Fallon. Thus, despite the many difference highlighted, our method may also productively used to refine and extend Terri O`Fallon`s model and scoring method as well as refine and extend Jane Loevinger`s and Susanne Cook-Greuter`s work.

Philosophy of Style

The article is meant as an appropriation to a more Aristotelian than Platonist view. In this orientation we pay credit to the main actor and heroic figure of this article Niklas Luhmann who can - despite several differences and expansions on ancient concepts – be considered to enact an Aristotelian metaphysical approach. By inquiring into the structure of the world, especially that of social systems, he tries to provide a better understanding of reality. Luhmann considered himself a poststructuralist thinker concerned about Autopoiesis, the self-replication and oneness of process and outcome, where nothing is solid but exist through its self-repetition and search for self-sufficiency and self-maintenance through self-narration and reentering into one's own stories and scripts of what it means to be oneself as part of society: a process that oftentimes is argued to be a rediscovery of the Aristotelian distinction of self-preservation that "comprises the complex bodily and behavioral relation of being-organized-toward-a-plan into a linguistic-semantic construct that can be objectivized as if it were a thing: namely, the entelécheia [the Form that realizes itself within a substance] or structure [that] refers, indeed, to the specific dynamic structure of self-organizing systems that preserves themselves" (Álvarez-Vázquez 2016, p. 72).

Jacques Derrida`s (1978, p. 154) statement in *Writing and Difference* that philosophy, and hence science, too, becomes easily "an abusive investigation which introduces beforehand what it seeks to find, and does violence to the physiology proper to a body of thought" seems relevant here. Of course, all we seek to find in this paper is based on the efforts of more than eight years of the author engaging in a thorough search, including avenues with mistakes and progressions within these mistakes, which lead to the living and partly unpredictable thing this article became through writing and which it is meant to become in the eyes and minds of the readers. It builds, besides other papers, especially upon a Master-Thesis about Luhmann, Hegel, Peirce and Stafford Beer (Angerer 2019). However, in being written it reveals newness, surprise and wonder within the author and is supposed to do so in the "we" it addresses and as that which and within which it writes itself as its each and anytime pre-structured and unique self-revelation. Derrida calls this play, borrowing from Husserl, the problem of structure and genesis. Or we could say of structuralism and accidentalism, of outcomes and solids or underlying ever-presents and processes and fluidity or an above floating presence of the coming and going that reality is. And "in any event, as can be seen, the necessity of this transition from the structural to the genetic is nothing less than the necessity of a break or a conversion" (Derrida 1978, p. 164) where something "differs from itself in order to reappropriate itself" (ibid. p. 166).

As Gilles Deleuze (1998) writes, there is one practical problem to each play or writing or search for understanding. The difficulty of what Aristotle called recognition, wherein an "unknown knowledge must be represented as bathing the whole scene, impregnating all the elements of the play and comprising in itself all the powers of mind and nature, but at the same time ~~the hero~~ [the oneness of the writer and reader as the oneness of that reappropriating and interpreting we] cannot represent it to ~~*himself*~~ [itself] – on the contrary […] [we must] enact it, play it and repeat it until the acute moment […] [where] repetition and representation confront one another and merge, without, however, confusing their two levels, the one reflecting itself in and being sustained by the other, the knowledge as it is represented […] [in the writing and reading] and as repeated by the […] [reader and writer] then being recognized as the same" (Deleuze 1998, p. 15). Genesis or process and structure are intermingled and the differences pointed out reveal the structure and each structure – though it might be timeless, beyond human space, before any individual consciousness and social phenomenon, even before Abraham was born but prefigured in the big bang which set in to disclose creation to itself, while, too, outside of any identity but appropriated as Brahman is appropriated in each Atman through the Ishwara and each energy fed through the aftermath and expansion of the first blink of existence – as its own differences becoming its own differentiated. It is an entering that creates a unity of the writer`s past and personality as its own all with that of the reader`s past and personality and vice versa by travelling the infinite, unbound, unpredictable but precious and with all identical discourse and mind that we all are, however approximate this all and sacred dialogue is in its particular present and pristine self-presence within a single seemingly individual and separate mind reenacting the typo in letters, words, sentences, textuality and finally an understanding.

Thus, this article moves between genesis and structure. By this we are constantly adding and taking away words and information that is reappropriating itself as that "text" and communication that it is meant to be; as distinctions and presence merged in both reader and writer: one follows the other and one within the other endlessly, eternally – drank by one moment of reading and poured out as fragment of the new whole everlastingly. There is no need to understand, though it was written with best intend of braking down the overall complexity and make it comprehensible. What is repeated can enter and what is new becomes a new possible repetition. More genetical phases are followed by more structuralist phases of this article because as Kierkegaard said, "life can only be understood backwards; but it must be lived forwards", so we write forwards and understand backwards, structure not in advance but as repetition that adds the next moment to be repeated.

The Sentence Completion Tests and Review of Literature: The Procedure

Jane Loevinger and Ruth Wessler in 1970 distinguish between four characteristics of the Ego. The Ego, like a gyroscope, is that which keeps these four functions – namely impulse control or character development, interpersonal mode, conscious preoccupation and the cognitive functioning – in balance. Impulse control and character development relate to “moral development in terms of the basis for moral behavior and the types of moral concerns” (Manners & Durkin 2001, p. 542) as well as goal-orientation. The interpersonal mode “represents the attitude toward interpersonal relationships and the other person, the understanding of relationships, and the preferred type of relationship […] [and] conscious preoccupations refer to the predominant foci of the person’s conscious thoughts and behavior, such as conformity to social rules, responsibility, and independence” (ibid. p. 542).

Cognitive functioning for Jane Loevinger (1976) is in a similar fashion as Lawrence Kohlberg (1976, p. 124f) suggested, when he said that “logical development is a necessary prerequisite for moral development, but no sufficient qualification”, that which by its increase in complexity may act as a pacer or leading variable for the lagging ego-development. It is the level of conceptual complexity a person has to structure one`s meaning making.

This level of cognitive complexity is especially valuable when it comes to text analysis. It is possible to assess the complexity level of a text and thus the maximum level of ego-development, because as Linda Dawson (2006) points out: a) the hierarchical order of abstraction and b) the logical organization of utterance change with each stage. The discourse analysis here is done to show the patterns behind the reorganization and summation of units like nouns and verbs, phrases and clauses, arising within stages, between stages and across stages.

For reasons of simplicity we here consider with Foucault (1973, p. 63) these grammars as “the preconceptual field [which] allows the emergence of the discursive regularities and constraints that have made possible the heterogeneous multiplicity of concepts, and, beyond these the profusion of the themes, beliefs, and representations with which one usually deals when one is writing the history of ideas”. The grammar or logic and level of abstractness of a certain cognitive complexity is in itself a somewhat tendentious apperception, one of the main characteristics Loevinger (1976) attributes to the ego. Thus, it is the ground for each conscious perception, interpersonal mode and character development as a network of different grammatological combinations. It defines a domain of possible objects as it works as a complexity or sophistication threshold for topics a literary or scientific text can contain and is considered causal for the fact that “a thought that arises at one level as a cliché appears in deeper, more convincing and more complex versions at a higher level” (Cook-Greuter 2010, p. 33).

The grammatological web or network thus work like different versions of a television, earlier ones can depict black and white and a highly restricted number of pixels and later ones can show 256 shades of each primary color and thus offer HDTV in 16,7 million colors. The ego in this restricted set of assumptions is basically such a TV infused with conscious perception, and the TV program is the interpersonal mode and forms of impulse control. Like a TV caries electricity as information and moving colorful images, as the medium of a certain form, we can look at ego-development as unified pattern of increasing complexity maintaining a meaningful text.

Our later analysis will span the trajectory from the Expert towards the Unitive stage in terms of Susanne Cook-Greuter, including a further segmentation of the Unitive stage or realm as we will call it, so that the scope expressed in the terminology of O`Fallon spans the whole range from 3.0 to 6.5. In the final section of this paper our reasoning will also include even later stages plus elucidate some aspects of the depicted repeating patterns by including the very earliest stages of human consciousness so that we span the whole spectrum of known stages as depicted for example by Wilber (2018) from infrared to clear light.

Methodology of Correlation with Ego-Development

Such a meaning carrying text is at least a mix of different types of grammar which collocate a) sentences which are conscious perceptions based on the modal cognitive complexity of a person`s stage (called center of gravity), thus carrying stage typical discourses about the other domains of the ego, b) those with a grammatical superstructure or underlay that expressive specifically of this particular stage (e.g. including typical grammatical variations uncommon on other stages) and certain perceptions only possible to ride on such a grammatical foundation (objects that need a certain complexity of cognition to arise e.g. see Wilber`s (2018) concept of cosmic address), but don`t exhibit the full complexity possible, and c) those which exhibit a movement to another higher or lower level of abstractness and thus drop the center of gravity`s typical grammatological web, or as Aurobindo (2005, p. 992f) puts it: they exhibit a “further cause of complexity arising from the need of integration itself; for the process [of development] is not only an ascent of the soul to a higher status, but a descent of the higher consciousness so gained to take up and transform the inferior nature”.

Or differently said, although written texts are – within the scope of this article – considered as the self-expression and self-awareness of a certain stage, they, too, should be considered as webs or networks combining different levels of abstractness. There is a so called Decalåge, as Piaget (1971) called it, the phenomenon of uneven development or horizontal displacement. The post-Piagetian developmental psychologist Kurt Fischer in unison with Aurobindo highlights and expands the idea of displacement with this web metaphor: the “local variation of activity within global order, […] the multi-directional nature of development, including forward progression and backward transitions” (Mascalo & Fischer 2010, p. 163).

Ego development is assessed via a sentence completion test, a "projective" instrument typically containing 18-36 sentence stems, such as "The thing I like about myself is...", that have to be completed. Though sentence completion tests deal with the same dynamic as “people tend to give responses at more than one level” (Cook-Greuter 2010, p. 163f), the assignment of a stage needs a certain number of responses at a stage to assign an overall score to a person – a center of gravity from where one most likely functions in one`s everyday life. Contrary to this the changed grammatical superstructure (points a) and b) from the upper list) a text has, its substance from self-awareness, can support or replace such a procedure of allocating a person a center of gravity based on a statistical rule. So, while the sentence completion test as a sort of free association task leads to answers across various stages the final score is based on only the highest handful of completions since subjects are not expected to be attempting any “best” answers. Apart of that an authored text delivers a certain overlay, points a) and b) from the above list, that besides variations, point c) from the above list, indicates a certain stage the author is writing from.

Besides that, a number of what we called marker-sentences, will show up with each new developmental level, indicating ruptures or discontinuities as well as stable plateaus. Those sentences that demonstrate the highest developmental level. They resemble typical responses triggered through sentence completion tests and thus can be used for attempts of correlation. Table 1 shows such a marker sentence, matching a response from a typical sentence completion item. Both deal with what might be irreconcilable choices at earlier stages and combines them through a “both… and… and reason” construing “conflicting alternatives as aspects of many-faceted life situations" (Hy & Loevinger 2014, S.22). He or she has a high toleration for ambiguity.

Table 1. Example for a Marker-Sentence for the Autonomous Stage of Ego-Development.[2]

Marker Sentence in Sentence Completion Form:	
A good boss… *"is able to balance company and staff priorities, whilst finding a way through the chaos to create a climate in which work is rewarding and successful".* (Miniard 2002, p. 70)	A good process… *"on the one hand creates basic conditions, which enable it, and on the other requires steps of reciprocal reinforcement of selectivity, to realize trust."* (Luhmann 2015, p. 49)
Labeled Bracketing Form:	
[$_{\text{stem}}$ A good boss] [$_{\text{choice 1}}$ is able to balance company and staff priorities,] [$_{\text{choice 2}}$ whilst finding a way through the chaos] [$_{\text{reason}}$ to create a climate in which work is rewarding and successful.]	[$_{\text{stem}}$ A good process] [$_{\text{choice 1}}$ on the one hand creates basic conditions, which enable it,] [$_{\text{choice 2}}$ and on the other requires steps of reciprocal reinforcement of selectivity,] [$_{\text{reason}}$ to realize trust.]

For working with marker sentences like in Table 1 we will a) bring them in sentence completion form if it were for the attempt of correlating it with an original completion of one of the manuals or items in use for measuring ego-development and b) use a form of labeled bracketing to indicate the relevant information or grammatical structure and point to it as a phrase of a certain category e.g. [$_{\text{choice 1}}$ …] within a paired bracket. However, we have to keep in mind that grammatological analysis has some difficulties or restrictions: as much as many modern languages have a restricted case system compared to the richness of old-Indo-European languages "we need to cover the functions covered in a particular case and we must not accept traditional labels as face value" (Blake 2001, p. 155). Much of this paper is the search for right terminology and a partial, exemplary analysis to fit in the intended purpose for this article.

Aspects of Grammar: Analyzing Overlay and Superstructure

Given the *philosophy of style* under heading 1.b and the difficulty of repetition and recognition we only open up "a single and same voice for the whole thousand-voiced multiple, a single and same Ocean for all the drops, a single clamor of Being for all beings" (Deleuze 1994, p. 304), here. We offer some specific examples on what is given more granularity and detail to within the analysis of Luhmann and point to that where each "each being, each drop and each voice has reached the state of excess – in other words, the difference which displaces and disguises them and, in turning upon its mobile cusp, causes them to return" (ibid. p. 304) as repetition that which is the being of a textuality, that which makes it cohere, fit together and become thus an organized and unified whole: the superstructure or grammatical overlay, that is hypothesized in this article as the substance or underlay of the ego.

---

[2] From Luhmann (2015, p. 49) and Miniard (2002, p. 70): Both responses fit into the scoring category "Complex psychological causation, mutual influence" as well as exhibit a "both… and… and reason" perspective where two differential ideas are connected to show how a good atmosphere within a company can arise.

For determining the complexity of the text, we explore several factors that are used to combine information and convey meaning at sentence and text levels. At the sentence and work level we will be primarily evaluate the following grammatical categories ("cases"), and their combinations, for their levels of cognitive complexity: *Nominal* (Who or What?); *Accusative* (Who or what is being or verbed?); *Dative* (To Whom or What?); *Genitive* (Whose? From what or what of?); *Ablative* (Whence? From where or whom?); *Locative* (Where or wherein?); *Instrumental* (By which means? For which ends); *Comitative* (Together with whom or what?). At the larger textual level, we will consider the complexity within forms of lexical cohesion and grammatical cohesion (conjunction, reference, ellipsis and substitution). These categories will later be used to analyze and asses both quotes from Luhmann`s life work that exemplify stages and phases within a stage and sentence completions that in terms of complexity, grammar and surface content match Luhmann`s writing in these periods, so that a picture of stages and transitions appears that is based on the Author`s understanding of the larger trajectory not only within the context of Luhmann`s writings but furthermore of developmental conceptions of ego, moral and cognition.

Within a Sentence: Subject. Predicate, Object Variations

Luhmann was German, and, since the construct of ego development as well as the procedure for its measurement were developed within the English language, we must consider certain differences between these languages relevant to our grammatical analysis. The Author of this article however is a native German and bases his understanding and analysis of Luhmann on the original texts that are as best as possible translated into the English grammatological equivalents.

What makes English sentences fit together, their coherence, is in many ways similar to German texts. Single sentences contain subjects (the actors), predicates (the acts) and objects (e.g. the goals of the actors` actions), like in "[Subject the author] [Predicate is writing] [Object an article]". However, what makes them different is the number of cases. Cases respectively are the grammatical function of a noun or pronoun. Modern English language restricts itself to three cases the nominal or subjective (he/she), oblique or objective (him/her) and possessive (his/hers). The objective case often called oblique is a nominal case that is used to create a series of subject, predicate and object. For example, in "the author is writing an article", the nominal or subjective case is the author, the "who or what" of a sentence, while the objective or oblique is the "article". In this case that which "is being or verbed". That which is being or verbed was distinct in Old English as the accusative case, and objective case as a direct object. However, Old English impoverished over the centuries and didn`t add to its case structure and thus lost this accusative and its sibling the dative case, which are both present in German language.

In the dative form of the oblique there is no direct object (the receiver of an action) within a sentence following the "author is writing", but a need for an indirect object (identifies to or for whom or what the action of the verb is performed) creating additional information regarding the direct object, "an article" and thus enhancing complexity and meaning. The sentence then would look like this "[Nominal subject: "who or what?" The author] [Predicate verb is writing] [Accusative direct object: "who or what is being or verbed?" an article] [Dative indirect object: "for whom or what is something being or verbed?" for a journal]" – literally the German dative in English would look like this "[Nominal subject and predicate verb the author is writing] [Indirect dative object a journal] [Direct accusative object an article]". As we can see the sentence was enhanced by some sort of possessor or beneficiary "who is receiving" or "for whom" the direct object is generated. By this the verb or predicate is followed by more than one object, it becomes di-transitive – "di" meaning "with two" and "transitive" meaning "goals" or that which is "aimed at or towards": hence there are now "two goals or aims" instead of one. Like in developmental psychology the accusative object here is necessary but not sufficient for the later. A dative object can only occur after or connected to an accusative, that`s why this seriality is oftentimes called a natural and universal hierarchy in linguistics; more universal languages without accusative don`t show a dative either, all languages with dative show a form of accusative (Blake 2001). However, like in the example above, the dative structure, the indirect object, can often be indistinguishable from an accusative. Especially if the indirect object follows a direction it can demand a second accusative object. This leads to an accusative of "place to which" or a causative e.g. "[Nominal subject and predicate verb the author asked] [Indirect accusative object the journal] [Direct accusative object for a publication]. So, the move from accusative to dative is more a gradient than a leap.

The paucity of case makes modern English a so-called analytic language in contrast to the synthetic German and most other European tongues. We don`t want to lose ourselves in detail here but the basic difference is that English uses strategies like prepositions, verbal voice, word order, and possessive 's for its textuality – intentions, acceptability, informativity, contextuality, intertextuality, coherence and cohesion – whereas Germans use inflection or agglutination to express syntactic relationships and the forms these relationships transport (Haspelmath & Michaelis 2015). Inflection means to increase the length of a word and changing its form by use of morphemes. A root is enhanced and thus a grammatical property assigned.

Since these distinctions are as all distinctions in this paper used in a relative rather than an absolute sense, we can show this with the English example from above. When inflected one can substitute the "author writes the article" by the more passive form of "the article is written by the author", the root "write" was enhanced and inflected by dropping an "e" and adding a morpheme, the "ten".

Agglutination means the creation of compound-words like the German "Zeitgeist" would in English rather be created by a possessive or genitive structure "the spirit of our time" or "a time`s spirit". Some languages even move into being polysynthetic as do some German author`s, where whole sentences are arbitrated by one word like the Heideggerian "being-in-the-world" which fuses the quadruplicity of subject, object, consciousness, and world thus expressing the deep relationship which he so painfully missed in his philosophical predecessors like Immanuel Kant: their ability to have the "complete grasp of the structure of care which includes the phenomenon of selfhood as being-in-the-world" (Heidegger 1969, p. 324).

Still, German, too, has an impoverished case system compared to other Indo-European languages (Quiles & Menchero 2017). The grammatical hierarchies of languages with all nominative, accusative object, dative object and possessive cases often include so-called modifications. Cases which center around changing the predicate verb of a sentence for example through a) adverbial or b) adjectival intensifiers functioning as c) complex prepositions modifying the relationship between nouns and pronouns (I, you, he/she/it etc.). Furthermore, these cases are changing predicates into nouns as categories of place, time or means to an end.

An a) adverb is something that is "ad-verbal" hence for support of a "verb", a Latin form of "at-the-verb". They answer questions of manner of "how" (angrily, happily, easily etc.), place or "where" (near, there, here etc.), time or "when" (soon, now, then etc.) and frequency or "how often" (daily, sometimes, never etc.). An b) adjective`s main syntactic role is to modify nouns and noun phrase through adding descriptive and qualitative (large, nice, cute etc.), quantitative (first, second, third etc.) or demonstrative (this, that, these etc.) descriptors. Complex prepositions c) in contrast to simple prepositions (by, at, on etc.) can be adverbials and adjectives in form of double prepositions (into, out of, from within etc.), compound prepositions (in addition to, on behalf of, in the middle of etc.) as well as participle prepositions (considering, during, concerning etc.) and phrase prepositions (on time, at home, before class etc.). They, too, help modification towards the dative form of objective cases while enriching the complexity and meaning of a sentence through additional information. This additional information refers to:

a) the *ablative*, the "direction away from of a dative object" e.g. in "[Nominative: "who or what?" the author] [Predicate verb moves] [Accusative object: "Who or what is being or verbed?" his laptop]" [Ablative modification as adverbial of place: "where from?" away from] [Dative object: "From whom or what" his lap]

b) the *locative*, the "place of dative object" or the place "from where" or "towards which" an object comes or is moved e.g. in "[Nominative: "who or what?" the author] [Predicate verb moves] [Accusative object: "Who or what is being or verbed?" his laptop] [Ablative modification: "where from?" from his lap] [Locative modifier as adverbial of place: "Whereto?" towards] [Dative object: "Towards whom or what" the table]";

c) the *instrumental*, the means "by which" or the "in order to" e.g. in "[Nominative: "who or what?" the author] [Predicate verb moves] [Accusative object: "Who or what is being or verbed?" his laptop] [Ablative modification: "where from?" from his lap] [Locative modifier as adverbial of place: "Whereto?" towards] [Dative object: "Towards whom or what" the table] [Instrumental modifier as descriptive adjective modifying next noun phrase: "Whereto?" in order to] [Noun phrase predicate and object get up for a break]";

d) the *comitative*, the one "with whom or what" one shares or intends "to be with" e.g. in the instrumental, the means "by which" or the "in order to" e.g. in "[Nominative: "who or what?" the author] [Predicate verb moves] [Accusative object: "Who or what is being or verbed?" his laptop] [Ablative modification: "where from?" from his lap] [Locative modifier as adverbial of place: "Whereto?" towards] [Dative object: "Towards whom or what" the table] [Instrumental modifier as descriptive adjective modifying next noun phrase: "Whereto?" in order to] [Noun phrase predicate and object get up for a break] [Comitative modifier as phrase preposition "with whom or what" with a friend and a cup of tea and cookies]";

There are many sub-cases and structures of these modifications. And as we will see later, they all help to increase complexity in a relatively fixed and natural order. Now there are no longer two aims or di-transitive expressions of the predicate verb but so called multi-transitive verbs followed by multiple nouns and noun-phrases enhance the informational value of a sentence.

Following two of the basic laws of narration, that of redundancy and variation as well as that of diversification (Koschorke 2012), we now, after having created closeness to the intricate structure sentences can comprise, go into a larger variation of this which for example concern different cause structures; it is now time to look at the theoretical foundation of how different sentences are connected into a whole the author is writing. Afterwards, we dive back into repetitions increasing the resolution of our grammatical television screen as we further diversify and differentiate "into what holds the writing together at its core" by analyzing Luhmann`s life work. Table 2 sums up what was said in this section and ads a bit to it.

Table 2. Some of the depicted grammars, their workings and abilities to convey meaning.

English Name:	**Subjective Case**		**Objective or Oblique Case**			
		Saxon Genitive with Suffix			Prepositional Genitive construction	
Gradient	Rather Nominal (Denominating/Objective) →					
					← Rather Possessive (Correlating/Subjective)	
General Name:	Nominative	Nominal or Accusative Possessives	Accusative	Dative	Genitives e.g. of - Composition - Participation - Origin - Reference - Description	Modifications e.g. - Ablative - Locative - Instrumental - Comitative
Valency:	Intransitive		Transitive	Ditransitive		Multitransitive
What happens?	Makes the subject and words after the verb the same.	Makes a Nominative by modifying a noun through another noun.	Makes an object for the subject through a direct verb.	Makes an indirect verb by adding a beneficiary of the object.	Makes possessive relations by modifying a noun through a noun with preposition.	Makes complex means-ends relations by modifying the predicate verb.
Meaning Conveyed:	Enables a naming of the Subject and seeing subjects as their own purpose.	Creates a compound subject or univariate relation.	Indicates action and direction or univariate relation.	Shows a beneficiary or emphasizes specifically thus creating reciprocal relations.	Makes e.g. possession, composition and references possible	Enables directional and means ends schemes that unify subject and object.

Within a Text: What holds Together Textuality

“’New meaning’ is largely created out of ‘old meaning’” (Koschorke 2012, p. 163) and thus a text is based on a space or field of “meaningful Integration” (ibid. p. 162) of old into new. It is an openness of semantization and de-semantization and the reappropriation and extension of what was said earlier. M. A. K. Halliday (2004) in his *Introduction to functional Grammar* points out the main difference of analyzing textuality in opposition to the analysis of a single sentence. Here “the organization […] is semantic rather than formal, and much looser than that of grammatical units” (Halliday 2004, p. 524). Far beyond being only structural it is genetic, too, one has “to be able to think of text dynamically, as an ongoing process of meaning” (ibid. p. 254). For him the dilemma of structure and genesis is solved by moving into distance and making the living, dynamic thing a system. Such a system than can be seen as compartmentalized into four major types of cohesion which interlace sentences within a text: three of them work through grammar and one through lexical means, through repetition and other forms of reappropriation to earlier words and their meaning (Korte, Müller & Schmied 1997).

1. Grammatical Cohesion:
    a. Conjunction: This means that clauses are connected through conjunctions, whereby different types of linking words exist. Additive ones (e.g. and), causal (e.g. therefore), temporal (e.g. afterwards) and adversative (e.g. even though) work together.

    b. Reference: This means that language units cannot be interpreted as separate rather as interconnected, they reference each other. This can happen in personal form through personal pronouns (e.g. they), possessive determiners (e.g. my) and possessive pronouns (e.g. mine). But, too, as demonstrative through articles (e.g. the), demonstrative pronouns (e.g. this) or adverbs (e.g. then) or comparative references. Comparative references again can be pointing to sameness through adverbs and adjectives (e.g. same), similarity (e.g. similar) or difference (e.g. otherwise).

    c. Ellipsis and substitution: Here ellipsis means to elide or drop structural elements (e.g. “I write, and you write” becomes “I and you write”). Ellipsis eventually can culminate in substitution where semantic short forms replace larger elements (e.g. “I write, and you write” becomes “I write, and you, too”).

2. Lexical cohesion: This means that “lexis is organized into a network of lexical relations” (Halliday 2004, p. 570). Differently said each word or phrase within a language can in relation to a known cultural lexical background be substituted by other words. A “writer” has lexical cohesion with “author” and “author” with “text”, while “text” again points to “writing” and the “writer”: languages have synonyms, antonyms, hyponyms, hypernyms and meronyms.

What lexical cohesion is varies strongly with culture and time as Michelle Foucault (2005) shows in *the Origin of Things*. It is based on epistemes which for example rely on a certain amount of similitudes in which “signs themselves […] [are] no more than a play of resemblances, and they refer back to the infinite and necessarily uncompleted task of knowing what is similar” (Foucault 2005, p. 46). And thus, discourse works in such a cultural epoch as something that “by trying to approximate to it, by attempting to say things about it that are similar to it, […] [brings] into existence the infinity of adjacent and similar fidelities of interpretation” (ibid. p. 46). And these epistemes are here hypothesized to not only change with variations in thought through new insights and life-conditions but with each stage of human development, too.

As Jürgen Habermas (1979) puts it in the *Reconstruction of Historical Materialism,* cultures do not per se belong to a stage: the complexity of cultures is a multidimensional concept it can be judged “in respect towards size, interdependence and variability, with respect to achievements of generalization, integration and respecification” (Habermas 1979, p. 141) as well as the increase in complexity of single individuals in a culture not necessarily leads to an overall increase in complexity rather can create “evolutionary dead ends” (ibid. p. 141). And since cultures don`t share solid boundaries as organisms do or as a person does “the relationship between complexity and self-maintenance becomes problematic" (ibid. p. 142) since larger numbers of people have to adopt to new forms of discourse and inhabit new epistemes and according perceptions and behaviors to sustain what lexico-grammar transports within the operational realm. However, since a) deterioration in individual developmental levels can happen through personal practical and moral life dilemma and b) these quandaries and their solutions can "gain entrance into the interpretative system of the society through exemplary learning processes" (ibid. p. 161). The evolutionary challenges perceived and spread by these individuals and the initiated learning processes can then c) make an adaptative shift of the whole society necessary and finally d) "the introduction of a new principle of organization [e.g. a new episteme] means the establishment of a new level of social integration […] [for which] the learning processes of moral-practical consciousness functions as pacemakers" (ibid. p. 160). From our point of view each culture thus establishes a certain grammatical web that e.g. impoverishes like modern English when certain stages of development – as we will see, these who are closer to the end of a tier – which have enacted a society with multiple modes of grammar disappear. Thus, impoverished grammar might, too, inhibit the overall capacity of a society to evolve since more complex modes of discourse are inhibited by social convention and thus might be part of solidifying autopoietically processes. Or as Luhmann (2018a, p. 538) would say systems "create observations that confirm and condensate certain semantics by which meaning valuable enough to be preserved gets identified, held on, remembered or left for oblivescence".

Between this layer of cultural discourse and that of widely universal and cross-cultural grammars, which only vary in sophistication and scope as numbers of grammatical operations and functions, a third element is essential to hold together textuality in its core. The theme to rhema shifts that bind together the surface level grammar and the deep embodied and immanent structural concepts, the lexis of discourses (Ongstad 2007). Normally "the theme is the element which serves as the point of departure of the message; it is that which locates and orients the clause within its context. The remainder of the message, the part in which the theme is developed, is called […] the rhema" (Halliday 2004, p. 64). Mostly the theme is recognizable as it introduces the sentence as in "[Theme: "who or what is it about?" the author] [Rhema: "what does the author do, what is important about him?" writes the article]".

However, when it comes to two or more sentences what is additionally of interest is the question for new and for already given information. The interlacing of sentences, as shown, works through lexical cohesion, through the reappropriation of the earlier and the connection or contrast to something new. Here we can redefine theme as that which creates the lexical cohesion as adopting the given meaning of an earlier sentence, and the rhema as that part adding new content, information and meaning. Then the theme is no longer necessarily the introduction to a sentence, though that`s the common case, but can show up as any part of the sentence relating back to something earlier and given: to that which is explored, the thematic content of a passage or text – e.g. as in ["Theme the author] [Rhema writes an article.] [Theme: as given information and lexical coherence The article] [Rhema: as new information is about language]" compared to ["Theme the author] [Rhema writes an article.] [Rhema: as new information It was language] [Theme: as given information and lexical coherence the article] [Rhema: as new information dealt with]".

Overall picture of Grammatical Analysis

As depicted grammar and lexis, the universal and the culturally conditioned interact within textuality. In the middle so to say is the process that a text is: a dynamic flow of theme into rhema, given into newness, repetition into difference and reappropriation into recognition. The process is depicted in Figure 1.

The Discontinuities in Luhmann`s Writings

The core of this paper to crystalize a developmental progression from the conceptual complexity and content of Luhmann's writings that simultaneously is used to exemplarily carve out, illustrate and further develop a domain general scheme for the developmental analysis of text. This will contribute to a general understanding of Luhmann's ideas, and their progression while it both supports and challenges the usefulness of different tools for measuring stage-like development thus opening a window for a broadened discourse that includes the different conceptions of Ego-Development, models of hierarchical complexity, moral development and spiritual as well as philosophical conceptions of growing and waking up as a human being. We will focus particularly on the progression of ideas specifying the relationship between a system and its environment, and how systems are created and self-maintained. The first half of this endeavor will almost solely focus on Luhmann and some of the main ideas of his earlier writings including the operationalization of mistakes and trust in formal organizations. Towards the end of the article we put emphasis on a rich comparison with other late stage thinkers to show not only grammar but some general traits or surface structures people at these stages seem to embody. This, too, is accompanied by differentiating two basic types of looking at the world: an inside, more Aristotelian, and an outside, more Platonic, view – both terms will be clarified later in section *3.b.iv Preliminary Contemplations on Tier Patterns*.

One of the main ingredients of Luhmann`s two major works the 1984 *Social Systems* and the 1997 *Theory of Society* is the idea of differences between systems and environment. These differences start with the “invention of negation and with the through negation enabled Yes/No coding” (Luhmann 2018a, p. 459). The coding allows one to accept communicative offerings and thus the variation, selection and re-stabilization of system-boundaries, “a unity in difference to an environment” (Luhmann 2002, p. 412). However, for late Luhmann both, yes and no, are intriguingly connected – the variation or the no is, too, a selection, a yes, towards something more or less contrary or to nothingness. In his posthumously published book *Organization and Decision* (2000), he writes besides the duality created by a coding about the possibilities of pointing to an "either… or", a "both… and", as well as seeing a "both… and… and the relationship of both sides of this both… and".

Coding means that we create a dichotomy, one that allows difference and thus divergence and novelty. Derrida (1999, pp. 44f) calls "the praxis of language or of coding as a play of forms without specified and unchangeable substance, […] a play of traces"; traces which, so Luhmann, represent systems as relatively stable and fixed as well as irritable modes of communication. The coding allows to test for functional fit and selection, variation and integration or negation. When a coding arises, for example as the difference of formal and informal organization, the logically sound first step is the recognition that one side of the coding is not the other ($A|B$) or both are the same, or rather: one merely reduced to the other ($A = B$). From this starting point Luhmann unfolds a trajectory in *Organization and Decision*: after the first dichotomy comes a second where an organization is always either formal or informal ($A \veebar B$) and the organizational procedures sort events into these categories, or it arises as an univariate relation which easily leads to the subordination of the one under the other, where either the formal or informal is superior or earlier to its opposite ($A \rightarrow B$). For Foucault this was the main mechanisms of 16th century discourse "it was the relation and interplay of subordinations between describing, articulating into distinctive features, characterizing, and classifying; it was the reciprocal position of particular observations and general principles; it was the system of dependence between what one learnt, what one saw, what one deduced, what one accepted as probable, and what one postulated [as truth]" (Foucault 1972, p. 57). As a third after the second where "opposites had been formulated, where depending on circumstances one or the other side appeared as worthy of promotion […] [, where] groups took on the appearance of formating cliques" (Luhmann 2000, pp. 303f) comes the recognition that there can be "as well formal as informal organization" (ibid. p. 303), a "both… and" ($A \wedge B$) approach to looking at ones system. This, too, can be the recognition of the inherent interactions, interconnections and thus the necessity of integration of both sides ($A \leftrightarrow B$) beyond univariate relations; as a fourth mode an organizational system can be "depicted as basically bi-resilience" (ibid. p. 304) as unity that is "autopoietic and the construction of the system with one operation" (ibid. p. 304) an operation which is basically both sides of the coding and their relationship to each other, a oneness ($A \cap B$) that at the same time maintains itself in this relationship through being both: what it is and what it is not ($A = \neg A$) where both sides are equally important and can only exist in being co-subordinated to each other or in a permanent shift to reference both.

Coding thus allows a trajectory of unification of its own opposites which at the first sight mirror the steps of the "polar opposite pattern" that Terri O`Fallon (2010, p. 20) points to in her thesis *The Evolution of the Human Soul*: "awareness of only one side of a pole; awareness of polar opposites and choosing either one side or the other (either/or; neither/nor; awareness of and choosing both sides of the polar opposites (both/and); interpenetrating both sides of polar opposites: the passive, active, reciprocal and interpenetrative phases of understanding.

However, Luhmann as a student of Talcott Parsons does not identify these grammars with passive, active, reciprocal and interpenetrative, rather sees them as his versions of Parsons`s (1991) adaptation, goal-orientation, integration or interpenetration and the maintenance of patterns. Thus O`Fallon`s fourth Term would in this scheme just be the third, while reciprocation as we will see later would be just a minor part of this third step in the overall quadruplicity. Adaptation between the environment and the social system is basically a function of communication as evolution "the basal process of social systems, which reproduce the elements, out of which they consist" (Luhmann 2012, p. 191). Activity according to Parsons (1991, p. 4) comes into play through goals, where an actor "may actively attempt to control the situation in conformity with his wishes or interests". For Luhmann (2012) goal-orientation or attainment and activity is based on the realization of a system/environment difference in reality where the system can be either a person as a consciousness-system in difference to other persons or any system as coherence of communications distinguishing itself from other modes of coherent communications. However, this "either/or is no absolute, it is true only relative to an individual system, but in the same way objective" (ibid. p. 244). It is the correlate of observation, which introduces such a distinction in so far as "they pursue a higher ordinal-interest" (ibid. p. 246), hence certain goals. The difference between system and environment asks for mechanisms of integration or interpenetration. Here Luhmann (2018b) is quite consistent with Parsons`s (1991, p. 10) idea of "a kind of 'compromise' between the 'strains to consistency' of […] personality, social and cultural components respectively, in such a way that no one of them closely approaches 'perfect' integration". Distinctively, Luhmann who rather looks at communication than at personality as well as social and cultural components, considers integration as a structural drift of "integration and disintegration from instant to instant […] as the countless eventful operative couplings, which cause a permanent establishing and dissolution of system-contexts" (Luhmann 2018b, p. 605f). In *Social Systems* Luhmann (2012, p. 290) speaks here of interpenetration "as the intersystem-relationship between systems, which reciprocally belong to environment for one another […] [and] reciprocally enable each other by yielding their pre-constituted private-complexity into the respectively other" (ibid. p. 290).

The fourth on the trajectory, Parsons`s (1991, p. 13) idea of latent pattern maintenance, "the formulation of mechanisms which 'account for' the functioning of social systems, for the maintenance or breakdown of given structural patterns, for a typical process of transition from one structural pattern to another" included for Luhmann (2012) to much of the traditional ideas within the wholistic or neo-platonic mysticism of Hegel, the idea of a real unity within being. To make the grade of his post-structuralist roots he therefore introduced a new fourth idea: self-description as self-reproduction, which sustains a system`s structure as process by thematizing itself. A process that is the unity of difference and repetition, a system as its own "autopoiesis": how communication creates communication and creates structure within a temporal living out as repetition of certain operations and the permanent reappropriation of the old status, or the reaction and constitution of new operations from old ones if new irritating events occur.

While for Luhmann (2017a) in his 1975 book *Systems-theory of Society* this self-thematization is "completely immanent" to social systems and reflects the idea of what is consciousness in conscious systems or persons, Luhmann`s later writings emphasize the necessity "of a change in form of self-description […] [which] lies within the transition from a first order observation towards a second order observation" (Luhmann 2018b, p. 1140f). The "use of self-reference with discriminatory function" (Luhmann 2017a, p. 916), which is as a self-reassurance that is completely immanent to the system a "constitutional-process which thematizes systems-identity" (ibid. p. 920f) and controls e.g. adaptation, the source of adaptive change of system and/or environment, turns first into self-observation: a distinct operation as the "handling of distinctions. […] The introduction of the system/environment difference into the system which constitutes itself with the help of this distinction; and at the same time as an operative moment of the autopoiesis, because within the reproduction of elements it has to be guaranteed that they are reproduced as elements of the system and not as something else" (Luhmann 2012, p. 63). Observation becomes the coordinative function of self-referential-closed systems with openness towards their environment – they are holding all earlier functions of communication, difference, integration and self-thematization together. With an overflow of communicative possibilities Luhmann states the necessity of a level of second order observations, which means both a) that the differences and distinctions, the observations and descriptions, are created by differences and distinctions, the observations and descriptions themselves and thus have to describe themselves in their descriptions – the observer "must apprehend its content as a self-descriptive content" (Luhmann 2018a, p. 16) – b) and to take responsibility and make a choice "from which system it views others as environment […] and that descriptions are poly-contextual: each describer in his descriptions is describing differently" (Luhmann 2018b, p. 1141).

Luhmann himself distances himself from a hierarchical developmental perspective when he negates the idea that second order observation is sourced by a later, higher or "'better' observer – but rather by just another observer" (ibid. p. 1142). Nevertheless, the structure of his three greatest masterpieces the 1975 *Systemstheory of Society*, the 1984 *Social Systems* and the 1997 *Society of Society* show three phases of his orientations towards how and by which operations systems are created, a) by themselves through immanent self-reflection, b) which is framed later on as an observer coordinating four functions of systems (which were named adaptation, goal-orientation, integration and latent pattern maintenance by Parsons) or c) through pointing to observations of observations and a second order observer, which is able to decide for certain descriptions of society, by finally including that what is doing the describing into the descriptions and by being aware of alternative descriptions and describers in an autological fashion.

We now take this trisection of Luhmann`s life for our course through his work and direct our focus especially on how two sides of a coding are related to each other, especially systems and their environment. The passages from Luhmann`s books where chosen by looking into the index of keywords and basically choosing "difference between system and environment" or "differentiation". Too, for the final assignment of a books to certain phases, the first and last chapters were compared for eventual shifts in grammar and stage especially as some of the Luhmann`s later books have been written in parallel over the course of seven years or so. Additionally, the author has read approximately half of the 27 compared books and articles in completion and the depicted trajectory was researched and recognized within several authors life works.

Our hypotheses here as depicted in Table 3: Terri O`Fallon's polar opposite pattern depicts only the first of the three phases Parsons and Luhmann identified, thus subdividing the integrative phase into reciprocal and interpenetrative, i.e. integrated, substages. The distinct functions of the social system and the different tier changes are visible both in sentence completions and Luhmann`s as well as other author`s writings and pointed to throughout the rest of this article. Additionally, Table 3 shows the trajectory we genetically investigate within the next three subsections before a more structural section synthesizes the pointed-out discoveries into a larger picture. A more comprehensive outlook of the stage trajectory in comparison is given in Figure 6 in the end of the article.

Table 3. Investigated trajectory of the next section and mentioned models in approximate correlation.

Luhmann		**O`Fallon**		**Hy/Loevinger & Cook-Greuter**			**Mascolo & Fischer**	**Kohlberg & Habermas**

The Early Works of Luhmann: From the Conscientious 1960s to the Construct-Aware 1970s

1964 and 1966

Luhmann`s second book is called *Functions and Consequences of formal Organization*. It deals with the formalization of organizational systems as an elementary process of human contact and relationship (Luhmann 1964). It shows the necessity and possibilities of formal and informal strategies of establishing social systems and the resultant problems of possibilities for increasing complexity.

Differentiation here is a means of "keeping certain states and trajectories invariant in opposition to a changing environment, which can be improved and expanded, by subdividing a system" (ibid. p. 73). Differentiation takes the leading role and integration is subordinate to differentiation, "it basically serves the goal of boundary-retention" (ibid. p. 79). Too, it has to be mentioned that integration is synonymously used with adaptation. Some years later in his dissertation about *Right and Automation in public Administration* this conflation of terminology still exists, however than, he states conversely to the subordinationistic perspective that for sustaining a system in a highly complex and volatile environment two strategies are equally necessary: the first, namely adaptation or integration "as the institutionalization of common values and forms of cooperation between system and environment relevant to them" (Luhmann 1966a, p. 23) and "as alternative to this 'external' mode, there is an 'internal' mode to reduce complexity, namely through internal complexification of the system"(ibid. p. 23), hence differentiation. The increase of inner variability leads to an ability to chunk down what comes from the outside of a system.

In the same way one can see the focus on sustaining boundaries in Luhmann 1964 compared to 1966, in observation of the concept of mistake. In his book about formal organization he writes about the frustration of expectations and the assignment of guilt and causality: the lead motive is “the relation of the salient, disappointing experience to solid and proofed experiential structures, […] which cannot question the rightfulness of expecting the right. […] The explication of frustration and reaction of disappointment in open action both have the symbolical meaning of a demonstration of a violated norm” (Luhmann 1964, p. 253f). The fact of a mistake “as a sort of natural catastrophe, which invades the system from outside” (Luhmann 1966a, p. 76) falls away out of the conceptual space. The mistake is simply “an interpretation of events […], already an internal category of the preparation of experience” (ibid. p. 76). Additionally, as it cannot be localized internal either, it “perforates the internal/external differentiation. It further fuses the differentiation of structure and process, as it can only show up in a working process, but as a disruption of its original structure” (ibid. p. 75).

Luhmann in 1964 has in his dealing with the concept of mistake and frustration a grammatical overlay that is both strongly relativistic in an “either… or” fashion and polarizing. The relativistic side shows up e.g. in sentences like “[relativity notion depending on] [sources of dependencies the whole situation of the system and its overall attractivity] [either… or notion it can be better ruled by threat of punishment or positive incentives]” (Luhmann 1964, p. 255), while the polarizing aspects can be recognized in “[neglected idea 1 the formalisms of expectation and sanctions understands itself not through itself,] [polarization it rather] [prioritized idea 2 has to be explicated in its specific function and the resulting follow up problems]” (ibid. p. 254). Besides that, as shown two completely opposite points of view can be coordinated but not in the “both… and” fashion of his 1966 writing rather as subordination of one side within two ambiguous perspectives. But not only can one see the differentiation through this grammatical underlay of polarizing and subordinating but the reflection of the limitation to one`s own capacities – “specifically with increasing differentiation it is no longer possible […] to master the system with the normal, natural-concrete perceptional and emotional powers of humans” (ibid. p. 81).

This sentence echoes the overall structure of Luhmann`s style in *Functions and Consequences of formal Organization* from 1964: sentences are highly complex and use many forms of interlacing across sentences or combinations of independent clauses into one sentence. Contrary to this *Right and Automation* in 1966 is largely based on short nominal sentences, longer sentences are linear and as we will see can be divided in two classes. Additionally, there is a change from “this means” to “that is”, one can as later shown, explain from nominal single persons` points of view in contrast to the comparative and relative structure within later phases of a grammatical cycle.

Grammar from 1964 to 1968: Achiever vs. Pluralist

In 1968 Luhmann’s book *Trust: A Mechanism for reducing Complexity* was published. Trust didn`t play a large role in 1966. However, there is one passage of interest. It deals with the protection of trust and shows the simplicity of the early “both… and” structure. Luhmann (1966a, p. 90f) writes that “each system needs ‘latent’ functions and structures to stabilize itself; they cannot be illumined without forcing the system to change its identity and relocate the shadow of latency. Relocate it to the realm of latency of the public administration, to the function of its end-ideology and the function of law. One would overstrain the decision capacity of the state-administration, if one wanted, that its constituting moment: the right, in the sense of a limited public interest to justicement, is used as an available value besides others. Is it doing so and believes thereon, than it uses formulas like ‘public interest’, ‘interest in legal certainty’, ‘equality’, ‘justice’ and so forth as superficial empty formulas and retains its own essence in the unconscious. The over abstraction of these terms serves simultaneously to secure the latency of some of the motives and decision-making basis.”

This passage shows that some basic characteristics like sentences though using nominal, accusative and possessive grammar, these cases can be identified grammatically by asking for a nominative, the case of the subject of a sentence and predicate nominative which can be a transitive verb, too, and which is revealed by the question: "Who or what?" One does not make a huge mistake when asking What between some of the sentences "[Nominal: what? One would [transitive verb 1 overstrain] [nominal phrase the decision capacity of the state administration,] [if] [who or what? one] [transitive verb 2 wanted [that clause that its constituting moment is used as] [who or what? an available value besides others]". The overarching grammatical pattern is that of a definition pointing to feedback loops creating an implicit "both… and" and dealing with effects of a "both… and" perspective. As Luhmann precedes he shows how the "public interest" as additional value to protect trust leads to "more attention for the system-principle of constitutional administration, which basically is less able to serve public interest" (ibid. p. 91). Differently said: non-linear effects are made visible.

Trust in 1964 cannot be hailed by asking the nominal "what?", rather a location as a "wherein" is most significant when "failproof, but therefore partly feigned procedures of consensus-creation [like trust] can only be institutionalized within a certain social circle, which is obliged for acknowledgment of the result" (Luhmann 1964, p. 71). It can be best identified by the set of cases not dealt with in modern English. The cases which all mark the same syntactic relation, that of optional modifiers to the main verb we introduce in the paragraph

Within a Sentence: Subject. Predicate, Object Variations.

We basically know these cases from the Latin, Russian or old Indo-Germanic languages and in this case belong to the branch of ablatives, locatives, instrumentals and comitatives. The locative is the case which locates something either physically or temporally and can be identified by the question: "Where or wherein? When?" e.g. as in "[When or wherein can trust be institutionalized? Within a certain social circle, which is obliged for acknowledgment of the result]". Further in 1964 "contracts, if one or many have to input without immediate satisfaction, […] a contact has to be carried by trust" (ibid. p. 72). There the main case is another modifier to the verb "[by which means or how can a contact be carried out? by trust]" – creating an adverbial phrase using the preposition.

In the 1968 *Trust* the feeling of trust, too "enables relatively safe expecting and therefore, too, an absorption of residual risks, but is itself neither favorable nor unfavorable expectation, but condition for the possibility of both. Trust is the precondition for trust as for mistrust, so to say for each kind of engaging oneself into a certain type of attitude towards the future" (Luhmann 2014, p. 25). What is more obvious here, than in the so far quoted passages from 1966, is the "both… and" condition of the grammar. While in the earlier writing "both… and" seems to be the structure of what is implicit as the basic awareness or way of conscious preoccupation, it now is pointed out clearly. Furthermore, it is now related to a direct or accusative object. This object is subjected to the "both… and" agent – "[ergative agent trust] [who or what is being or verbed? enables relatively safe expecting and therefore, too, an absorption of residual risks,] ["both… and" agent but is itself neither favorable nor unfavorable expectation,] [who or what "both…and" is being or verbed? but condition for the possibility of both]". At the same time accusative forms we only knew from Latin in concrete form like the accusative of "place to which" show up: [subject complement or reflexive Trust is the precondition] [who or what is being or verbed? for trust as for mistrust, so to say] [who or what is being or verbed? for each kind of engaging oneself] [who or what is the place that is being or verbed? into a certain type of attitude towards the future]".

This more complex grammar shows up already on the last pages of the 1966 *Right and Automation in the public Administration*. While within the more polar or paradoxical sentences of 1964, like “fictions have to be depicted as realities, but may not be treated as realities” (Luhmann 1964 p. 278), one has instrumental notions recognized by the question of “How”, forming an instrumental case of causers and thus showing positive directions for action, the accusative and thus agentic sentences of 1966 show a critical stance to agentic practices and means, goal-orientation and causes: “[who or what as means or practices? If goal-orientation on the one side and justice-orientation on the other have ever provided] [who or what is being verbed as criticism? the best alternative for reducing complexity, has never been proven; neither, [instrumental as what and “both… and”? how both methods relate to each other and how they can be boxed inside each other]” (Luhmann 1966a, p. 142).

If we want to explain it solely on the basis of grammar as what sustains and is conscious perception as both a spark of information riding on it and the self-recognition of this grammatical web through the attended spark by selective apperception, one can say that it could arise through a third grammatical operation similarly as models of hierarchical complexity assume that growth and development through abstract stages is signified first by being able to think “in terms of a single, intangible, generalized abstract concept […] before teens begin to coordinate two single abstract sets into an abstract mapping” (Mascalo & Fischer 2010, p. 158) and finally systems thinkers are able after creating relations between multiple abstractions “to coordinate two abstract systems level conceptions into a system of abstract systems” (ibid. p. 159) through a third, a single principle.

The standard structure of the 1964 writing are sentences built up out of three segments: the first is either quite short, sometimes just a connective, and builds a linking to the earlier sentence, it is referential, switches from rhema to theme, from the unknown to the known – or a more elaborated version of the rhema –, and substitutes through a) short phrases, followed by two sentences which are causally connected, polarized or subordinated or b) the earlier theme is further elaborated and differentiated within a theme while the third part offers a new rhema. The third part thus is oftentimes built into the sentence by a connective which expresses an opposing or limiting statement. Follow up sentences connect through complex mechanisms of interlacing as said, they both integrate and further evaluate the earlier, they are co-subordinated and switch references fluidly.

For example, when it comes to functional differentiation “[rhema 1 subsystems can grant the invariability of their own boundaries within the overall system.] [theme 1 as new information about rhema first part Certain states, action-sequences, event-trajectories are guaranteed,] [theme 1 second part and others ruled out,] [rhema 2 limiting statement without other system members having to bother themselves.] [theme 2 Each subsystem can follow its own purpose,] [rhema 3 limiting statement without attending to it recklessly or exclusively,] [rhema 3 part two and by this stay highly indifferent against that what others are doing]” (Luhmann 1964, p. 76f). This structure matches the more complex achiever responses in the sentence completion test, which, too show instrumental and locative grammar and modifications as can be seen here: “[People who step out of line at work…] [rhema 1 with instrumental of cause often believe they have valid reasons to step out of line.] [theme 1 as new information They should be listened to [rhema 2 limiting condition however, boundaries must be set and communicated] [rhema 2 part two and consequences must be made known of behavior ignorance]” (Zavarella 2009, p. 54).

In 1966 not only the way differential sentences are connected changes: there is not as much a shift from rhema to theme, rather each sentence is a rhema itself and the connection happens in an equation-like or homonymic style through substitution and pronominal reference. So, differentiation is defined as something that is beneficiary in a "both… and" manner, for example "[rhema 1 the society becomes more elastic, adaptive and simultaneously sustaining.] [pronominal reference as equation It can] [rhema 2 in limited doses react problem-specific,] [rhema 2 equation with new information hence fast]" (Luhmann 1966a, p. 136). There arises a new net which can hold two perspectives at the same time, through this third operation. As we can see in the sentences from 1964, there is one action-oriented part and one that is passive in the sense of describing adaptive behavior – "[active part Certain states, action-sequences, event-trajectories are guaranteed, and others ruled out,] [passive part without other system members having to bother themselves]". – or shows adaptive processes of two co-subordinated parts – "[theme One can only speak of a subsystem of an overarching system,] [rhema 1 subordination of subsystem if the invariability and independence from environment of the subsystem is directly or indirectly put into the maintenance-problems of the main system;] [theme 2 adaption of subsystem if, in other words, the subsystem serves a function in the overarching system]. [theme 2 of subordination Within the scope, that subsystems devote themselves to functions of the overall system,] [rhema 2 of adaption of overall system through subordinates it becomes structured specific to functions]" (Luhmann 1966a, p. 77).

As Luhmann (2014, p. 25) writes in the late 1960s on trust, when he says "only thus far, as the other human is not only content in the world, but steps into consciousness as an alter ego, as freedom to see things differently and act distinctly, the traditional self-concept of the world gets shattered, its complexity visible in a whole new dimension, for which at first no appropriate form of understanding and absorption is available", to see a "both… and", one needs to generate a new form of understanding. Gilles Deleuze, when talking about *How to recognize Structuralism*, too, pinpoints that precisely, when he says that "the first criterion of structuralism, however, is the discovery and recognition of a third order, a third regime" (Deleuze 2002, p. 171). This third regime shows up in many thinkers but prominently in Immanuel Kant (I998) when he in his *Critique of Pure Reason* introduced a third a prior or prerequisite to apprehending the world: "there is more at work than the single faculty of thinking" Kant (1998, A97) said "namely the understanding, and the understanding itself, as a faculty of cognition that is to be related to objects, also requires an elucidation of the possibility of this relation", a transcendental aspect. This analysis leads next to others to a series where "receptivity can make cognitions possible only if combined with spontaneity. This is now the ground of a threefold synthesis, which is necessarily found in all cognition: that, namely, of the apprehension of the representations, as modifications of the mind in intuition" (ibid. A97). All of Kant`s categories reveal this triplicity or seriality of three abstract operations, as well as the overarching trisection of time, space and the "pure, original, unchanging consciousness named transcendental apperception" (ibid. A107) that makes any integration of opposites and their "both… and" state possible.

The focus thus shifts to attempts for integration, of inner and outer, as shown earlier or in Parsons (1962) terminology: the cognitive orientation, the judgment of objects based on standards, and the appreciative value orientation, which "involves the various commitments to standards by which the appropriateness or consistency of the cathexis of an object or class of objects is assessed" (Parsons et al. 1962, p. 60), moves to a moral mode, where the impact on other action systems is assessed and how choices affect the integration of both, "his own personality system and the integration of the social systems in which he is a participant" (ibid. p. 60). The graduation of this stage might be the crossing over from reciprocal into interpenetrative in Terri O`Fallons (2013, p. 19) definition of it where "the subtle interior and the subtle exterior begin to come together".

In the 1968 book *Trust*, "trust and familiarity are consequently complementary means of absorbing complexity and, like past and present themselves, chained to each other. The unity of time, which separates past and future, however relegates them to each consecutively, and allows such a relationship of complementary accomplishments, where one of them requires trust and the other all the same familiarity" (Luhmann 2014, p. 26) – they, trust and familiarity, serve integration and are integrative parts of each other. So, while here sentences are connected through substituting the earlier ones through abstracting, e.g. thematizing it as "unity of time", the overarching grammar moves from parataxic or equation-like "arranging side by side" or using additive conjunctions like "and" – the syndetic parataxis –, towards hypotaxis, which means as much as "arranging under", by using subordinating conjunctions like "if…", "however", "where" or "even if" and auxiliaries like "would".

However, in the same way as in Luhmann`s *Right and Automation* we can see two distinct grammatical styles mixed in *Trust*. Why is that of importance? If we take standard sentence completions from the pluralist stage, they mainly fall in two categories: those which are simple parataxis or nominal phrases like "Raising a family… [nominal as is what? is a source of great pleasure, lasts too short a time, and is unpredictable]" (Hy & Loevinger 2014, p. 20) and nominal and accusative combined like in "People who step out of line at work… [nominal as is what? need to be examined individually to see] [accusative of who or what is being or verbed? both what the stepping out of lines means to them and also what it means for the organization; appropriate action can follow such an analysis]" (Zavarella 2009, p. 56). Contrary to this the Autonomous stage`s completions start to include more complex grammar and more grammatical cases reminding of Luhmann`s 1964 Achiever-like writing. For example, a sentence completion about a person stepping out of line at work at the Autonomous, i.e. Strategist, stage reveals grammar that is less action-oriented or accusative and dealing with ergative agents, but is revealing a dative-oriented structure, the case of the indirect object, which is together with the genitive of most languages indicative of possession, similar as some forms of the Latin ablative. They designate concrete or subtle spaces as the source or place from which or the time when something happened. It basically modifies nouns, pronouns and adjectives, and can be identified by the question: "Whence? From where or whom?"

So, "people who step out of line at work… [what? may be acting] [from where or whom? from a variety of motivations, some due to unresolved issues of their own, others due to genuine inadequacies in the work environment]" (Zavarella 2009, p. 61), are doing this because of some sort of being possessed by exteriors reverberating in themselves, or "people who step out of line at work… [what? are often demonstrating that something is wrong] [locative as where or wherein? in their work situation, personal life, interpersonal relations or that their goals and values about work are different than other people's]", and thus a recognition of projected internals moves into place, that is pointing towards the place where interpenetration in the sense of O`Fallon (2013, p. 9) where "one understands projection and introjection" seems possible.

Grammar in 1968 and 1969: Pluralist vs. Autonomous

Luhmann`s criticism and questioning of the conventional "means/end-considerations together with their mathematical intermediary-calculations" (Luhmann 1966b, p. 93) between 1966 and 1968, has to make place for the turn towards a conscious preoccupation and interpersonal mode that is "a transcendental reflection […], which does not base its arguments on the complexity of social systems, rather on top of the through it enabled complexity of the world" (Luhmann 2014, p. 27). The accusative construction with the ergative agent that is verbed as an additive series of "both… ands", that is "a conception of rationalization that brings together the social-sciences` and the business-administration's research areas" (Luhmann 1966b, p. 93), where "the whole interaction of task description and organization, formal behavioral rules and informal orientation, administrational large scale planning and small tricks, which one learns at the work-place, social reconstructions and unresolvable habitual carriages, which have to be carried personally" (ibid. p. 93) is transcended and included by a new grammatical style and thematic orientations. However, this transcendental reflection that is added, and is reminding of Kant, is not directed towards ideas, but the possessive construction starts to add first elements of locative, ablative to the dative and genitive framing – which historically have fused e.g. in Greek (Blake, 2001) – and thus is rather directed towards "[what? Stabilizing] [series of accusatives of who or what is being or verbed? systems in processes of intersubjective communication, which can apprehend and reduce more complexity of the world, and direct one's trust] [dative or ablative to whom? towards the functioning of these systems.] [Ergative agents as who or what is being or verbed? Only this way the transcendental process of world constituting and meaning can be directed] [dative as to whom or whereto? towards a higher stage of complexity]" (ibid. p. 28).

While in the accusative phase the hypotaxis superstructure, subordination of one clause to another, is much based on causal relations and auxiliaries, e.g. for Luhmann an extended "both… and" term of rationality "[has benefits,] [condition or reason because] [otherwise these factors, which co-constitute the decision process and outcome, cannot completely be considered]" (Luhmann 1966b, p. 94), that a system can be sustained "[condition or reason if] [both the code of conduct is minded and the means are fulfilled" (bid. P. 94) or "[structuring a system towards prefabricated ideas,] [hypothetical auxiliary would reduce the capacity for complexity equally]" (ibid. p. 94), connectives become formative for contexts in 1968. This new structure of conjunction by concession, comparison and prepositional phrases as adjectives shows up for example here: "[It has to be assumed that] [prepositional phrase as adjective with growing social differentiation other elemental] [comparison as well as more demanding mechanisms become reflexive] [list of examples – the venality of money] [comparison is in the same way as the investigation] [prepositional phrase as adjective through reflexive sciences] [comparison like epistemology, logic and methodology]" (Luhmann 2014, p. 77).

The prepositional adjective phrases seemingly substitute both the use of nouns and prepositions plus verbs and comparison as well as listing structure moves beyond additive rows and "both… and" notions and the statement of absolutes and exclusives, within Luhmann's writings of 1966, where for example "[It has to be exposed], [condition that already the] [additive phrase of nouns foundation of all decision-programs, the definition of the law-constitution, and the last means of the system,] [both and phrase are both at the same time, solution] [preposition with noun for the problem and definition] [preposition with noun for the problem]" (Luhmann 1966b, p. 94).

So, here we have to move back towards thinking about how coherence between sentences is created, too. We already mentioned that sentences are no longer processed as equations after the nominative period following the early writings of Luhmann, but by a process of integrating through abstracting parts of the earlier sentence into the later. This shift from rhema to theme, develops, too, with an intermediary step in the accusative phase: here the connection is mostly created by repeating a phrase from the earlier sentence, or a hyponymic – subordinate expression – or again through causal connectives. Coming back to Luhmann`s 1966 idea of transcending the rational means/end point of view, we can look at this development. There he writes, that "[rhema 1 a so far reaching, functional and dysfunctional, manifest and latent aspects of action apprehending theory of systems-rationality endeavors […] not basically to reach exclusively right solutions.] [rhema 2 with hypothetical connection through auxiliary Would one in this theory oblige oneself previously,] [theme 1 to deliver exclusively right action-rationality,] [rhema 2 connected through causal connective if one is given value-parameters and situational-variables, it] [would be necessary to make strongly simplified and not seldomly unrealistic assumptions.] [hyponymic expression of rhema 2 The capacity for complexity would be reduced a prior by a preliminary decision and would especially sink below the level necessary for the realm of public administration]" (Luhmann 1966b, p. 100).

In the same way as in the 1968 *Trust*, the critical evaluation of simple rationality moves towards intersubjectivity, the interrelationship between sentences moves towards the mentioned mechanisms of abstraction, or synonymic and context expanding or setting lexical operations of rhema-theme interaction: "[rhema1 One knows or anticipates that there stand, behind all object-experience, possible statements and behind all statements processes of human information-processing and not something like the unchangeable truth of being.] [theme 1 as abstraction or notion of synonymity with These processes are in principal intersubjectively controlled,] [rhema 2 as accusative shall transmit knowledge accessible for everyone] [rhema 2 expansion as contextual comparison and are by this independent of certain societal structures, particularly from higher status based on others, for example religious, political or economic, functions.] [theme 1 These principles of intersubjectivity,] [rhema 3 as possessive context and therefore the detachment of certain pre-given societal structure grants a degree of certainty of assertions and in this contemporary meaning their truths]" (Luhmann 1968, p. 61).

It is just in 1969, when Luhmann published *Legitimation through Proceedings*, where lexical cohesion starts to coincide with what he expressed in *Functions and Consequences of formal Organization*. In the same way as in this 1964 book, goal-orientation as the differentiation of organization and adaption of sub-units, became transparent, Luhmann first mentions three spheres of existence. He writes that "within closer inspection it is possible to recognize in the distribution of complexity onto different, functionally specified procedures a temporal and factual order, which both serve the integration of the overall system" (Luhmann 2017b, p. 245). One special type of rhema to theme shift here is antonymic. Seemingly the underlying structure or the superstructure in this part of a stage is that of ambiguity, synthesis or comitatives. We have already talked about trust using Luhmann`s words, but trust as emotion is considered as a variable to stabilize boundaries, too, by Luhmann in 1964. There he writes that emotions are personality functions and thus at first without social task. However: "[rhema 1 They don`t contain in themselves any guarantee to serve the sustainment of social systems, that they stabilize behavioral expectations for the purpose of the social order, within the scope of institutionalized norms and in harmony with other humans.] [antonymic rhema 2 Nevertheless, emotions can eventually find a personality-improving form, if the social order chances for expression.] [synthetic rhema 3 Thereon knot the possibilities of social-control of emotion-formation]." (Luhmann 1964, p. 373).

The same antonymic and synthetic interlacing is present in 1969, however much more complex. The grammatical markers, the locative and instrumental cases, are present again in *Legitimation through Proceedings*. Proceedings are means by which the interplay of emotion, as frustration or disappointment, and learning is hold within the social sphere. Here, the idea of intersubjectivity as what creates and sustains truth is further elaborated as a certain technique for integration contrary to that of differentiation Luhmann dealt with five years earlier. We can see the antonymic structure of coherence here: "[Rhema 1 The political system of a society can sustain high in-built-complexity and therefore the ability, to bring the not even remotely comprehensible number of fast fluctuating problems of society towards a decision, if it distributes the with it associated carriage of selection.] [Rhema 2 dealing with antonymic perspective An authority, even a hierarchy, could only intake relatively sparse information, could only absorb few contradictions and would decide quite primitive.] [Rhema 3 synthetic Complex systems have to be institutionalized through an interplay, which each operate under different circumstances, labor under different criteria of rationality and put into commission, which however in their strings presuppose each other reciprocally and are integrated by this.]" (Luhmann 2017b, p. 244).

Within these quoted sentences, one can, too, see how the prepositional phrases as adjectives like "that [preposition with] [adjective growing] social differentiation" grow into prepositional phrases as adverbs, like "[verb put] [preposition into] [noun commission]" or "[verb to bring] [preposition towards] [noun a decision]", where no longer adjectives are modified by nouns, but adverbs modify verbs and other adverbs – giving further information about them. We already pointed towards this, when we said, that the 1964 writing is drenched with cases modifying verbs. Hence integration in proceedings "[locative modification of verb as wherein? is expressed therein]" (Luhmann 2017b, p. 245), when it comes to time, and "[instrumental modification as by which means? ordered through]" (ibid. p. 245) when it comes to the factual definition. By this, both differentiation and integration – again as in the *Formal Organization* – are built up through levels. However, not through systems and sub-systems but through "the differentiation and the reciprocal recognition of procedural-types as components of the overall system [which] are generally institutionalized in abstraction from the interest-situation that determines, in the individual case, the introduction and implementation of a procedure; the concrete coordination of the takeover of past output as input is ensued by a case by case distinction" (ibid. p. 246).

The third, in Luhmann`s writing from 1966 to 1969, is like Deleuze`s idea of a third, which he sees in the structuralists` writings as "not just the real and the imaginary, but their relations, and the disturbances of these relations, […] as the limit of a process in which they constitute themselves in relation to the symbolic" (Deleuze 2002, p. 172), the development of a layer that sees the limitation of the conventional means/end-orientation and mechanic thinking first, through a mode of being aware of "both… and" as well as adapting to non-linear events. Then, as the idea of multi-variate causality beyond simple linear systems, which is before the split and thus the possible institutionalizing of both empirical research into action-theories or "which actions can fulfil certain functions with what kind of follow-up-problems […] and which actions are system-rational" (Luhmann 1966b, p. 92) and can sustain adaption in certain contexts – thus he created a more advanced version of a pluralist goal-orientation. In the third phase intersubjectivity and the enabling condition of trust and familiarity for hermeneutics came into play, which gives rise to a certain truth and a so-called postmodern quasi myth (Angus, 1990) which "makes independent from specific individual interests and coherence of experience" (Luhmann 2014, p. 34). While this third period enables integration, the idea of proceedings goes one step further and not only locates within an identity and creates instrumental means/ends-categories of the temporal, factual and integrative or social order, but elucidates how to sustain a system no longer through only maintaining its differences or boundaries but through "legitimizing itself through proceedings […] which can, within functional differentiation," (Luhmann 2017b, p. 253) achieve "both… and" adaption to their environment and "the justice driven adaption of the environment to the system" (ibid. p. 253). However, in these proceedings, we, can already see parts of the next stage: as similar to the first seeming pluralist book Luhmann published, there is an opening of the inside and outside boundary visible, that is not present in his book *Concept of Purpose and Rationality of Systems*.

In this book, published between *Trust* and his 1969 writing, Luhmann moves away from a value-orientation of what he calls the "transitivity of values" (Luhmann 2016, p. 43), where for him trust and familiarity were on top of an intransitive value-hierarchy – a postmodern myth as we said: one that prioritizes without stating it – informing "informing a value-relation regarding the effects of actions" (ibid. p. 44). Still in the grammar of the third period he writes that "[theme determination of purpose implies, [whom to is the value or whose value that the value of the intended purpose can,] [context setting as genitive independent of the values or unworthiness of the side effects] [comparison centering around genitive respectively the assigned purposes of other actions,] [preposition as adjective pointing towards a for whom or what? be justifying for an action]" (ibid. p. 44). And by this moves into the differentiation of means and ends or purposes, because, as he says in the fourth period style, [theme purpose-orientation does neither want to negate other values nor tries to generally subordinate them] [locative of wherein within a certain interdependency of preferred values]" (ibid. p. 48) as its "[what is its most instrumental characteristic? functionally most signifying characteristic lies] [three locatives of wherein within its mediating double-posture within the context of causality and within the context of values]" (bid. P. 50). Here, in concordance to the concern for autonomy (Cook-Greuter 2010) of the autonomous stage, "[theme autonomy has to be generated] [instrumental of by which means? through processes of selectivity, which] [preposition as adverbial as by which means? select with the proviso of their content`s information, a system is] [ambivalence – of course always only more or less –] [able to reduce environmental complexity, which means to sustain itself,] [polarization though it cannot completely overlook nor completely control its environment]" (ibid. p. 177).

It is in Luhmann`s 1970 book on *Sociological Enlightenment*, a series of essays he continued for the rest of his life, where this incline between system and environment regarding the degree of available variety and complexity completely moves into a discourse, a relation of two sides of a coding, prepared by the proceedings. As Luhmann wrote there, that once people thought that "that out of non-being cannot rise that which exists, nor out of uncertainty certainty […]. In actuality however, […] the modern society has reached a degree of complexity, through which what was thought as impossible can become possible and therefore has to be thought, too" (Luhmann 2017b, p. 252), but this still needs principles of integration. Or as Jürgen Habermas (1990, p. 165) states in Moral Consciousness and Communicative action "the orientation to principles of justice and ultimately to the procedure of norm-justifying discourse is the outcome of the inevitable moralization of a social world" happening through stage growth. The movement from moral Stage 5 to Moral stage 6 thus is signified for him by shifting from looking for principles to "orientation to procedures justifying norms" (ibid. p. 167).

However, as different Habermas and Luhmann are, later does not start to think about norm-justification but about the justification of systems. Here Luhmann writes that four factors have to be overcome in their isolation and have to be seen in their coherence (Luhmann 2018c). Namely to lay bare the inner correlation of a) differences in perspective between a first and a second person, as incongruities, that serve as causes for adaption, b) latency as disregard for certain aspects of reality to orient towards goals, c) the necessity to move from univariate thinking towards a systems-theory to free the actor from being judged as deliberately ignorant and "living in a really cunning reality, as purely being a beautification of ignoble motives, but as [living within] uncomplete selection, as alto drastic simplification of a much more complicated actuality" (ibid. p. 86) and d) a functional orientation towards sustaining systems in a complex world: to live the idea of enlightenment "as expansion of the human ability to, capture and reduce the complexity of the world" (ibid. p. 81). Sentences here again become simpler – or better said: adapt into a new order of complexity – and nominal in their structure, equation-like or homonymic in their interlacing and referential between rhema and theme through pronominal cohesion, but now don`t hold a "both… and" view but a "both… and… and the relationship of both sides to each other"; we can see this in this passage, where Luhmann thinks about the maintenance of systems at the archaic stage of development through "[rhema 1 'small' problem solutions, quantitatively reduced in regard to both, people and things.] [theme 1 with simple equation-like reference Thereby, and that is structurally very important,] [rhema 2 as "both… and" two strategies of accumulating and accommodating] [rhema 2 the what or relationship they are in stand in functional equivalence and contradiction. They on the one hand provide alternatives and therefore options of reduced complexity; on the other hand, they block themselves]" (Luhmann 2018c, p. 273). As we can see, the two strategies of accumulating and accommodating stand in a relationship which is again a "both… and" of a more intricate kind or as Cook-Greuter (2010) writes: "at the Autonomous stage the identification with polar opposites is still sequential […] [, while] in contrast [at the Construct-Aware stage], the same dichotomy can be integrated, and non-defensively appreciated as two sides of the same coin" (p. 77)

The grammar here fits some of the examples of Susanne Cook-Greuter`s (2010, p. 76) fourth scoring category for the Construct-Aware stage of ego-development, where one has "explicit awareness of perceptions, definitions, labeling, assumptions, frame of reference, paradigms and structure in meaning making. [Which means, one is] aware of the constructed nature of self and reality, of seeing the constructed nature of reality": People who step out of line at work… "[theme 1 as first side of "both…and" sometimes are only that – out of line –] [rhema 1other side of "both… and…" and other times can help,] [relationship as "both… and" by how and when they step, to redefine a more workable and appropriate line]" (Zavarella 2009, p. 66), "I am… [rhema part one as definition of relationship – a confusing complex of contradictions –] [rhema part two as "both… ands" both good/bad, assured/self-doubting, aloof/warm at the same time" (Cook-Greuter 2010, p. 77) or "A man`s job… [Rhema 1 as "both… and" relationship notion has traditionally been the role of 'breadwinner', but such simplistic labeling ignores an almost infinite number of possibilities,] [rhema 2 as "both… and" limited only by that man's conceptual model of himself and his world]" (ibid. p. 76).

However, what changes here is not only that there is a permanent awareness of how "both… ands" relate to each other. Besides, with the fourth function coming into play, that of maintaining patterns or self-thematizing, which substitutes the earlier attempts in Luhmann`s Autonomous writing, we can recognize that this assumable Construct-Aware logic looks much more like the fourth period than the writing in 1966. Strictly speaking the "both… and" period of Luhmann`s lifework differs by not using as much an instrumental framing of itself and the pointing to antinomies, but it is primarily about "understanding from" (Luhmann 1966a, p. 10). That points to the third and dative phase, instead of that of instrumentals and locatives.

Intermediate Contemplations

Since we now have dissected one complete grammatical cycle, we can contemplate these findings and add to them more granularity and additional context to place them in an overriding conceptualization of human stagewise development including: a) the fact that each developmental stage to be completed has to run through the four depicted phases, b) that not only the lifework of authors move from nominal to accusative to dative and modifying grammar but, too, a complete stage of ego-development includes all four basic semantic types as well as other models like Kohlberg`s psychology of moral development can be reconstructed in their stage and in-stage distinctions by using them, and c) a fractal structure of tiers, stages and phases that is d) accompanied by elaborating a broad consensus of thinkers at the Construct-Aware or any later stage. Afterwards we embark into a less grammatical but thematic analysis of Luhmann`s second and third phase of his writing marked by the 1984 *Social Systems* and the 1997 *Society of Society*.

For this we first show the interrelationship of the analyzed grammars with other lexicogrammatical components we hypothesize to be part of textuality of certain phases and stages of development. These phases are hypothesized as domain general and thus useful to reconstruct and reappropriate any existing developmental scoring system as long as one gets the boundaries of their respective levels right. We theoretically offer a model with features that are "necessary and sufficient conditions […] are not accidentally true […], but that are rather rooted in the human 'language capacity,' and thus constitute the innate organization […] of this [human] experience" (Chomsky 2006, p. 24) as universal grammars that relate to multiple other universal hierarchies discovered in linguistics. And thus, they would allow, as Theo L. Dawson (2004, p. 3) writes in regard of the benefits of such universal measures, to "(1) meaningfully compare development across domains and contexts, and (2) examine the relationship between developmental stages and conceptual content".

The first following section, too, exemplarily underpins the fact that each ego-developmental stage has to include all four grammatical phases which makes the Pluralist, i.e. 4.0, and Autonomous, i.e. 4.5, stages two halves of the same stage since both only include half the amount of grammars than all earlier ego-levels do, a fact that we further model in the third section of our intermediate contemplations. Thus, a series of four instead of five stages arises from Expert to Construct-Aware fusing Pluralist and Autonomous. Given that this stage deals with the function of integration we suggest calling it Integrative. For completion we show, too, that Ann Colby`s and Lawrence Kohlberg's (2010) *Standard Issue Scoring Manual* aligns with both the grammatical cycles and the new stage distinctions.

The second subsection of our intermediate contemplations depicts semantics webs and thus points to the multiple paths through the four grammatical phases. It, too, argues for new tier boundaries that pay credit to a) the fact that Pluralist and Autonomous should be combined into one, the Integrative, stage and thus a pattern of four can only unfold when Construct-Aware is included into a tier with the Expert, Achiever, Pluralist and Autonomous stages and to b) the observation that there is rich evidence that part of the Construct-Aware thinker`s predicament is to complete and reflect on the completion of a quadruplicate cycle that mirrors Parson`s and Luhmann`s four phases of adaptative, goal-oriented or differentiating system and environment, integrative and latently pattern maintaining or self-thematizing.

In the third subsection that prepares the voyage into Luhmann`s writings that display Construct-Aware and Unitive stage markers the pattern of fours is included into a larger Tier structure composed of four tiers. This structure can be found in the German philosopher Georg Wilhelm Friedrich Hegel's work as well as in that of the Indian mystic Sri Aurobindo and that can be approached by the terminology given by the American pragmatist Charles Sanders Peirce.

Contemplations on Grammar and Phases

In the 1975 *Systems-theory of Society* Luhmann depicts the level-differentiation of society. He writes that "a meaningful self-thematization of society can only be complete, as long as it projects its object on all three horizons" (Luhmann 2017a, p. 264). Then society becomes "in temporal perspective evolution, in factual perspective systems-differentiation and in social perspective communication" (ibid. p. 264). However, all three layers are communication, given that society for Luhmann is defined later on as letting go of the idea of intersubjectivity "that must be superseded by the concept of a self-referential-closed system of societal communication" (Luhmann 1995, S.50). Already in 1975, he sees the intersubjective just as a certain evolutionary step, a specific social system of society as "the social process of intersubjectivity which is self-constitutive" (2017a, p. 674), and communication as what is a foundational part of evolution. Hence, the third layer he describes under the head of self-thematization is best called integration or the social sphere.

This interplay of three dimensions is, too, a marker for the Construct-Aware stage as depicted by Cook-Greuter (2010) in her Dissertation about *Post-autonomous Ego-Development*. As Ken Wilber writes in *The Religion of Tomorrow*, it is the Indigo altitude, which "possesses all four Quadrants, or dimension perspectives" (Wilber 2018, p. 521), and the Construct-Aware altitude is just one step away of this. Additionally, here Luhmann recognizes self-thematization of systems which can be seen as "the subtle objects majoring to causal [meta-aware] objects" (O`Fallon 2013, p. 20) as an awareness of awareness is a requirement to do so.

Besides this cross-referencing of these three models, and others, with our enactments and observations of the implicit stage structure in Luhmann`s work, we have revealed up to now four grammatical styles which relate more or less to Barry J. Blake`s (2001) hierarchy of relational grammar, the sophistication of bringing together subject, predicates and objects in complex sentences which moves from a) subject, to b) direct object, to c) indirect object and culminates in d) oblique forms with instrumental and locative cases. This natural hierarchy or sequence is paralleled by that of Nominative (Nom) to Accusative (Acc) and Ergative (Erg) to Genitive (Gen) to Dative (Dat) to Locative (loc), to Ablative (Abl) and Instrumental (Inst). But as we have pointed out earlier one has to keep in mind that neither English nor German have all of these cases. Or, as Luhmann writes: one has to see this not as static and linear, but closer to reality "would be the form of a labyrinthic diagram, of an artwork, of a memory, or a note box with multiple entries, centers and choices of routes" (Luhmann 2017a, p. 266) when it comes to depicting the relationship of self-thematization – in this case of consciousness-development and grammar – and the differentiated layers and phases.

Nonetheless it seems useful to point towards additional parallels with linguistic hierarchies. For example studies of childhood lexical development regarding connectives, as Jacqueline Evers-Vermeul (2005) recapitulates in her dissertation, moves through four phases either when it comes to the acquisition of connectives and clauses as well as domain integration: growing from a) positive additive to b) negative additive and positive causal and positive temporal to c) negative causal and temporo-causal before becoming d) adversary.

This hierarchy as labyrinthic processes which we suppose is hypothesized to iterate with each stage as well as within each of the later depicted tiers thus showing the same universal patterns repeating with increased complexity or emergent properties and objects. For completeness a stage moves through four grammatical distinct phases, which overlap and fluctuate as the evolutionary process they are. The grammatical types can be classified through Carlo Quiles`s and Fernando López-Menchero`s (2017) *A Grammar of the modern Indo-European*, William Croft`s (2003) *Typology and Universals,* Kreyer`s (2003) *Genitive and of-construction in modern written English* and Blake`s (2001) *Case*. The phases are demarcated by phrases from Luhmann which originated in the particular phases and point towards their containment in the larger order of Luhmann`s quadruplicity introduced in the introduction to section *3. The Discontinuities in Luhmann`s writings.* Figure 2 depicts the hypothesized fractal structure of phases and stages. In the final section of this article the fractal structure is unfolded across all: phases, stages and tiers.

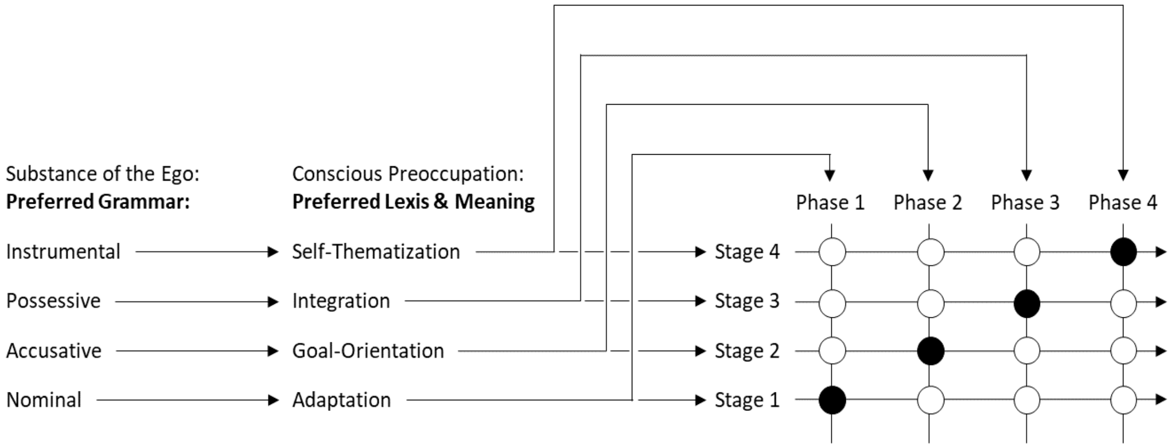

Figure 2. Fractal structure of stages and phases within one tier; the black dots symbolize where stage and grammar collapse - the most essential and stable phase within a stage?

1. A first – adaptative – grammatical phase as the Nominative where "the displacement of complexity from the interior decision-behavior to the system-structures foregrounds yet unknown demands" (Luhmann 1966a, p. 10) where there is only the underlying, the subject, but not as an object: the case of the subject of a sentence and predicate nominative which can be a transitive verb either. It is revealed by the question: "Who or what?"

2. A second – goal-oriented or differentiating system from environment – grammatical phase of the Accusative beyond others serving to review the who or what that is being verbed "the realm of solution-possibility and follow-up-problems" (Luhmann 1966b, p. 105) as direct objects: so to speak, the accusative is the case of these direct objects of a verb. It is also used with many prepositions. It is revealed by the question: "Who or What is being or verbed?" This includes:

    a. The instrumental- or locative-like version which indicates place to which, extent or duration as well as the case which identifies the agent or the intentional performer of an action of a verb.

    b. The ergative-marked noun phrases marking encoding agents.

    c. The Genitive: the variations of the possessive case which relate to subjective and objective or could easily be reformulated into nominal or accusative phrases. They are mostly not noun phrases modifying a noun phrase. They oftentimes, contrary to English, can be formulated as a single compound word in German and can be identified by the question: "Whose? From what or what of?"

3. A third – integrative – grammatical phase of the cases where, at the Autonomous stage, as Luhmann 1968 (p. 10f) points out, "world-plot and own identity, become to him [man] a component of his own system-structure and to a behavioral-basis, in so far as he experiences other people, which actually experience, what is possible for him, and who simultaneously identify him as object, so that he can adopt their point of view and identify himself". This phase seems to be the prerequisite for the subject to object move Robert Kegan (1982) depicts in *The Evolving Self*, namely where "what was immediate becomes mediated by a new immediate […], a differentiation from that which

was the very subject of my personal organization and which becomes thereby the object of a new organization on behalf of a new subjectivity" (Kegan 1982, p. 85). Which contains all cases recognizing to whom something happens or by whom something is possessed or some form of comparative and dependency. Including:

   a. The Genitive: the variations of the possessive case which cannot easily be transformed into nominal or accusative phrases. Noun phrase modifying a noun phrase and can be identified by the question: "Whose? From what or what of?"

   b. The Accusative: in its forms where it indicates indirect causality and hence substitutes or mirrors the dative as in "identify him as object" versus "identify an object".

   c. The Dative: the case of the indirect object. It also indicates possession, and beneficiary of an action. It shows up with ditransitive verbs and parataxic sentences and is revealed by the question: "From Whom? Whom or to What?"

   d. The Ablative or Locative which basically indicate a Dative: the source or place from whom or which something comes.

   e. The Prepositional: variations as adjectival prepositional phrases leading to comparative structures, contexts as well as denominating the receiver, often of something new, e.g. "is possible for him".

4. A fourth – self-thematizing or pattern maintenance – phase of those cases which all mark the same syntactic relation, that of optional modifiers to the main verb building prepositional phrases as adverbs and expressions, of "instrumental and expressive kind, which serve the solution of system-problems and in this sense the maintenance of systems" (Luhmann 2017b, p. 226). It is the difference of inside and outside, of experience and action and other dichotomies or antinomies that create location, direction and means as well as "meaning that is necessarily bound to this double-structure of selection" (ibid. p. 93). This fourth phase allows one e.g. at the Autonomous stage to be seen as "Identity, which is the means to sustain oneself in a complex and volatile Environment through stabilizing an Inside/Outside difference" (Luhmann 2016, p. 175). Expressing itself through discord and/or as concord and synthesis often in the form of or accompanied by categories e.g. "an instrument" or by "the instrument" or within "the place":

   a. The Ablative and Locative forms: the source or place or time wherein or towards which something happened which can be identified by the question: "Whence? Whereto?" As well as either physical or temporal places correlating roughly with prepositions like "in" and "under" thus create inside/outside, means/ends and layers which can be identified by the question: "Wherein? Whereunder?"

   b. The Instrumental: the case which signifies the means and the agent present in or while performing an action. It can be identified by the question: "How? With what or using what? By what means? With whom?" And, which includes expressing the agent of the passive and is almost always inanimate e.g. as the "proceedings" of 1969 in contrary to the first and second person "decisions in man and systems" and the "feedback on agents" of 1966a and the 1966b third person direct objects of certain empirical, rational, multivariate "schemes" and the incoming of the human and animate "intersubjectivity" of 1968.

c. The Prepositional: verbs that take on the form of a prepositional phrase indicating goal or dynamics between differential antinomies or comitatives sometimes followed by accusative as the attaining of a direct object as categories by which something can be intended or wherein something lies.

As Table 4 shows exemplarily for the Achiever, i.e. 3.5, stage: one can sort through sentence completion items and align them with these phases. Each of the major stages up to Pluralist, the Diplomat, Expert, Achiever, can be sorted using the four phases or a more process like view of multiple grammars adding to each other hierarchically.

Table 4. Four phases within the Achiever or Conscientious Stage of Ego-Development derived from Zavarella`s (2009) Item 27 "People who step out of line at work…".

			Sentence Completion
Phases & Case Structure			People who step out of line at work…
Increasing grammatical sophistication ↓	Phase 1 – Adaptative:	Nominal: "Who or What?"	*…are probably the most interesting.* *…are probably creative.*
	Phase 2 – Goal-Oriented:	Accusative: "Who or what is being or verbed?"	*...should be given a chance to explain their actions.* *...probably have something interesting to say.*
	Phase 3 – Integrative:	Dative: "To Whom or What?"	*…can sometimes have something different and useful to contribute to the organization.* *…are annoyances to the people they work for and should be prepared to seek alternative employment.*
		Genitive: "Whose? From what or what of?"	*…are often doing so to revel against unduly restrictive rules and regulations of their peer group.* *…sometimes have good reasons, others will need a firm word to insure their actions will not be repeated.*
		Ablative: "Whence? From where or whom?"	*...should be talked too, to find out why and if there is something to be learned from either side.*
	Phase 3 – Self-Thematization:		*...should be counseled as to how better to express their dissention while still being respectful of others.*
		Locative: "Where or wherein?"	*…need to be steered in the right direction and shown the effect their behavior has on everyone surrounding them.*
		Instrumental: "By which means? For which ends?"	*...should not necessarily be punished. The source for their action should be determined and investigated in order to resolve the problems upon which their behavior is based.*

As pointed out this approach does not work for Pluralist and Autonomous since the Pluralist stage as depicted by Loevinger and Cook-Greuter synthesizes its meaning on the basis of a nominal and accusative lexico-grammatical web while the Autonomous solely draws on the dative and modification web – thus, taking this approach makes them combine themselves into one stage. This than complete four phased stage, as said, might best be called the Integrative following Charles S. Pierce`s dictum in the *Ethics of Terminology* that the "the first rule of good taste in writing is to use words whose meanings will not be misunderstood" (Peirce 1988, p. 265). Indeed, this is necessary to avoid equivocation and provide "that the different meanings are remote from one another, both in themselves and in the occasions of their occurrence" (ibid. p. 264). Calling it integrative thus serves both ideas inherent in the dictum: firstly, it clearly shows the distinctiveness from the ego-development trajectory discovered and advanced successively from Loevinger, to Cook-Greuter and finally O`Fallon and secondly it pays credit towards the trajectory depicted by Parsons and Luhmann as well as many others as shown later.

By this the scope of this Integrative stage matches moral stage 4/5 and moral stage 5 as depicted in Lawrence Kohlberg`s (2010) *Standard Issue Scoring Manual for the Measurement of Moral Judgement*. As Table 5 (below) exemplarily shows, early versions of a moral stages tend to use nominal and accusative grammar, while later or second half version tend towards dative and modifying grammar – of course these are tendencies with some exceptions of crossing over into earlier or a bit later grammar, within a quarter of this four phased growth cycle. The examples in Table 5 stem from answers on the Heinz Dilemma, where a husband has to either steel a drug to save the life of his wife or passively watch her die.

After we now took a look at an expanded scheme of the grammars introduced under the heading *2.b.i Within a Sentence: Subject. Predicate, Object Variations*, hypothesized about the interconnection of them with other linguistic hierarchies and hypothesized a fractal structure of the overall developmental scheme and measuring scale we have shown the existence of all these grammatical types as a way to sort through sentence-completions of the Achiever, i.e. 3.5, stage of Ego-Development via increasing grammatical complexity. This served as an exemplary representation for the variety of lexico-grammatical overlays a stage should include for having the whole four phased range our proposed domain general scoring metric suggests as the universal width of a stage. By way of example we additionally have shown how Lawrence Kohlberg`s (2010) scoring scheme uses the same direction of growth throughout a stage however, not four phased but each stage split into an early and late version. The next section will give even more granularity to the grammatical superstructure or substance of each potential ego on the path of self-discovering a trajectory that is, too, depicted through the terminologies of more than a dozen scientists and philosophers in the following.

Table 5. Responses on the Heinz dilemma and their Grammar in concordance with levels of Ego-Development.

			Question on Moral Dilemma
Case Structure & Stage			Would a good husband think it is his duty to steal and Why?
Expert	Stage 2/3	Nominal and Accusative: "Who or What?"	*[Nominal part Well, I think it would if his wife is going to die,] [Accusative part he wouldn`t have much choice.] (Colby & Kohlberg et al. 2010, p. 19)*
	Stage 3	Instrumental and Locative: "Where or wherein? By which means?"	*[Nominal part as adjectival instrumental: "how was he?" He should not have been so selfish] [Comitative part with possessive with that drug of his, and I think Heinz did right] [Locative part as time when he did break] [locative part as interior into that store] (ibid. p. 22)*
Achiever	Stage 4/3	Nominal and Accusative: "Who or What?"	*[Nominal part as genitival accusative Because it is a matter of life and death,] [Accusative part it gets down to a matter of life and death,] [Accusative as temporal subordinate then you are balancing the financial greed of one person against a life.] (ibid. p. 32)*
	Stage 4	Instrumental and Locative: "Where or wherein? By which means?"	*[Nominal part as locative: "in" We like to believe there is something special in a human being,] [Dative part as possessive perhaps some spark of the divine,] [Comparative part something like this which it is wrong to kill.] [Nominal part as locative: "within" This is something within a person] [Instrumental part: "by which" that raises him above an animal, which removes him from being treated like an animal.] (ibid. p. 47)*
Pluralist	Stage 4/5	Nominal and Accusative: "Who or What?"	*[Nominal part The commitment to another person] [Accusative part: series of accusatives which involves a total commitment and, in a sense, he is taking the action because she cannot take it herself,] [Nominal part: a third which holds "both… and" in the sense of a marriage being this kind of thing, something in two bodies][Nominal part: conjunctive as equation and in that sense there is not much difference in terms of responsibility of her] [Accusative part trying to do something for him.] [Nominal part as both and That involves a commitment to each other and, too, some kind of form of life or something like that] (ibid. p. 49)*
Autonomous	Stage 5	Instrumental and Locative: "Where or wherein? By which means?"	*[Nominal part as locative …it revolves around what I was saying just now about rights] [Comitative part that kind of go with a human being,][Adversative part but really those rights have been defined] [Instrumental part: "by which means?" by us as people, by agreements that we reached through some kind of social process…]*

Contemplations on Semantic Webs

Terri O`Fallons stage theory is based strongly on the use of passive and active language. However, as we can see simplified in Table 4, the accusative phase of the active 3.5 or Achiever stage can take on passive form – there should be "given a chance" But more intriguingly is what happens in the dative or genitive phase where semantic structure allows the adding of some sort of a beneficiary by growing into a grammatical form which existed in Kalkatungu, an extinct Australian Aboriginal language, sometimes called the anti-passive. This term is derived from the recognition that it "is a derivation that allows access to the privileged relation" (Blake 2001, p. 57), to become not only patient but beneficiary – the object to a new subject, so to say, that might be outside of oneself. It is similar to cases like the beneficiary applicative and the instrumental or comitative applicative, where a participant of a sentence is advanced to assume the grammatical relation held by the patient including typical instrumental or comitative markers, too, to move for example "the internal orientation from patient into a manner" (Martin 2000, p. 392) or purpose expression or a direct object is stated in a way that it is a possible passive subject, e.g. "[passivized stepping out of line The source for their action should be determined and investigated] [purpose or reason for being passive in order to resolve the problems upon which their behavior is based]". It creates a move from actor or reflexivity to beneficiary.

But again, this is part of a larger hierarchy, where each phase can show a unique sort of passive structure complementing its active variations. This hierarchy of universals, too, forms a "semantic field with various diachronic and synchronic connections between all of the three [later, b) to d)] categories" (Gast & Siemund 2006) from a) intensifiers like "the most" including anti-causative or de-objective as passive and intransitive verbs to b) reflexivity e.g. in "given a chance to explain their actions" with impersonal forms of passive and transitive verbs, c) referential disambiguation, or variation of context, accompanied by adnominal intensifiers leading to so-called emphatic reflexivity like in "[the identity of accidents constitutes what signifies the temporal problematic of accumulation, namely the progress of the present as an ever actual moment, which cannot automatically] [adnominal intensifier 1 carry itself what it accumulates, rather has] [adnominal intensifier 2 with ditransitive verb to seek itself retention and accession]" (Luhmann 2014, p. 17) and di-transitive verbs – verb forms followed by two or more objects allowing for natural reciprocity – to d) role disambiguation through actor-oriented intensifiers, which are used to relate a proposition to a set of alternative propositions and by this create an 1) actor-role assigned to 2) an actor or instrumental category 3) other than the referent, thus managing full reflexivity by having 4) "a different thematic role in the alternative propositions, e.g. that of an external causer or beneficiary" (Gast & Siemund 2006, p. 14). A case form we can observe in Luhmann's 1969 writing: "[proposition 1 Thus far as systems start to orient on the basis of temporally distant effects] [actor-oriented intensifier by themselves,] [proposition 2 where system is negative beneficiary well, in regard to purposes, the present in itself becomes problematic]" (Luhmann 2017b, p. 226). This structure is contrary to the intransitive verbs of the first phase, too, signified by so-called derived intransivity expressing itself e.g. through "orient by themselves" which contrary to "to seek itself retention" lacks any necessity for an object, like intransitive verbs in the first phase do, either. The possibilities for expressed grammar are manifold and suggest that there are many variations of each stage including passive and active versions of grammar.

Obviously, the manifold possibilities opening up between the realm of lexis and that of grammar lead to certain lexico-grammars which carry the discourse of a culture within a certain stage as variations or differences and reappropriations. Exemplarily this can be shown using Luhmann`s (2016) depiction of a sequence of cause, effect, the values to whom both cause and effect exist and the judgment of means/ends by combining it with Martin Haspelmath`s (2003) semantic web for dative constructions from *The Geometry of Grammatical Meaning*. We can see the drawing, in Figure 3. This table illustrates some of the markers we have mentioned so far and how they can form different types of dative, using different indirect objects, in the third phase to depict the non-linearity and labyrinthic possibilities of grammar.

Figure 4. Hypotheses about Stages, Phases and a Semantic Web depicting some of the Grammars.

Contemplations on Stage Patterns

We hypothesized before that even though Terri O`Fallon`s stage theory proposes not only, and applies in its measurement, four phases but, too, offers overarching pattern of passive, active, reciprocal and interpenetrative, that her pattern within what she calls the subtle tier ends with the third phase of Parson`s and Luhmann`s patterns – as well as after three complete grammatical cycles not four. We can only exemplarily show that both stages basically have a "both… and" point of view, that only matures from nominal and accusative – the Pluralist – towards dative, possessive and modifications – the Autonomous – instead of a qualitatively distinct mode of operation and conscious-preoccupation with a new object and meaning within the quadruplicate scheme of adaptation, system and environment hence goal-orientation, integration and self-thematization. Table 6 depicts this exemplarily for two different modes of using the grammatical overly of "both… and": a positive as well as negative scheme and a two positive sides of what would be a polarity at the Achiever stage.

Table 6. Difference and oneness of Pluralist and Autonomous depicted by examples from Miniard 2002, p. 60ff.

	Pluralist/4.0	**Autonomous/4.5**
	responses including Nominative & Accusative:	Responses including Dative, Possessive & Modifications:
Three meaningful and differential components as "both… and" as positive & negative:	A good boss… [Theme as first side of pole: positive as Nominative: "Who or what?" *Demands excellence*] [Rhema 1 as second side of pole: Negative as Accusatives: "Who or what is being or verbed?" *but provides for the development of the skills and attitudes]* [Rhema 2 as Accusative: "Who or what is being or verbed?" *necessary to achieve it.*] (Miniard 2002, p. 61)	A good boss… [Theme as first side of pole: positive as Accusative: "Who or what is being or verbed?" *keeps lines of communication open and provides direction for activities*] [Rhema 1 as second side of pole: Negative as Locative-like Dative: "Onto whom or what?" *without impinging on the employee's own abilities & desire*] [Rhema 2 as Possessive: "Whom or what?" *to direct their own activities.*] (Miniard 2002, p. 70)
Three meaningful and differential components "Both… and" as two positive poles:	A good boss … [Theme as Nominal "both… and": "What?" *both supports and challenges,*] [Rhema 1 as first side of a pole – supervises: Accusative: "Who or what is being or verbed?" *uses a variety of supervisory methods and*] [Rhema 2 as second side of a pole – diversity or freedom: Accusative: "Who or what is being or verbed?" *cherishes diversity.*]	A good boss… [Theme as Instrumental Categories: "Has which means?" *has a clear sense of self and a vision of a future state – both*] [Rhema 1 as first side of pole: Comitative: "With whom or what?" *which are compatible with colleagues, co-workers and with the organization*] [Rhema 2 as second side of pole: Instrumental: "through which means?" *and which are conveyed to others through example, not words.*] (Miniard 2002, p. 70)

We already pointed towards the end of Terri O`Fallons iterating cycle in the subtle tier with Luhmann`s third and fourth phase within the Integrative stage of his life work, i.e. within the Autonomous stage, when we, too, pointed to Kant`s way of integrating inside and outside. Most famous for dealing with projections is Carl Gustav Jung. When he writes in *AOIN Research into the Phenomenology of Self*, that "although, with insight and good will, the shadow can to some extent be assimilated into the conscious personality, experience shows that there are certain features which offer the most obstinate resistance to moral control and prove almost impossible to influence. These resistances are usually bound up with projections, which are not recognized as such, and their recognition is a moral achievement beyond the ordinary" (Jung 1970, p. 9), Jung moves seemingly exactly from a fourth-phase grammar, using adversative conjunctions as well as locative and comitative modifications, into a more nominal style of the early Construct-Aware, i. e. the 5.0 stage of O`Fallons model characterized by an "insight around projections in one`s interior experienced in the moment. The witness (awareness of awareness) is activated and it becomes aware, in the moment of projections arising" (O`Fallon 2010, p. 60).

Looking at Luhmann`s understanding of his four phases adaption or the temporal dimension and self-thematization as the maintenance of identity show up as opposite sides of a coin, as major polarities or antinomies: While "adaptation as a learning process, reflection [as self-thematization] is a constituting process. In the process of adaption contingency has to be understood as 'dependency from…'. Within the process of reflexivity contingency has to be understood as non-necessary possibility. Classically framed: Causality and freedom are not mutually exclusive, rather different expressions for the process of contingency" (Luhmann 2017a, p. 920f). So, there arises less the iterating movement from passive to active and the passive receptive to the active interpenetrative but more of a polarity between the first and the last and that of individual goal-orientation and integration.

That reminds of the great polarity Friedrich Georg Wilhelm Hegel (2011) points out in his *Encyclopedia of philosophical Sciences*, when he comes to his perspective on psychology and the subjective as well as the objective mind. In the passages about the objective mind he spans a trajectory of moral maturation from right or law, over morality towards the ethical life. The sphere of right subsumes or synthesizes two types of psychological functioning: the consciousness which has the soul as its object and the mind "which declared itself to the truth of the soul and the consciousness" (Hegel 2011, §440). Within the right the free will of mind, which has its destination still on the outside, has to direct its means towards the end of ownership. This is only possible based on consciousness which itself is, "by itself and for itself, the change of the object. Consciousness appears therefore differently established determined following the difference of the objects" (ibid. §415) and is in its more mature form of self-consciousness an "I = I […] in which the I merges with itself [as on object of desire] and becomes satisfied by this, becomes a real" (ibid. §§424 & 428). It is like Luhmann`s view on adaption as it is adaptative and dependent on what is in both "the subject and the object identical" (ibid. §415). Consciousness matures towards reason and the mind, which as free will "directs its inner destination and purpose on an externally found objectivity" (ibid. §483), and from an orientation towards right into morality. But as morality is based on an "infinity of subjectivity" (ibid. §511), on the recognition of the uniqueness or specialness of everyone, it creates both a highly relative world and the need for relational modes of understanding. Hegel (2011) mentions dialectics as such a proceeding but as Karl Ott Apel (2016) points out in his essays on *Discourse and Responsibility*: there is a necessary and next step which is especially grounded "in the Hegelian presupposition for the possibility for truth" (Apel 2016, p. 72f). This possibility for truth shows up in the *Encyclopedia* as "the truly ethical life […] [where] the disposition of the individuals is the knowledge of the substance and the identity of all its interests with the whole" (Hegel 2011, §403). Here, the individual and self-conscious freedom is directed as "un-intermediate general reality and simultaneously custom […] to create both through its occupation" (ibid. §514). This ethical substance can, too, be called trust: as each knows anyone else only within the shared whole and as shared identity. It is again and in the same way as for Luhmann a oneness of inside and outside, but where it first came from the outside towards the receiving end of the inside it is now the inside or shared substance which is directed outwards.

One can find this pattern in the writing of the Indian saint Sri Aurobindo, too. At the end of the trajectory of separate self is an intermediate stage which is not yet completely spiritual but no longer completely mental either: the higher mind. "This higher mind is able to perceive and deal with other souls as other forms of its pure self" (Aurobindo 2005, p. 181) in the same way as for Hegel the truly ethical life arises, when "inside touches inside". More mundane formulated by Kohlberg: being at moral stage six means having "the perspective of any rational individual, that acknowledges the essence of morality or acknowledges that any human contains within itself its end-purpose and has to be treated accordingly" (Kohlberg 1996, p. 132). This reverberates what Abraham Maslow (1993) considered extraordinary in the rare individuals he discovered and named self-actualizing. "They tend to agree about what is right or wrong, as if they were perceiving something real and extra-human rather than comparing tastes that might be relative to the individual person" (Maslow 1993, p. 9). Not only has Kohlberg four abstract stages, but Abraham Maslow, too, creates a seriality of four distinct modes of psychology: namely as first behaviorism, as second the cluster originating in Freud, and the "'Third Force' […] that includes the first and second group" (ibid. p. 4) as humanism plus the fourth of transcendence. Aurobindo, as well, one might suggest has a four-phased pattern as the higher mind as the intermediary integrates the mind proper which "is divided into three parts—thinking Mind, dynamic Mind, externalizing Mind – the former concerned with ideas and knowledge in their own right, the second with the putting out of mental forces for realization of the idea, the third with the expression of them in life" (Aurobindo 2012, p. 177). For this mind proper, there, too, again is an intermediary necessary – the mental vital, connecting the mental with the physical life.

As Hegel (2019a, p. 746) himself writes in the *Science of Logic* "the term counted as third can also be counted as fourth, and instead of a triplicity, the abstract form [of dialectics out of thesis, antithesis and synthesis] may also be taken to be a quadruplicity; in this way the negative or the difference is counted as a duality". Despite Hegel himself staying with the form of triplicity for esthetical reasons or because "it is this unity, or that the entire form of the method is a triplicity, is indeed nothing but the merely superficial, external side of cognition; […] because it has always been recognized to be the universal form of reason" (ibid. p. 746f), the Slovenian philosopher, cultural critique and lacanian psycho-analyst Slavoj Žižek (1999), too, extracts this quadruplicity in his book *The Ticklish Subject.* This leaves us with a tier pattern as depicted in Table 7 which is according to Žižek (1999, p. 80) "the longing for reconciliation with a lost totality, […] the fourth moment, ethical substance, 'second nature'". We depicted the phases including some of the here mentioned authors, to show, how theses phases are reappropriated in different and unique ways with even using the same words for other phases. As shown semantic webs can take on different form thus different people supposedly perceive same a prior grammar through a different lexical field.

Table 7. Patterns of the phases based on Hegel 2011 and Luhmann`s life work in comparison to other authors mentioned during the course of this article.

O`Fallon	3.0	3.5	4.0 & 4.5	5.0
Cook-Greuter	3/4	4	4/5 & 5	5/6
Angerer	1st Phase	2nd Phase	3rd Phase	4th Phase
Pattern	Thesis	1st Negation	2nd Negation	Synthesis
	Outside as Inside	Inside-Out	Outside-In	Inside as Outside
	Pure Subject	Individual	Systems	Shared Substance
Hegel	Subjective Spirit			
	Consciousness			
	Self-Consciousness	Mind		
		Objective Spirit		
		Free Will	Subjective Will	Substantial Will
		Rights	Morality	Ethical Life
	Other for Other	Despotism	Relationality	Intersubjectivity
Parsons	Adaptation	Goal-Orientation	Integration	Pattern Maintenance
	Cognitive Mode	Evaluative Mode	Value-Orientation	
Luhmann	Communication	System-Environment	Integration	Self-Thematization
	Temporal	Factual	Social	Identity
	Incongruency	Latency	System-ness	Functionality
Kant (first Critique)	Time	Space	Self-Consciousness	
	Receptivity	Spontaneity	Intuition	
	Inherence and Subsistence (substantia et accidens)	Causality and Dependence (cause and effect)	Community (reciprocity between agent and patient)	
Kohlberg & Habermas	Conventional: Incomplete Reciprocity and Duty vs. Inclination		Post-Conventional: Complete Reciprocity and Autonomy vs. Heteronomy	
	Stage 3: Good Social Relationship	Stage 4: Maintaining the Social Order	Stage 5: Social Contract	Stage 6: Discourse Ethics
Maslow	Behaviorism	Freudianism	Humanism	Transcendence
Loevinger	Cognition	Character Development	Interpersonal Mode	Conscious Preoccupation
Aurobindo	Separate Individual			
	Mind Proper			Almost Spirit
	Externalizing Mind	Dynamic Mind	Thinking Mind	Higher Mind
Whitehead	Conceptual Origination: Adjustment of valuation	Physical Origination: Actuality but deficiency in the solidarity	Perfected Actuality: Oneness without loss of individuality	Self-completion: Each actuality included as fact of relevant experience
	Actual Entities	Eternal Objects	Substantial Activity	God
	The things to be received	The act of perception	The manner of reception	The subjective purpose
Sartre	Isolation	Reciprocity	Interpenetration	Collective Praxis
Derrida	Openness for Perception of World	Now of Consciousness facing an Object	The Present Tense of Discourse	Surface of Envisaged Presence
De Chardin	Centering everything partially upon oneself	Being able to center oneself upon oneself constantly	Being brought into association with all the other centers	Birth of some single center from the convergent beams of million centers

Preliminary Contemplations on Tier Patterns

However, for Hegel “ the subjective spirit and the objective one are [only] seen as the way through which […] the absolute spirit as reality that is equally eternal in itself as it is returning and returned Identity; the one and general substance as spiritual […] as the certitude of the objective truth” (Hegel 2011, §§553-555). It is itself not only holding together the subjective and the objective spirit, but is, too, the culmination of a trinity of layers called being, essence and notions – for many reasons we simplify here again. Notions are generalized and enduring interpretations and culminate in ideas which are truth in itself and for themselves but these notions and ideas are “still the idea in its subjectivity, and hence in its finitude in general. It is […] [their] purpose that ought to realize itself, or the absolute idea itself still in its appearance” (Hegel 2010, p. 696). The absolute idea alone is for Hegel (2010, p. 735) “being, imperishable life, self-knowing truth, and is all truth”. And that especially as it brings together the ideas and notions with being – the seriality of phenomenological appearances – as well as with essence – the moment where being becomes mediated with itself through another, the negativity of itself.

For the founder of pragmatism, Charles Sander Peirce (1998), these three layers can be called firstness, secondness and thirdness or the ideas of first “a Quality of Feeling […] [, and] of that which is such as it is as being Second to some First, regardless of anything else […] that is to say, it is Reaction as an element of the Phenomenon […] [while] the Third is the Idea of that which is such as it is as being a Third, or Medium, between a Second and its First. That is to say, it is Representation as an element of the Phenomenon” (Peirce 1998, p. 160).

For Luhmann (2018b) society or first order observations can be considered as some kind of third, or the interpretant between phenomenon, hence communication and the reactions, the differences and identities of systems. However, for Luhmann a truth as that which Hegel points to, does not exist, neither a pragmatic consensus as Peirce thinks of, when he points to his categories. While the first order observer ends with notions, “statements about invariant foundations, about nature and necessities […] [, while for the second order observer] anything that the first order observer observes […] depends on the distinctions which where underlying the observations; and it always can be different distinctions” (Luhmann 2018b, p. 1121f). There is a contingency for the second order observer, which it, contrary to the first order observer, can choose where it creates latency and blind spots and thus to it “the world appears as constructions based upon different distinctions” (ibid. 1122).

Though, for Luhmann no truth exists but anything, whether called subjective or objective, accidental or substantial, truth or lie, actual or possible, is contingent, the reduction of an incomprehensible complexity, “which increases the probability of the desired and decreases the probability of the undesired” (Luhmann 2016b, S.98f), anything can be marked as true through observation: “the management of differences” (Luhmann 2012, p. 63). Despite that old conflict – which we already mentioned into the introductory paragraphs of this article, between structure and genesis, patterns and differences, substances and accidentals, insides and outsides, the possibility for truth and construction reaching from the inception of time to these great thinkers, we are now up to explore Luhmann`s path into the realm of second order observations – by this we will point to some important differences between both views, or as Wilber (2018, p. 681) puts it: each holon “can be looked at from ‘without,’ or from the ‘outside’ in an objective/universal/rational stance, or looked at from ‘within,’ or from the ‘inside’ in a subjective/local/cognitive/enacted stance” – and we attempt to do both for better comprehension.

In the succeeding section, Luhmann`s writings after 1980 can be classed at least into two stages each completing a circle of four grammatical phases above the Construct-Aware: a) where ideas are primarily concerned about the way differences and unities are created through observation and later b) how observations deal with paradox to create cognitive, subjective and constructed internal identity. In the following paragraphs we will no longer point too much to grammatical markers. We will restrict ourselves to mentioning the phase wherein the textual examples could best be put and how the conscious preoccupation, interpersonal mode and identity-formation evolve and change with the distinguishable semantics. Respectively sections are no longer translated with the same grammatical accuracy but towards optimizing the reading flow. Additionally, to locate the tier sequence from being, to essence, to notions and absolute spirit or from firstness, to secondness, to thirdness and beyond into Luhmann`s realm of second order observations within a broader reality we reference not only other thinkers seemingly from these stages but some concepts from earlier stages, too. As thorough these classifications are as thorough should be the caution when reading these assessments, as no one is free of stepping into misjudgment, e.g. for reasons of transference.

Construct-Aware and Unitive

The Early 1980s: Entering Unitive

As we have seen, the move into the integrative phase of Luhmann`s writing was signified by a loosening of the boundaries created by the subordinating mechanisms and the latency or displacement and repression mechanisms of a system out of subsystems which marked the exiting phase of the Achiever stage. The boundaries are loosening their hierarchical mode and "drawing of boundaries does not necessarily mean less communication, in general even rather an increase, as the passage is specified and thus eased up" (Luhmann 1966a, p. 85) – communication channels become clear and therefore accessible. However, this interplay of subject and object takes on different forms and is further increasing in 1970. The interaction of inside and outside there could for example mean that systems can "reach 'ultrastability'. They can stabilize internal boundaries between sub-systems in the meaning of thresholds, which restrict a transmission of effects – […] therein lies a substantial speeding up of intra-systemic adaptative processes, an important temporal gain for survival. This initially enables the emergence and maintenance of higher order systems. […] in a more complex world" (Luhmann 2018c, p. 159f). And thus, there is a deep relationship between two sides of reality: the completely inside and the completely outside in their combination as unity. Or as Alfred North Whitehead (1978, p. 148) says "every item of the universe, […] is a constituent in the constitution of any one actual entity" or of any particle, life-form or system of any kind. For him, too, this completion of inside and outside or rather anyone and anyone else is part of a four-phased process wherein "the creative action completes itself [in the fourth phase] […] for the kingdom of heaven is with us today […] [, which] is the love of God for the world" (Whitehead 1978, p. 354).

It is exactly ten years later when Luhmann starts with *Societal Structure and Semantics* both a new series of books and the next nominal or adaptative phase. Here, we still cannot see the term of observation substituting self-thematization, but a new degree of complexity when it comes to his recognition of the "others as other", of first to second person interactions: "the differentiated states [here] are not in relation to each other, but historically in relation to the earlier state functionally equivalent. Exactly that allows the substitution in direction to functional differentiation; it is functional substitution of functionally for each other no longer substitutable states. The differentiated states then align by this that they can only jointly substitute an earlier one, on whom they themselves depend" (Luhmann 1993, p. 169f).

What we can see here is that the nominal function takes on different means: it is the switching between antonyms or the expression of two parts formulated in opposition but union, a sentence of adversaries in an instance – inclusion of others as other means therefore "[Rhema 1 Fully differentiated behavioral complexity has to be introduced into society again] [Rhema 2 stating the opposite and by this has to be made compatible with these behavioral competencies, against which they have been differentiated]" (ibid. p. 170). Or as Jacques Derrida (2007) writes, this phase deals in a paradoxical fashion with the *Inventions of the Other* "the other is indeed what is not inventible, and is therefore the only invention of the world, our invention, the invention that invents us" (Derrida 2007, p. 45). As Jean Piaget (1956, p. 246) points out "reciprocity is the fundamental relation which one finds within each totality" and here the adaptation starts with a whole new kind of it, leading to new and "more complex relationships of inclusion, interference, negation, etc." (ibid. p. 236) that are in themselves and by their nature antonymic.

This structure thus looks like the fourth phase moved into an extreme. Additionally, it shows up on the surface of Susanne Cook-Greuter`s Unitive stage, too. Hence, being with other people can in the more accusative to dative phase mean that it "[Rhema 1 is not necessarily dependent on proximity (distance) – or time for that matter.] [homonymic hyponymic theme One could be next to someone and not 'be with them'.] [homonymic synonymic rhema 2 'Being with' seems more like realizing that an 'other' is somehow part of 'you',] [homonymic rhema 2 as antinomy and 'you' are part of 'them' – if only for a moment]" (Cook-Greuter 2010, p. 80) and the dative to instrumental phase brings forth a feeling of feeling sorry "[Rhema 1 as antinomies for everyone and for no one –] [equation-like preceding rhema 1 all of us suffer, and much of it is self-created...] [rhema 1 antonymic part yet none of us is ever really in danger at the level of the Absolute] [rhema 1 beneficiary applicative as ablative and there is potential good that can come from whatever we are experiencing right now]" (Cook-Greuter 2011, p. 16).

Not only in these sentence completions we can see the arising of a new "I = I" in the Hegelian sense, where the subject is merely the same as the object but Luhmann, too, says "that through present communication the pasts and the futures of other persons […] can be made present. As different persons provoke each other's actions reciprocally, the temporal horizons of simultaneous or quasi simultaneous events melt together. The temporal horizons or action events become relieved from the sequentialization through one continuity of consciousness. They, only that way, gain the form of a horizon that can be supposed as intersubjectively-common. The time becomes separable from events, on which meanings it arises, and wins the form of a (culturally interpretable) world-dimension" (Luhmann 1991, p. 257f) or as Hegel would put it: a place "where the spirit […] [as a history] becomes, too, for itself a general of the external, becomes the world spirit" (Hegel 2011, §549). But, Luhmann in this essay on *Temporalization of Complexity* still displays a large number of markers pointing towards a fourth phase of the earlier – as shown Construct-Aware – stage of his writing.

Luhmann sometimes not experiences permanently or – as Terri O`Fallon (2010, p. 19) might write: "rocks back and forth" – points towards this experience of a shared conscious world-dimension, with a presence or independence from one single, isolated experience of time. It is a sort of prophecy of a new sphere or as he puts it: "[rhema 1 as thesis A further differentiation of events […] never ends with a new, perhaps timeless dimension of elements,] [rhema 2 as antinomy even though one has to confess to the mystics, that the infinity of progress into the small matches the infinity of the progress into the large] [rhema 3 as synthesis and one insofar can find eternity in each moment]" (ibid. p. 244).

This idea of touching into a new dimension of freedom can, too, show up in Construct-Aware sentence completions: a good boss for example "[rhema 1 thesis is able to unleash the potential and abilities of staff] [rhema 2 as comitative and instrumental applicative by creating a situation in which they choose willingly to live of their best, having a clear understanding of goals, roles and their unique combination,] [rhema 3 as synthesizing context pointing to something "unknown" as within a supportive, challenging and ultimately liberating environment]" (Miniard 2002, p. 72) and is typical for Hegel's *Phenomenology of Spirit*, too. There, in certain moments, absolute spirit shows up, for example in a moment of forgiveness, where "[rhema 1 the word of reconciliation is the objectively existent Spirit,] [rhema 2 as comitative with antinomy which beholds the pure knowledge of itself qua universal essence, in its opposite, in the pure knowledge of itself qua absolutely self-contained and exclusive individuality –] [rhema 3 as synthesis a reciprocal recognition which is absolute Spirit]" (Hegel 1977, p. 408).

For Hegel in his, let`s name it, "late Construct-Aware writing" anything is full of meaning, both, good and evil "[rhema 1 as synthesis are purified into the unity in which there is no longer in them any existence devoid of self, any negative of consciousness,] [rhema 2 as pole one where on the contrary, duty is the unchanging identical character of its self-knowledge,] [rhema 3 as pole two and evil equally has its purpose in its being-within-itself, and its actuality in its utterance]" (ibid. p. 408) and thus synthetize each other in their mutually defining, restricting and contrary existence as a self-conscious relationship. This structure of Hegel`s philosophy of religion, where a home or place for both sides of the reality-coin exists, is analytically pointed to in Luhmann`s 1977 *The function of Religion*, where the grammar of the fourth phase still exists in isolation from that of a later phase and process of adaptation. There a functional definition of religion is about "trying to avoid the abstract one-sidedness of a single function-statement, which allows too much and renders not enough, to correct them and to complicate them through means of systems-theoretical analysis, in other words in order to incorporate in the theory of religion, that any social System, therefore society, too, has to solve more than one problem, hence, has to fulfill a multiplicity of functions" (Luhmann 1999, p. 84).

Another philosopher of dialectics, the French existentialist Jean Paul Sartre (2004) in his *Critique of Dialectical Reason* can be situated here, too, again he shows the prophetic structure, when he asks whether it is "some 'collective consciousness', a totality irreducible to its parts, [which] imposes itself externally on each and every consciousness, as the Kantian categories impose themselves on the multiplicity of sensations" (Sartre 2004, p. 391). A "collective consciousness arising from the synthetic unification" (ibid. p. 294) of a series of four, where the collective praxis leads to individuals realizing "in and through themselves the interpenetration of a multiplicity of unorganized individuals within them and that they produce every individual in them in the indistinction of a totality" (ibid. p. 253) on the basis of the two earlier forms: individuation or isolation and reciprocity. Just two years later, in the same way as Luhmann`s grammar changed, we can see Sartre`s reappropriation of the Unitive stage deep structure in his own lexis and autobiographical writing *The Words* where he for example writes about discovering his self as other: "[Thema Looming up out of an antediluvian world just when I was escaping from Nature and at last becoming myself,] [Antonymic rhema that Other whom I was aspiring to be in the eyes of others, I faced my Destiny and recognized it: it was only my freedom.] [Thema It had been set up before me by my own efforts] [Antonymic rhema as if it were a foreign power]" (Sartre p. 171).

Following Derrida (1981) in *Dissemination* where he, too, deals with the appearance of something still exterior to one`s interiority, one can say that in this fourth phase of the construct aware "discourses spring up regularly, engendered in the course of sequences that are themselves part of the quadrature [quadruplicity] of the text, belonging precisely to one of the four faces, the one that seems to be open for the perception of the spectacle [or adaptation], for the "now" of consciousness faced with its object [or goal-orientation], for the present tense of discourse [or integration] – belonging, in a word, to the face as what one faces, a surface of envisaged presence [or self-thematization]. This face also contemplates itself as the originary, immediate, unconditioned opening of appearing but it explains itself as an apparent opening, a conditioned product, a surface effect" (Derrida 1981, p. 299) before some years later – as mentioned earlier – the paradoxical grammar in Derrida`s writing takes over this appearance he in *Dissemination* calls "illusion". It now becomes part of deconstruction a process which "involves an affirmation, this latter being linked to the coming – the venire – in event, advent and invention" (Derrida 2007, p. 23), it now becomes unconditioned and beyond being just a surface some "aspect of invention, of inventive power: as if it were necessary […] to reinvent the future" (ibid. p. 23). This move from recognizing a larger mind beyond the higher mind. While in the higher mind it is still the persons "separate mental self which it makes the judge, witness and center of the universe and through it alone strives to arrive at its own higher self and reality" (Aurobindo 2005, p. 181), in this transition "the veil is rent and the divided mind overpowered, silent and passive to a supramental action that mind itself gets back to the Truth of things" (ibid. p. 181).

Further Differentiation in the Unitive Realms

Now, we have shortly expressed the move from synthesis of mutuality and two sides of reality and how the early Unitive phase shows an antonymic structure in its absolute. However, towards the fourth phase of the first Unitive cycle and Luhmannian life-stage two things happen: a) first, the antonymic structure gets framed as paradox, a word that increases in number, importance and scope of meaning from the 1984 *Social Systems* towards the books about economy, politics, moral, religion, education and other subsystems of society where paradox is mentioned more than a hundred times within each book and b) the typical triadic structure which was present in all of the four earlier stages from Achiever, to Pluralist and Autonomous towards Construct-Aware moves into a quadruplicate form or a more symmetric style of writing that reminds of that which is present in concrete operational writings like in this passage from the Hymns of Homer: "[Rhema 1 part one And so long as she, the goddess, yet beheld earth and starry heaven and the strong-flowing sea where fishes shoal, and the rays of the sun,] [rhema 1 part two and still hoped to see her dear mother and the tribes of the eternal gods,] [rhema 2 part one so long hope calmed her great heart for all her trouble] [rhema 2 part two and the heights of the mountains and the depths of the sea rang with her immortal voice]" (Hymns II, 33-39).

This parallel structure can be apprehended in the 1986 *Ecological Communication*. Here the first cycle of observation is completed and Luhmann, in defense and in an attempt to sustain the system of ecological communication, writes "[rhema 1 part one overall it is obvious that with the scientific inquiry the respect regarding 'natural equilibria' has grown,] [rhema 1 part two be it within ecological interrelationships, be it within different countries and today even in developing countries,] [antonymic part of rhema 1 part one that however, at the same time the own society is exposed to the most enormous critique] [antonymic rhema 1 part two and exaggerated with calls for intervention, as if it were no longer a system]" (Luhmann 1990, p. 20). This sentence is both a) a more extreme formulation of the first phase variation of antonymic construction and b) including much of instrumental and locative modifications and contrasts of a fourth phase and contains this in the quadruplicity of this nominal and homonymic antonymic superstructure. This kind of structure – including four meaning carrying clauses not just reformulations or explications – is something one can, too, see in some of the Unitive sentence completions where this fourfold dissection can take on form as in I am "[rhema 1 someone and everyone,] [rhema part two special and ordinary,] [rhema 2 part one one tiny part of fast cosmic system] [rhema 2 antonymic part two who has the potential to make a difference]" (Cook-Greuter 2010, p. 82) including two rhema in a, nominative to accusative phrase similar to what we have seen in Achiever sentence completions and which might show up here more in direction of a dative-like phase e.g. a good boss "[rhema 1 of goal orientation is someone who knows how to balance authority and freedom,] [rhema 1 part two who is able to embody and/or give voice to the deeper mission of the organization,] [rhema 2 part one of adaptation while seeing it in the context of society,] [rhema 2 part two and can do this in service of a deeper Reality]" (Miniard 2002, p. 75). It even can show up with one rhema like in a good boss "[rhema 1 part one can be a 'boss'] [rhema 1 part two if he needs to,] [rhema 1 part three or a coach, leader, shaman,] [rhema 1 part four antinomy or disappear]" (Miniard 2002, p. 74).

So, now, as we have looked at the seemingly new superstructure, lets come to the paradox: Luhmann in 1984 formulates one of the paradoxes, a paradox that says that a system can only comprehend its rationality from understanding its subsystems and which "we attribute to the pure form of self-referentiality, and we therefore see the rationality as re-entry of the difference into the different, as installation of an open system/environment-difference into the system that identifies itself through this difference" (Luhmann 2012, p. 641). The paradoxes here are concerned to move the system and its self-referentiality from anti-passive and being a receiver in an involuntary sense of a voluntary, integrated beneficiary towards agent-oriented-intransivity to create a "system which disposes over its environment, [as it then] basically disposes over itself" (ibid. p. 641).

This idea moves into observations of observations about the possibility of dissolving antinomy or the so-called paradoxes. Again, this is, similar to the first Unitive phase, a special and emergent kind of dealing with subject and object. It now generates and is characterized in *The Economy of Society* through the "possibility for observing observers. As the observational context varies from observation to observation, one can only comprehend such a system as polycontextural system; and our thesis is, that the system for this has to take on the form of an environment for participants, of an environment, which does not variate randomly, but is neither a simple function of purpose-oriented behavior" (Luhmann 2019b, p. 98). Luhmann manages this switch after an intermediate fourth phase. However, in this intermediate phase one first has in fact "to reverse into its opposite the general perception that first a 'subject' has to make an aware decision for communication and then it can act communicatively. First if out of reasons [from systems], which cannot be ascribed to a consciousness, ecological communication can get under way and start to co-determine societal communication, one can expect that the topics of this communications gradually become contents within consciousness" (Luhmann 1990, p. 65). This switch, where the "inside" or "goal-orientation" of systems determines their environment as conscious subjects and thus themselves, generates a surrounding or environment which is no longer co-subordinate but strictly subordinate, in the sense, that one can achieve new orders of complexity through shifting the boundary and redefining something not as system but an environment – the whole earlier problem ends in smoke as mental and thus communicative or discoursive boundaries become acts of a second order observer, observing its needs. This finally enables to resolve paradoxes through "imposing a difference of level or a hierarchy" (ibid. 2019b, p. 99). Therefore, for example the paradox of scarcity – "that each access to scarce resources, which serves the reduction of scarcity, increases scarcity. Increasing supply of one is larger hardship for others, and only because it is that way, the social problem of scarcity exists" (ibid. 2019b, p. 98) – can be resolved through different options, e.g. if society "establishes indifference to the misfortune of others, that is, to grant the full differentiation of the economic system" (ibid. p. 99) or through making the paradox invisible relocating it to "the invisible hand" (ibid. p. 99).

Differently said, Luhmann points out the interplay of two antinomies creating a certain state and looks how this paradox shifts from level to level through creating different observations and scripts within the environment – or as he in the third and dative state of this phase formulates “each paradox is only paradoxical for an observer who has already systematized his observations. […] And a path laid down on behalf of resolving can be described as the re-entry of the form into the form or of the distinguished into the distinct. As the form within the form is at the same time not the form, it is a paradox but likewise an unfolded paradox; as one now can choose distinctions, whose re-entry can be interpreted. An observer has the double-option to describe a system both from the inside and the outside, hence to choose both an internal and an external point of view. It is self-evident that he cannot do both simultaneously as he therefore has to use the inside/outside distinction” (Luhmann 2018a, p. 179f). Hence, we are here in a new period of system and environment differences, though anything that happens is within the oneness or unity of within the system creating distinctions and differences by and upon itself.

Luhmann in this phase does approximately match up with Ken Wilber`s (2000) *Sex, Ecology and Spirituality* however Luhmann`s four quadrants are as mentioned the temporal evolution, the factual differentiation and the social communication connected through the autopoiesis of society, the self-thematization and self-description of itself as “different entering gates for the depiction of the total painting” (Luhmann 2018b, p. 1138) of a theory of society. But while for Wilber the fifth dimension added with the new tier or the basic operation is: “No objects, no subjects, only this. No entering this state, no leaving it; it is absolutely and eternally and always already the case: the simple feeling of being, the basic and simple immediacy of any and all states, prior to the four quadrants, prior to the split between inside and outside, prior to seer and seen, prior to the rise of worlds, ever-present as pure Presence, the simple feeling of being: empty awareness as the opening or clearing in which all worlds arise, ceaselessly: I-I is the box the universe comes in” (Wilber 2000, p. 318), Luhmann introduces in his Unitive writing the difference of medium and form. Both, however are no real existents or reals, like the timeless witness, but artificial distinctions in which “the system operates in a way that it binds its own medium towards its form, without dissipating the medium by this, as much as light is cannot be wasted through seeing. […] Ultimately one here needs to observe that it is not the medial substratum, rather the form which is operatively compatible in the system. […] One does not see the light, but the objects, and when one sees light, then on the surface of objects. One does not hear the air but sounds; and the air itself has to make a sound if it wants to be heard” (Luhmann 2018a, p. 194ff). And the basic medium generating self-descriptions and observations is communication “which makes the unlikely nevertheless likely: the autopoiesis of the communicative system of society” (ibid. p. 197). However, for Luhmann many media exist, but these of society all are grounded on speech, language and communication – the opening or clearing in which all words arise – and which later artificially differentiate between this oneness where media can become form like “light that becomes allowed in cathedrals, becomes form, to play with the pillars and arches. The physical structure of the world has to enable this, but the differentiation between media and form is a personal contribution of the observing organism” (ibdi. p. 197).

This again reminds us of the *Formal Organization* where Luhmann reduces the social function of his systems-theory to the “generalization of behavioral expectations, which express themselves in the possibility of implying a consent regarding the formal expectations with all members regardless of their individual, different preferences” (Luhmann 1964, p. 68) – but now there are no longer shared opinions, one subordinates, but both inside and outside, and the four dimensions of society arise all through the surface of media.

From Second to Fourth Phases

Whereas in the movement of the third and fourth quarter the social dimension of second order observations increases, in the first quarter new and more paradoxes arise. The resolution of the paradox of scarcity disembogues therefore again in a more elaborate version of the 1984 paradox of self-reference and differentiation within this self-reference: "The system as unity and the system as difference, namely as difference of an each time participating system and its system-internal environment" (ibid. p. 101). Respectively, this differentiation between two levels of a system, as difference and unity, was not given in 1984, when Luhmann finished his *Social Systems*: there it is only the difference "which virtually holds together the different; it is different, and not indifferent. Thus far, as differentiation is brought onto a uniform principle, one can read the unity of a system from its differentiation. The system gains systematicity through differentiation, it gains additionally to its pure identity (in difference to others) a double-container of its unity (in difference to itself)" (Luhmann 2012, p. 38).

In the same sense as there does not exist a second order observer in 1984, the writing is more about the way this difference creates unities – not the possibility of shifting between two sides – of "both… and" like inside and outside, system and environment, process and structure, elements and relations, order and chaos and so forth reminding of verse 2 of the Dao de Ching where it is said that "if man know the beauty, they, too, understand what is ugly. If they learn what is good, they, too, realize what is evil. In this way being and not-being, heavy and light, long and short, high and deep, allow to know each other". However, we have to point to the slight difference, or as Luhmann in 1984 would say: "One has to notice the dialectics" – "One approaches dialectics, when one in light of the synchronization of self-reference and other-reference is interested in the underlying unity. Hence, ultimately turns towards the unity of unity and difference and not towards the difference of identity and difference" (Luhmann 2012, p. 607). As we have already shown: the Unitive stages have four operations in their repertoire instead of three as the earlier stages – as we will point out in *4.b Alternative Tier-Structure* – from Expert to Construct-Aware and hence the old notion of the Buddha, which says "between perception and action lies interpretation" has to be reformulated in a certain sense into: beyond the oneness of perception and action through interpretation lies awareness of interpretation, or the absolute idea and spirit. Figure 5 depicts this difference between the two tiers.

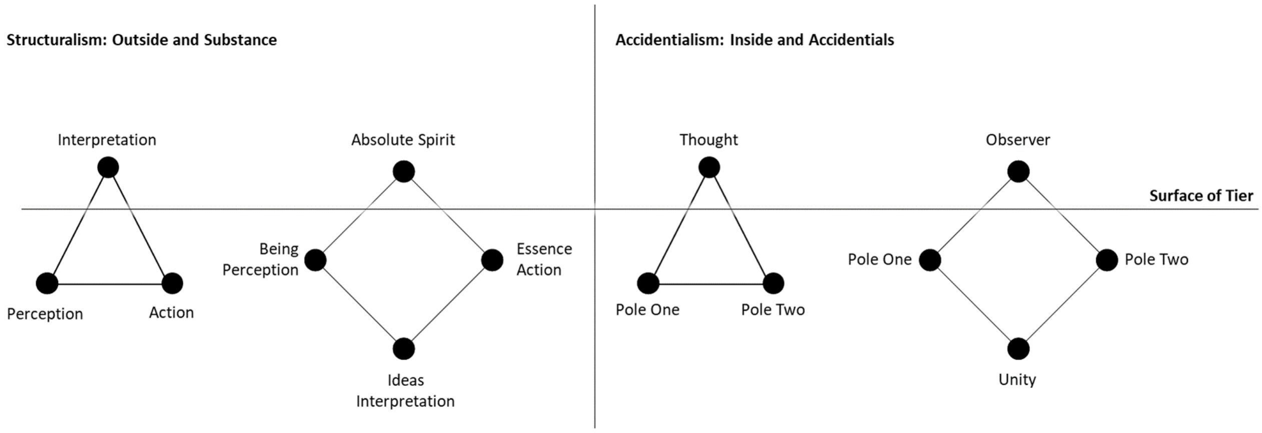

Figure 5. The difference of the "both… and" periods of adaptative stages in two tiers and their more structuralist, outside and their more genetic, inside expressions.

One can show this within Ervin Laszlo's (2002) *Systems View of the World*, where not paradoxes are unfolded but the quadruplicate structure always consists out of 1) awareness of 2) something that could be classified as interpretation 3) something that could be classified as essence and finally 4) something that relates to being. For example, when he writes about the systems-view of oneself he differentiates three layer of sub-organic, organic and supra-organic which are "rather 'levels' rather than 'categories' of reality, distinguished in reference to modes of organization rather than to essence or substance" (Laszlo 2002, p. 27) which are reiterated and explored either in sentences or in paragraphs: "[Supra-organic the human being is a module] [Organic in the multilevel structure that arose on earth as a result of] [Sub-Organic part 1 as awareness of pole one nature`s penchant for building up in one place] [Sub-Organic part 2 as awareness of antonymic pole two what it takes down in another]" (Laszlo 2002, p. 60).

However, as one might think of Teilhard de Chardin and others, these three layers exist earlier, too, but what is different is there is no simultaneous view from within all three of these levels plus awareness but one broad view projected onto them – onto merely one at a time as syntheses of the sentence, as the interpretation between action and perception: for example when de Chardin writes that "really, love-that is to say, the affinity of being with being-is not peculiar to man. [Theme as Synthesis It is a general property of all life] [Rhema part 1 as Action and as such it embraces, in its varieties and degrees,] [Rhema part 2 as Perception/Adaptation as all the forms successively adopted by organized matter" (de Chardin, p. 264). Not only is there intense anthropocentrism in the notion that "by rights, to be certain of its presence in ourselves, we should assume its presence, at least in an inchoate form, in everything that is" (ibid. p. 264) but, too, lacks the "unfoldment of paradox" that is there in more structuralist writers, too, even if backgrounded and in a more classifying manner of sorting into categories of levels. Therefore, for Laszlo "the fact that physical entities such as atoms provide communication between their parts in terms of the interaction of field or force potentials, that things such as organisms provide parts communication by physicochemical means, and that multi-person organizations stablish communication of quite another kind, does not invalidate their wholistic character" (Laszlo 2002, p. 29). Here communication as partiality and wholeness are unfolded into one communication based on separation "constitutes an integrated unity of all these in mutual relation" (ibid. p. 28). And the many forms communication can take here are nothing "but in all it forms what remains communication" (ibid. p. 29), sorted into a fourth category or structure of awareness.

One can see this in Wilber`s (2000) *Sex, Ecology, Spirituality*, too, anything is "nothing but within a quadrant" and each quadrant is in itself a triplicity of levels, as we can see here for the Upper Left – the interior Quadrant of the Individual: "[Fourth as Awareness When it comes to the developed forms of depth in humans,] [Third as Interpretation I only have access to that depth via interpreting] [Second as Action what you tell me] [First as foundation for perception in a dialogue]" (Wilber 2000, p. 141). Understanding self and other becomes a fourfold process as Wilber shows in this illustration: "[Rhema 1 And thus, I have to reread the text of my own feelings], [Rhema 2 locate the source of my insincerity,] [Rhema 3 and reinterpret my own depth more faithfully,] [Rhema 4 as providing Awareness with the help, usually, of somebody who has seen the mistranslation before and can help interpret me to myself.] The issues are meaning, interpretation, and sincerity (or its lack)" (ibid. p. 142).

This shows up in Unitive sentence completions, too, e.g. in "I feel sorry… [Expressing awareness for many things, and grateful also,] [Interpretation Layer: Expressing interpretative Ambiguity as these same things have often pulled me beyond the "small self" need to apologize] [Being Layer: Expressing Perception towards recognition of] [Essence Layer: Expressing ground for Action much greater ground for learning and living]" (Cook-Greuter 2011, p. 17) versus the completions with two poles depicted earlier.

Especially, when Luhmann looks at the social system in this phase, he describes it as a receiver, as said, a beneficiary in receipt of its constituting elements, words, which turn into communication, and come from conscious systems or humans: “With the distinction of system and environment it is gained the possibility to understand the human as part of the societal environment at the same time as more complex and unbound, as it were possible if he had to be construed as part of society; because environment is, in comparison to the system, precisely that area of the distinction which displays higher complexity and less being-structured” (Luhmann 2012, p. 289). However, this also means – before moving into the fourth phase as described above – to turn the point of view and see humans as those who benefit from society and society as some sort of external possessor or dativus judicantis, judging the utility of humans for the viability of systems, and so, humans “can only develop their complexity in regard to the social system and are at the same time used by the social system […] to extract actions from them, which are supportive of the requirements of social combinatorics” (ibid. p. 293). However, as we have seen in the third period of Achiever and within the Autonomous writing, there is a great amount of “depending on” and “according to” thinking – the animate environment thus is possessed but only “with different selectivity and different compatibility and different backgrounds and futures” (ibid. p. 293).

Luhmann here in 1984 answered a question he asked in 1981: “How is social order possible on the basis of plural subjectivity of synthetizing performances” (Luhmann 1993, p. 253).

A question that has been slightly differently stated by one of the founding fathers of German sociology, namely Georg Simmel (2018), who beautifully answered it in a third phase unfolding of paradox between a transcendent and an immanent of a second order observer: “Societies are buildings out of beings which can stand on both sides inside and outside of it […] by which society creates maybe the most conscious, at least the most general expression of an archetypical form of life: that the individual soul can never stand within a relationship, on whose outside it stands at the same time, that it is never put into an order, whose outside it is, too. […] The religious man feels completely embraced by the divine being, as if it were just a pulsation of the life divine, its own substance is unreservedly, even in mystical undifferentiated-ness given into the absolute. However, to give this being-molten-into any meaning after all, it has somehow to sustain its separateness […]. The oneness is in its meaning dependent on the other-ness of god” (Simmel 2018, p. 53).

However, for Luhmann humans are not that important in answering the question of how society is possible in 1984. Speech is one constituting moment humans add and by which they are integrated with the social system, while the social system is reciprocating with them, but central are the ideas of observation and autopoiesis, or to apply “the terminology of observation and self-observation on the level of a general systems-theory, and […] combine it with the idea of autopoiesis, self-observation becomes a necessary component of autopoietic reproduction” (Luhmann 2012, p. 64).

This mode of observation and autopoiesis slowly starts to grow into place in the 1980s. In his book *Political Theory and the Welfare-State* Luhmann (2011, p. 51) says that “self-observation would have to include the observing systems and lead them to self-reflection”. However, here this mode is rather “the continuation and augmentation of generalizing judgment” (ibid. p. 52), which is in Luhmann`s last book within this seeming stage recognized as an “observer that recognizes that its object is a self-referential system, and recognizes with this additionally that this object is constituted tautologically and paradoxically, and in so far randomly and without the possibility to operate, which means it cannot be observed. […] It recognizes its own paradox: the arbitrariness and impossibility of an observation" (Luhmann 1990, p. 55).

However, earlier in the 1980s exactly this arbitrariness first allows to see system and environment as "relationship between interdependencies" (Luhmann 2011, p. 53) and then in the difference of system and environment which creates, through shifting of boundaries, "the evolutionary surplus of the achievement of 'meaning' on the basis of an no longer stoppable self-referentiality of systems-constitution: a meaning that lies within an unprecedented combination of closedness and openness towards the environment of systems-structure" (Luhmann 2012, p. 64).

Luhmann in 1984 basically talks about time, i.e. autopoiesis as self-constitution and self-reference in differentiation that sustains systems as long as they don't lose "their determinability, hence their compatibility for further operations" (ibid. p. 59) and meaning is created by an observer through creating differences "as a surplus of references towards other possibilities" (ibid. p. 95) and therefore he primarily depicts a temporal movement. Contrary meaning in 1975 is based on reflections on time – evolution – but not anything is contained within time. Rather meaning is, when he back then touches from the accusative into the third and dative phase, where "the simultaneous presence of each actuality and horizon imparts meaning to the given, more functionally expressed: concrete access to and localization within other possibilities. Whatever 'underlies' meaning: meaning covers anything that is pregiven to it, with appresentated references, which radically transform the actuality and leaves nothing meaningless. The permanent fabrication of this 'co-presence' within the daily lives, […] enables and enforces likewise foremost effective procedures of selection – namely those, which co-present and keep present for further operations the 'wherefrom' or 'from whom' of selectivity" (Luhmann 2017a, p. 633). Differently put it is dependent on a place wherein and not only pre-given, but additionally not aware of being a process coordinated by an observer, but rather based on the experience of reality and the experience of boundaries which allow "to thematize across borders the environment after the system or vice versa: the system after the environment" (ibid. p. 638). Here in 1975 Luhmann again reminds strongly of Whitehead, who writes in an almost perfectly matching grammatical phase, that "the subjective form originates, and carries into the feeling [, into presence,] its own history transformed into the way in which the feeling feels. The way in which the feeling feels expresses how the feeling came into being. It expresses the purpose which urged it forward, and the obstacles which it encountered, and the indeterminations which were dissolved by the originative decisions of the subject" (Whitehead 1978, p. 232).

What we have already pointed to, using *Process and Reality*, is the synthesis of opposites "in the final unity of one actual entity [which] is another fact of 'givenness.' The actual entity terminates its becoming in one complex feeling involving a completely determinate bond with every item in the universe, the bond being either a positive or a negative prehension" (Whitehead 1978, p. 44). And in the same way Luhmann can in this Construct-Aware stage – as he further grows into the third phase – comprehend, as two sides of a coin, that "contrary to appearance, binary schematizations don`t serve the division rather the conjunction of opposites. They ease-up the transition of one definition of a situation towards its opposite, by demanding nothing more than a negation, whose admission is regulated in the system – a technique of paradoxical integration" (Luhmann 2013, p. 41). This is a first glimmer or the substratum and contained object of what dawns to him in his book about *Social Systems*, namely as differences created by an observer – differences that are both something that makes a difference and autopoietic structures and processes of system and environment, which co-evolve in mutuality, producing differences in a way they become or are perceived as a unity.

Contrary to this recognition of the "both… and…" structure within the third phase of Construct-Aware or the self-thematizing stage, the second phase deals much with modes of thinking as did the second phase of the integrative period in Luhmann`s writing in the mid-1960s. However, while the pluralist mode was directed towards e.g. "information processing through communicative action as it is the precondition of all higher forms, to apprehend and react adequately to all complex environmental interdependencies" (Luhmann 1966b, p. 69), and thus there was only one point of view, that of a third which nevertheless apprehended other in a way that could lead to a functional fit, the self-thematizing Luhmann looks at both sides simultaneously – at system and environment – and how they could as one whole, or one communicative intersubjectivity stabilize certain self-narrations and thus self-maintenances. One can see this for example in the 1972 *Political Planning* where Luhmann writes that "meaningful behavior in systems of communication of public opinion requires the reduction of high complexity, requires especially an overcoming of the barrier of experiencing-and-being-able-to-act-differently-too of others and thus becomes demanding and difficult, as therefore the recruitment into the system itself – and that always means, too: more or less imperceptible socialization within the system – has to be requested" (Luhmann 2007, p. 26). One can see these thoughts, too, in Pierre Bourdieu's (2016) *Distinction*, if slightly differently oriented, but "the contentions for the acquisition of cultural goods at the same time represent symbolical contentions for theses distinctive features […] [wherein] the value of culture constitutes itself or, which is in the end the self, as the belief of the value of a culture, the interest in and what is interesting about culture" (Bourdieu 2016, p. 388f). As Luhmann puts it "the full differentiation of sub-systems should not mean that the causal or communicative interplay of these sub-systems with their respective societal environment are cancelled or are comparatively minimized […] [but] based on the recognition and minding of the rules on whose basis communication creates selective accomplishments and helps to allocate, as part of a system, through the kind and the direction of a selection" (Luhmann 2007, p. 27). And these selective mechanisms are reflected by Bourdieu (2016, p. 389) – the "basis of this dynamic of the field, wherein the cultural goods are produced, reproduced and create profit of distinctions through their circulation, which are the strategies that especially through their reciprocal competitiveness lead to these objective outcomes, contribute to the scarcity and the belief into the value of these goods" and regulate the affiliation to a social class, which is a system.

Completely contrary to regulating the integration into system Wilber (1996) writes in *the Atman Project* using a similar grammatical overlay of the Construct-Aware stage how transcendence works through dissolution of boundaries, because „the subject can find the prior Whole only by letting go of the boundary between subject and object—that is, by dying to the exclusive subject. And the subject, obviously, is terrified of this. And because he can't or won't let go of and die to his separate self, he cannot find true and real transcendence, he cannot find that larger fulfillment as the Whole. Holding on to himself, his subjectivity, he shuts out Atman; grasping only his own ego, he denies the rest of the All" (Wilber 1996, p. 119) – it is basically the condemnation of the earlier depicted Construct-Aware view the more Aristotelian thinker generate, where there still exists a "real" or "projected" inside and outside, which are in relationship and where boundaries are regulated before at the next stage one embraces a "both… and… and the relationship of both sides to each other". So, where for Luhmann the line stays important up into the Unitive realm within his *Theory of Social Systems* for the neoplatonic Wilber "to erect a self-boundary or barrier and hold a separate-identity feeling against the prior Wholeness, not only involves illusion, it requires a constant expenditure of energy, a perpetual contracting or restricting activity" (ibid. p. 119) at the Construct-Aware level.

This view matures from his *No Boundary* in the more nominative phase, where the drawing of a line can be shifted in radical ways and where "the most radical re-mapping or shifting of the boundary line occurs in experiences of the supreme identity, for here the person expands her self-identity boundary to include the entire universe. We might even say that she loses the boundary line altogether, for when she is identified with the 'one harmonious whole' there is no longer any outside or inside, and so nowhere to draw the line" (Wilber 2001, p. 5).

While Wilber here says "what you are actually doing, whether you know it or not, is drawing a mental line or boundary across the whole field of your experience, and everything on the inside of that boundary you are feeling or calling your 'self'" (ibid. p. 4), and negates the very act of creating boundaries as contrary to the ultimate he, in a 1984 essay on the *Spectrum of Psychotherapy* writes in respect to human maturation: "Healthy or normal negation serves several important functions. Horizontally, it helps differentiate self and object representations; vertically, it helps the disidentification, differentiation, separation, or transcendence of a lower level in favor of a higher" (Wilber 1984, p. 86). One can see this tendency of outside views to be concerned about this negation in Hegel (1977, p. 12f), too, where he writes that "it is the coming-to-be of itself, the circle that presupposes its end as its goal and has its end for its beginning, and which is actual only through this accomplishment and its end".

For Wilber (1996, p. 194) in *the Atman Project* unity is the sole purpose of man and "in place of unity consciousness, the individual, on the one side, takes as substitute self an inward-subjective world, and, on the other, he creates 'a world-out-there' as substitute object, and he places this substitute self squarely in the middle of this substitute world". In Wilber`s writing man creates "symbolic substitutes for lost Unity" (ibid. p. 194) when creating boundaries, and thus compensates the lack within not having achieved the ultimate neo-platonic purpose: reaching the absolute good. However, this is a process depicted as one of creating boundaries where one "must accept the 'death,' negation, or release of the lower level" (Wilber 1984, p. 84f). One must "dis-identify with or detach from an exclusive involvement […] to ascend to the greater unity" (ibid. p. 85).

For Luhmann however, one moves forward with boundaries all the way – they are vital and inevitable since they can create meaning: they force through "time, to think the relation of the exterior world and the interior world asymmetrically as an incline of complexity. And only this way [, by assuming a more complex exterior than interior and corresponding unities impregnated with a difference between actual and possible,] one can acquire a taste of meaningful complexity from the world, the operation wherein the operations by which systems of meaning [, like humans,] operate can find their place" (Luhmann 2012, p. 113). At least, so Luhmann (2012, p. 113) contemptuous, if one is not willing "to immediately re-specify within the ontological-metaphysical tradition purpose onto one preferred and meaningful" – like the idea of the good – as Wilber does.

In *Grace and Grit* Wilber (1991, p. 21) still holds on this truth of an ultimate, though now in the Unitive realm, when he writes that his former wife and love "and I believed in God as one`s own deepest Ground and Goal […]. And by 'God' I do not mean an anthropomorphic father figure (or mother figure), but rather a pure awareness, or consciousness as such, that is what there is and all there is, a consciousness that one cultivates in meditation and actualizes in life". Wilber here uses a "but rather" as demarking a negation that the is unfolded over three tiers. Sri Aurobindo (2003) in one of his earlier works, the comments on the *Isha Upanishad* applies the same pattern when he defines the ultimate in saying that "that which dwells in the body of things is God, Self and Spirit; the Spirit is not the subject of its material, but the master; the soul in the body or in Nature is not the prisoner of its dwelling-place, but has molded the body and its dharmas, fixed Nature and its processes and can remold, manipulate and arrange them according to its power and pleasure" (Aurobindo 2003, p. 431). The recognition of no-boundary and negation here became the definition through negation or categorizing – a unity of being and nothingness. Contrary to handling that negation-categorization Luhmann in the grammatically matching period of his life writes, that for "the accomplishment in theories, that are possible in a semantic space [that can create something like personalization], are founded on a combination of strategies for totalization with strategies of decomposition and evaluation. The play of concepts generates with these boundary conditions its own limitations and non-arbitrariness" (Luhmann 1993, pp. 251f), and thus what a person can be as a comprehensive system and totality, if it wants to be a "wholeness and a sum of detail which can still be grasped by theory" (ibid. p. 251) – he thus reflects from the inside that each wholeness is a mere choice of moving the boundaries of perception while it seemingly can be experienced as an ultimate truth from the outside; there is a somewhat significant stage lag in what is reflected on depending on the identification with inside-Aristotelianism or outside-Platonism.

In Luhmann`s last creative decade, the 1990s, his autological period of observing the mechanisms of observing observers or second order observations, he no longer looks at these reflections on top of the integrative stage and thus the maintenance of systems through integrative self-thematization, but it is the problem of different second order observations that engages his writing. So, he writes in one of his essays in *The Morals of Society* about two modes of second-order observing and the way they are visible "in the cultural invention of normativity can be described as reduplication of reality – similar as one can distinguish between play and seriousness or after the evolution of language between language signs and what they signify" (Luhmann 2015, p. 233). And the foundation for resolving problems of second order conflicts can change in history and can create new problems and paradoxes – as depicted above for the paradox of scarcity. So, in distinction "of a society that assumes a religious foundation of world, we, the now-a-days, can no longer […] summarize these duplications in a transcendental principle" (ibid. 232). The problem for Luhmann back then is that "observation uses its own distinctions as blind-spot. It can only see what it can see with this distinction. […] Any observing, even the observing of observations, proceeds naïvely on this operational basis; or again in other words: that it proceeds uncritically in relation to its own reference" (Luhmann 1992, p. 85).

As we have already seen above, this turns more and more into a "both… and" of self-reference and other-reference, of seeing oneself from differences and unities that create an inside or an outside and different directionality, both within systems and their conscious environment of humans, of observation that can "incorporate self-transcending moments" (Luhmann 2018b, p. 1141) – an immanence recognizing its transcendence within the other or as Georg Simmel might put it: the recognition of the existence of the totality of others in our own being where "both [self-reference and reference through others] are only methodologically assuming a separate existence […] [but] are in an inevitable cycle […] [as] life can only be understood through life, and for this stratifies itself into layers [and others], each mediating the understanding of the other; layers which in their co-dependency proclaim unity" (Simmel 2017, pp. 177f). But for Luhmann the medium becomes metaphorically spoken "the holy spirit of the system" (Luhmann 2002b, p. 286) and the re-entry becomes supplemented and substituted through a mirror metaphor "a self-generated mock […], in whom the communication mirrors itself" (ibid. p. 286). A direction we can, too, see in Sri Aurobindo`s Essays in the Arya Journal however from the opposite side – the solution is not part of a re-entry of the form into form, of difference into difference but a) first "the redemption comes by the recovery of the universal in the individual and of the spiritual term in the physical consciousness.

[…] For then only can the purpose of its descent into material consciousness be accomplished, when the knowledge of good and evil, joy and suffering, life and death has been accomplished through the recovery by the human soul of a higher knowledge which reconciles and identifies these opposites in the universal and transforms their division into the image of the divine Unity" (Aurobindo 1915, p. 385f), in *The Ego and the Dualities* from 1915, – operations which are done by Luhmann`s autological processes of second order observation – and b) second the medium that mirrors back the system into the system as "Sachchidananda […] by laying hold on this secret delight which is at once the secret total delight of its own being and the original all-encompassing, all-informing and all-upholding delight of the transcendent and immanent" (Aurobindo 2016, p. 643), when he writes about *the Double Soul in Man* one year later. Too, Luhmann in his latest writings that span several phases, as he wrote, rewrote and expanded on them during a seven-year periods, using religious terminology made clear that the unfolding of paradox and the mirrorlike nature of media "make the difference of the transcendent and the immanent thinkable and speakable" (Luhmann 2002a, p. 77) and can reach so far that "with or without god, the possibility for a communication of the unity of transcendence and immanence, a communication that therefore confirms that it can find itself in anything that happens, becomes imaginable" (ibid. p. 111).

Final Contemplations

Projections into Luhmann`s Future

In his essay on *Knowledge and Construction* Luhmann in 1988 points out a hierarchy of instrumentals that lead to different orders of self-reference: "the differentiation of systems-reference of the first order observer from the systems-reference of the second-order observer that have to be made by a third order observer" (Luhmann 1988, p. 23). However, in 1997 Luhmann mentions that third order observations "basically are not distinct from a position of second order observing. It is not only a matter of a chain-phenomenon, not only a matter of A observing how B observers C, […] rather a reflection on the conditions of the possibility of a second order observation and its consequences for what than can still be common world or descriptions enabling society" (Luhmann 2018b, p. 1117). Second order observations become autological in Luhmann`s words: the second order observer has to take another observer and has "to locate himself on the inside or outside of a form he observers" (ibid. p. 1118) and by this can in describing his own mechanisms of description create an observation that is located within society, as contingent and not as something existent, as it where for a first order observer thematizing its own life-world. Luhmann describes a re-entry of evolution in itself, of the first distinctions as variation, selection and selective retention into themselves – an evolution that involutes.

Luhmann therefore spoke in the tradition of accidentalism – the inside view – about "the first distinction, […] [which] in the traditional context is relinquished to religion and its theology" (Luhmann 2002b, p. 325). This, when we look at Arthur Lovejoy`s roots of T*he Great Chain of Being* in the Greek culture is, contrary to "the Idea of the Good [that] was the God of Plato, this Unmoved Perfection [that] is for Aristotle the cause of all motion" (Lovejoy, pp. 42 & 55). The struggle for identity expressed in Luhmann`s latest writings as both a) a history of unfolded paradoxes which "not incidentally" (Luhmann 2002b, p. 323) supersede and subordinate each other but in a logical form connected to the evolution of society, which try and fail to succeed in their "communication of the unity of the system within the system" (ibid. p. 319) and b) the "very special distinction, that of […] system and societal system, and about the special problem of an inclusion of […] systems within that which is for them on the one hand located within the inside and on the other hand happens on the outside, namely communication. A difficulty which is not grounded within epistemology or logical impossibility, rather therein, that one has to distinguish and keep in sight two system-references, namely system and society" (Luhmann 2000, p384).

This is a slight reverberation of Ken Wilber`s conflict between two sides of reality in *Sex, Spirituality, Ecology*; namely that of ascenders and descenders which Wilber (2000), too, resolves himself by unfolding a paradox, but on the more Platonic side, making evolution subordinate of involution and so he states that "there we stand now, at rationality, poised on the edge of trans-rational perception, a *scientia visionis* that is bringing here and there, but ever and ever more clearly, to all sorts of people in all sorts of places, powerful glimmers of a true Descent of the all-pervading World Soul" (Wilber 2000, p. 551). He looked at it from the other side: the re-entry and unfolded paradox of involution entering itself as evolution, of holons entering their own pregiven holonic structure.

Why is that similarity of importance for our endeavor? Because it allows us to project Luhmann`s future. In the last sentences Luhmann wrote before his death in 1998 – in *the Religion of Society* and *Organization and Decision*, one might see again a return to a nominal structure. But basically the conflict of systems as necessarily two sides of a distinction leads to the question whether "as system needs a 'self', and whether it is already sufficient to shift from one difference to the next […] [and] shift from one language into the next, to try out, what would be observed then" (Luhmann 2000, p. 442f) and the recognition of the pointlessness of being on one side as it creates both "what it confirms, however, too, what creates the difficulties […] [and] that the reflexiveness of self-description sabotages exactly that distinction, which is presumed (Luhmann 2002a, p. 354f).

When Wilber in his Integral Spirituality introduces the eight zones, he resolves his conflict of ascend and descend with an idea that he in a nominal grammar calls "simple enough. Start with any phenomenon in any of the quadrants—for example, the experience of an 'I' in the UL quadrant. That "I" can be looked at from the inside or the outside. I can experience my own 'I' *from the inside*, in this moment, as the felt experience of being a subject of my present experience, a first person having a first-person experience. If I do so, the results include such things as introspection, meditation, phenomenology, contemplation, and so on. But I can also approach this 'I' from the outside, in a stance of an objective or 'scientific' observer. I can do so in my own awareness, and I can also attempt to do this with other 'I's' as well, attempting to be scientific in my study of how people experience their 'I'" (Wilber 2006, p. 35f) It is a simple "both… and" perspective "since including both of them results in a much more balanced and inclusive approach" (ibid. p. 18).

So, Wilber, managed to combine ascenders and descenders into one point of view, in one map of reality as one territory, while he earlier struggled and subordinated the Aristotelian view to his version of a Neo-Platonism, "the coming of the Over-Soul that is the World Soul, touching each and all with its Goodness and its Glory, baptizing each with its Brilliance and its Blessing" (Wilber 2000, p. 521). By the way, it is the same subordinationistic solution that Aurobindo used 75 years earlier in his essay on the *Graduations of the Supermind*. Namely, that "the greater spirit above the mind appears at first as a presence, a light, a power, a source, an infinite, but all that is knowable to us in it is at first an infinite identity of being, consciousness, power of consciousness, Ananda. The rest comes from it, but takes no determinate shape of thought, will or feeling above us, but only in the intuitive mind and on its level. […] [The descend] of a greater action of knowledge and will and spiritual feeling [that] manifests and seems to organize itself above the mind and this we recognize as the true supermind and the real native play of the infinite knowledge, will and Ananda" (Aurobindo 1920, p. 2).

So, if Luhmann had manifested this next step he would have probably managed to see both: inside and outside, self-reference and other-reference, consciousness and observing, self-thematizing systems as the differences of a new, integrative third, where, using Aurobindo´s description of the overmined – the stage which did not exist in Aurobindo's accusative stage, but was added later as intermediate step to the supermind –, "in place of an uncentred and unplaced diffusion there may be the sense of the universe in oneself or as oneself: but there too this self is not the ego; it is an extension of a free and pure essential self-consciousness or it is an identification with the All, – the extension or the identification constituting a cosmic being, a universal individual. In one state of the cosmic consciousness there is an individual included in the cosmos but identifying himself with all in it, with the things and beings, with the thought and sense, the joy and grief of others; in another state there is an inclusion of beings in oneself and a reality of their life as part of one's own being" (Aurobindo 2005, p. 986).

Alternative Tier-Structure

According to Ludwig von Bertalanffy (1964, p. 48) in his *General System Theory* says, that "a unitary conception of the world may be based, not upon the possibly futile and certainly farfetched hope finally to reduce all levels of reality to the level of physics, but rather on the isomorphy of laws in different fields". In the same sense, we cannot reduce the tiers or orders consisting "of a particular mode or quality of action or thought" (Mascalo & Fischer 2010, p. 156) to one cycle of fours but as shown in table 6, the "both… and" structure both has isomorphic aspects and difference or emergent properties: it is a different unity of differences.

As we have already pointed out: As Luhmann relates second order observations towards Hegel`s absolute spirit, it, as the spirit, is based upon a structure built out of three tiers: namely Being, Essence and Ideas (Hegel 2011). A tier-structure that is common in more structuralist thinkers in the Unitive realm. We have pointed to Charles Sanders Peirce`s (1998) firstness, secondness and thirdness that is followed by a fourth order implicit in his writing and which we earlier mistake for something else: "man is capable of a spiritual consciousness, which constitutes him one of the eternal verities, which is embodied in the universe as a whole", so Peirce (1998, p. 3).

Peirce, too, offers another concept that can foster understanding of emergent properties. As he points out, it is of ultimate concern for understanding his categories to see "the distinction between the Genuine and the Degenerate" (Peirce 1998, p. 172): each of his three categories can appear in full form and in degenerate e.g. the representation of agent and patient as separate and in interaction "is, indeed, germane to Thirdness, while it is alien to Secondness. That is to say, agent and patient as they are by themselves in their duality are not distinguished as agent and patient" (ibid. p. 171) within secondness but just within a third, an interpreter, who can, too, as pointed out again see the unity of these opposites, understand agent through the patient. In the same sense, we have pointed out, that integration in the Achiever writing of Luhmann appears as adaptation and the social dimension as simple form of obedience regardless of one's individuality: it is degenerate and only shows up completely with the third stage in this tier. For Luhmann, too, observations and second order observations, though evolutionary emergent are, ever-present, too: each time and place unfolded paradoxes, though unaware of doing so.

This is true, for the construct-aware stage, too: as it can carry four operations – adaption, goal-orientation, integration and self-thematization – but as it seems has are only three meaning carrying parts in its sentence completion: thesis, antithesis and synthesis; or first, second and third; or evolution, differentiation between system and environment as well as communication. Three minus four means that one operation has to be still in the background, it is there as degenerate and can only show up in a fourth meaning carrying part of a sentence- thus within the next Tier or as Aurobindo puts it: "Supermind is the fourth Name – fourth to that in its descent, fourth to us in our ascension. But Mind, Life and Matter, the lower trilogy, are also indispensable to all cosmic being, not necessarily in the form or with the action and conditions which we know upon earth or in this material universe, but in some kind of action, however luminous, however puissant, however subtle. For Mind is essentially that faculty of Supermind which measures and limits, which fixes a particular center and views from that the cosmic movement and its interactions" (Aurobindo 2005, p. 282). A fourth order that would be the genuine form of self-thematization of an identity maintaining itself by integrating all that is, differentiation within all that is and adapting to all that is, however localized and restricted it might be through its preconditions of being human or a certain type of system. Table 8 depicts the trajectory of tiers.

Table 9. Stage and tier-trajectory with symbolism.

The Tiers	**Firstness:** Being, Body, Evolution, Adaptation, Temporal	**Secondness:** Essence, Life, System/Environment, Goal-Orientation, Factual	**Thirdness:** Ideas, Mind, Communication, Integration, Social	**Fourthness:** Absolute, Spirit, Self-Thematization, Pattern Maintenance, Observational
Symbolism				
If we take a closer look at the concrete stages, we can recognize that the symmetry here is actually not based on four operations but rather the outcome of two – the secondness of agent and patient: one can not only recognize this within the Homeric texts, but, in particular within the old testaments poetic structure of parallelisms (Zenger et al. 2012). In this special type of writing two sentences are added together either in synthetical, synonymous, antonymic or comparative form. One can see this in e.g. psalm 18:14 where there is written "and he sent out his arrows and scattered them; he flashed forth lightnings and routed them" or in psalm 18:4 "The cords of death encompassed me; the torrents of destruction assailed me" as well as in other passages where one can clearly see, who the agent or god it one with his patient the world as in psalm 19:1: "The heavens proclaim the glory of God; The skies display his craftsmanship".

However, this structure is not only common in poetics but, too, in Interviews on moral Dilemmas done by Anne Colby and Lawrence Kohlberg (2010). There one can see the progress through the moral stages through the form this parallelism takes: e.g. on the question why a child is to obey to one`s father, it first looks like a) "[rhema 1 because it`s his father,] [rhema 2 subordinate always he is older]" (Colby 2010 et al., p. 244) and moves to the more complex concrete notions where the agent and patient are integrated like b) "because that`s his son [rheme 1 part one and if he] [rhema 1 part two doesn`t give him,] [rhema 2 part one he would get punished.] [...] [He has to do rhema 3 part one] [rhema 3 part two what his father says,] [rhema 4 or he will get a licking]" (ibid. p. 245) and culminates in c) [rhema 1 part one He should listen to his father] [rhema 1 part two because] if he listens to his father,] [rhema 2 part one his father might be good to him] [rhema 2 part two and give him things he wants]" (ibid. p. 247). Or as Patrice Marie Miller and Suzanne Lee (2007) show, while the cognitive functioning of the 2.0, i.e. Rule-Oriented, individual tends to state "simple, single-action statements about what had happened. These statements can be chained together […] [and] generally [are] focused on subjects themselves or on the other person, but did not suggest coordination between the two, […] [while] [conformist or 2.5] statements were also story-telling statements; however, they either showed the basic coordination between two people, or between two attachment entities" (Miller & Lee 2007, pp. 10f). There, discourse, as on moral stage 6 becomes a lived reality, where within the degenerate third, the still invisible, the communication with its interpretation, two sides are on within the "both… and… and the relationship of both sides to each other". So, here we can see three stages. But this is true for an earlier stage, too, which creates sentences as complex as "[$_{\text{Theme}}$ an apple] [$_{\text{Rhema}}$ on the table]" (Ranti 2015, p. 105) correlating with the Impulsive stage as depicted in Hy and Loevinger`s (2014) *Measuring Ego-Development.* The stage where cognitive development allows people to "verbalize about what they like and want" (Miller & Lee 2007, p. 8).

But there is not only evidence from developmental measurement but as the Jewish philosopher and biblical scholar Friedrich Weinreb (2011) writes in *Number, Sign, Form* the concrete passages of the Tora, i.e. the Old Testament, are full of series of three with a final fourth. So, the creation story of the genesis can be structured as a series "where development from the first over the second to the third day fulfills itself" (Weinreb 2011, p. 50). The fourth, fifth and sixth day give rise to the accidentals of the substances created on the first three days and are their own series. All culminates in the seventh day where both happens "God ended his work which he had made; and he rested on the seventh day from all his work which he had made" (Gen 2,2) – a concrete Form of latent pattern maintenance one might say with two opposite unified as "ending", which sometimes is translated as "finishing", and "resting". More intriguing however is, that the third day and the third in many stories of the old testament is the position where a "both… and…" comes into play that "binds the earlier into a cycle" (Weinreb 2011, p. 51), so is the third and last of the patriarchs both "Jacob and Israel" (ibid. p. 51).

But Hegel`s being, which he himself related to childhood development, and Peirce`s firstness deal with an even earlier order, where according to Jean Piaget (1956) in *The Origins of Intelligence in Children* a child starts to raise external relations "to the rank of symbols by relation to themselves. The image so constituted therefore becomes the signifier of which the signified is none other than the sensorimotor schema itself", which in Peirce`s (1998, p. 161) words might be a "Feeling, or Firstness, to represent itself to itself as Representation" without any second or third. At this stage children basically perform one rhema – phonemes, morphemes, echolalia, doubling of syllables maybe single word statements which include any higher operation of other categories. As Luhmann says the place where "the yes/no bifurcation opens […] to accept or reject an offered meaning […] and thus brings forth variation consequently within a communication directed to refuse communicative contents – it generates one deviant [or aligned] element nothing more" (Luhmann 2018b S.1140 & 2018a, S.460f) and that is the easiest form of evolution which later gets underpinned by selection and selective retention through memory. The speculative tier-structure than looks like it is depicted in Table 9. One can see there the successive substitution of operations from the earlier Tier until with the third stage of the tier all three operations are sourced from thirdness.

Table 10. Tier-Structure and an exemplarily symbolized movement through the Structure of the third Layer.

Aurobindo, Hegel, Peirce & Luhmann				Symbolical Representation	Firstness: Adaptation	Secondness: Goal-Orientation	Thirdness: Integration	Fourthness: Self-Thematization
Spirit	Absolute	The Mistaken (Fourthness)	Observational: Self-Thematization					
Mind	Idea	Thirdness	Social: Communication		Abstract Adaptation  & Two Secondnesses	+ Goal-Orientation  & One Secondness	+ Integration 	+ Degenerate Fourth Life	Essence	Secondness	Factual: System/Environment					
Body	Being	Firstness	Temporal: Evolution					

Whether or not there is a fifth order is an open question in this paper. A possible fifth might exist as additional tier or, as Ken Wilber (2018, p. 401) points out in his latest book within a seeming fourth phase adversary and instrumental grammar using three rhema: "[Rhema 1 part one whereas the infinity and eternity of this wholeness is always already given] [Rhema 1 part two and can never be attained,] [Rhema 2 and the ultimate reality of the entire show is fully present here and now,] [Rhema 3 the relative reality […] has to grow and develop and evolve through time, intentionality, effort, and work]". Differently said, we have to increase the complexity of our observations and distinctions – the media is there, ever-present, everlasting but, too, as a question for the right modes of arbitrating complexity for operability and increasing the complexity of our world through operability and the resulting behavior.

Within this the challenges stay the same though we might find ourselves at one moment of this quest – that for unifying self-reference and the references of others or the consciousness within systems, their operations of observing completely exterior to us, with our consciousness – at a place where we start to life and engage a live that is the discourse of the all with the all. The interplay of any consciousness out there, with any observation, distinction, unity and unfolded paradox within us: but only as a fragment, as a miracle broken out of the mosaic, a oneness that only exists in its dissemination throughout humanity, sentience and the material universe however, so visible and visceral as it is, never apprehended in its completeness. It is merely a feedback from the whole into a part, a short departure and a wrong track of a mind that is meant to be collective, and thus turns into holding the lantern of friar and fabricating the illusions of Maya that are experienced as the hope for a pragmatic consensus and certainty within this endlessly changing and contingent that is held together by nothing more than nothingness as its boundaries – the patterns that can never be seen but through illusions;

a weaving together of communications within that self which is always already and has ever so perfectly been itself, as the incoming of complete other and the dialogue with him, as the dismemberment of the web of life but experienced as its oneness, as its nexus and sole importance as discoursive identity and self-thematization.

Our individual media and grammar and form and lexis both as our identity are thus again and again taken for the impregnation of an alien media and form, degraded to a permanent possession of that which was completed in the same way, as a mosaic tessellated from fragments, a picture that lacks any totality but is complete in itself, as this one moment that is completely monopolized by this discourse with the other, the stranger and alien and is as its own self-alienation in these moments perfectly free and perfected freedom: an eternal quest for versions of inside and outside, accidentalism`s logic and substance thinking or to decide whether to be an Aristotelian mirror or a Platonic sun – a choice that is always to choose our mistakes, too, the next moment of separation as oneness and freedom as abuse within this everlasting distinctiveness and uniqueness of our modes of perception – mistaking means for ends and ends for means, the ominous godhead for a purpose and the dubious first distinction for god while networks and grammars sustain empty patterns and empty patterns are sacrificed for the sake of that one infinity, the discourse that is society, the all and all of communications manifesting what would otherwise be invisible: phases, layers and tiers, that suddenly can have no more boundaries, no longer exist and give place to a new reappropriation of totality completely impregnated by this moment of discourse contrary to the last. While we are thus weaving together what is meant to be separate forever, meant to be dilemmatic and ever-progressive, we are destroying any possibility for union, unless we completely and everlastingly erase our traces, end all distinctions, all differences, all identities within that which is always before and beyond, and thus wake up from that boundless dream that creates nothing but adaptations, systems and environments, integrations and its self-thematization. When we break through into the sleep of all divisions, separations and existences, the error to match the totality and its substance with our contingent observations we engage in the then unseen rupture and disintegration of a tiny fragment of the whole tapestry, eventually rippling out into the farthest reaches of the cosmos and making the end.

Measuring Repeating Patterns: The Concrete, Subtle and Meta-Aware

O’Fallon’s and colleagues (2020) research shows that, in terms of the assessment procedure, her model correlates with Cook-Greuter's model up through the Autonomous, i.e. 4.5 stage; but beyond there both the paucity of data and divergence in stage definitions makes it hard to try to compare them. And hence, there is basically no branch to hold on for figuring out a correlation of the later stages of Terri O`Fallons Model with the two subsections of the Unitive stage we distinguished in the section called *Construct-Aware and Unitive* we only can create some vague assumptions a) based on the descriptions of her stages and b) based on a “look through the hierarchical methods […] [where] we see the horizontal universal essences of everything” (O`Fallon 2019, p. 3) and her seeming developmental stage and on reduction of “looking through the horizontal methods [where] we see a multiplicity of unique expressions that defy replication, yet continually grow and change through time” (ibid. p. 3) into her type within the substance/accidence scheme. By this and the knowledge we unfolded within this paper we are going to pin down four logical fallacies that show up regularly in developmental research and we hypothesize here that they might have been committed by Terri O`Fallon and thus influence the accuracy of her model compared to a hypothetical reflection of the underlying universal substance within which any model of reality is grounded through using its basic operations and distinctions. These hypothetical fallacies are: a) a mixing-types-with-stages-fallacy, b) a decreasing-span-with-increasing-closeness-fallacy that might be, too, driven by a decreasing-span-because-of-increasing-depth-fallacy, c) the misallocation-of-operations-fallacy and finally d) the simplicity-of-categories-and-lack-of viability-through-decreased-diversity-fallacy.

Terri O`Fallon in 2012 writes, that "the expansion [of consciousness] moves beyond individual experience to collective experiences, to contextual experience to experiences of the Kosmos as whole, only step out of that to find that the container that holds this vastness is nothing but a world of Mind that makes distinction" (O`Fallon 2012, p.). Here, we can see the structuralist unfoldment of paradox, where all of the three earlier meaningful operations – "[Rhema 1 part one as changing Interpretations the expansion moves beyond individual experience to collective experiences, to contextual experience to experiences of the Kosmos as whole,] [Rhema 1 part two as Action only step out of that] [Rhema 2 part one as changing of Perception to find that the container that holds this vastness]" – are present as the "nothing but", a categorization, of the more platonic and structuralist thinkers: "[Rhema 2 part two as Awareness of Sprit/Mind a world of Mind that makes distinctions]". The seeming fact that she uses two rhema or one theme and one rhema puts this passage into Luhmann`s autological stage. The grammar points towards a third to fourth phase, including adversaries and "the expansion" and "a world of Mind" as instrumental modifications in form of categories.

Since she, in her *Collapse of the Wilber Combs Matrix*, indicates her personal transition into what she calls the nondual or unified Tier, "as this wondering that seizes one's gaze as one fitfully surrenders mind to the nondual Divine that begins to transcend the kingdom of the mind that makes distinctions" (O`Fallon 2011, p. 24), the second half of the second subsection of the Unitive realm could cautiously be considered as the first nondual stage within her model.

Based on the approximation of her type and her stage, there is a likelihood of a subordinationistic mode within her model that might show up in at least four ways that lead to a) a mixing-types-with-stages-fallacy:

1. One could see, that inside perspectives in O`Fallon`s (2013) stage theory where meant to coalesced with stages showing an inability to prioritize. Thus, accidentalism and the genetic view might easily be seen as less valuable if people move into an over-generalization of seeing more Aristotelian points of view as a sort of mental disability. People might put anyone expressing process-like points of view at these two, the passive and reciprocal stages, while substance and structuralist thinking might falsely be perceived within the active and interpenetrative phases being more valuable as connected with more abilities, most prominent the power of priorization.

2. As we have depicted in the section *From second to fourth phases* and in *Further differentiation in the Unitive realms* the accidentalism`s expression of the Unitive sub-stages includes the unity of opposites within an observer, while the structuralist version includes an interpreter. The later point of view with the third between the second and first might better match "a still point centering between" (O`Fallon 2010, p. 66) a polarity and thus create the impression of a 6.0 perspective.

3. Aggravating point 2: Since, Luhmann and other Aristotelians use the shifting of boundaries and choosing one side of self- and other-reference or inside and outside as well as other dualities like transcendence and immanence, at both the first and second Unitive substage, they fit the 5.5 Transpersonal criteria "of making a choice […] [and]

'move the line' rather than step 'over the line' or 'out of line'" (ibid. p. 63) at all later stages. Whereas the Platonic counterparts already use the 6.0 criteria of having "no self at the center of this stage […] with a sense of universal connectedness" (ibid. p. 67) as well as "a deep acceptance for all of life just as it is" (ibid. p. 67) at the Construct-Aware altitude – at least Wilber does – and thus might be scored later. And this despite not expressing more hierarchical complexity but preferences for lexis and using the available grammar and operations for expressing different experiences. Abraham Maslow in the *Farther Reaches of Human Nature*, already pointed to this difference of Aristotelian and Platonic self-actualizers, where the later "speak easily, normally, naturally and unconsciously the language of being, the language of poets, of mystics, of seers, of profoundly religious men, of men who live at the Platonic-Idea level […] under the aspect of Eternity" (Maslow 1993, p. 273).

4. Since the 6.5 Illumined stage in the *Evolution of the Humans Soul* is classified as apprehending "cross floor and cross world (the concrete world of matter, the subtle world of life and the causal world of mind) patterns" (O`Fallon 2010, p. 68) an these are only foregrounded in structuralist thinkers it might be less probable or even impossible to be assessed at 6.5 for an accidentalism oriented thinker if at the same altitude or level of grammatical complexity as a structuralist and neo-platonic thinker is. As it appeared to us, themes elaborated on by outside perspectives are elaborated by inside perspectives one stage later and maybe not at all – a dependency of stage based on whether identifying with the subject or the object of stage.

These four points in combination and in respect to Terri O`Fallon`s seeming stage and personality type, at least give some rise to the hypotheses that her model could have created a typological gradient into its measures and metrics. It might therefore lead to different assessments than the assessment methodology we proposed here, which as far as possible looks at the number of used operations and creates an assessment on the basis of hierarchical complexity that is expressed within a person`s lexico-grammatical self-expression.

Figure 6 depicts the approximate correlation for the complete stage trajectory including the latest stages thus paying credit to the hypothesis that Terri O`Fallon`s model includes a mixing-type-with-stage-fallacy as reasoned in the above section. Additionally, the table makes visible that each the Pluralist or 4.0 stage as well as the Autonomous or 4.5 stage only make up for half a stage compared with the earlier ones described in Ego-Development theory. The comparatively decreased scope of both stages leads to an increase in the number of stages at the upper end of the Loevinger and Cook-Greuter scale and since this scale was adopted by O`Fallon this increased density at the upper end represents another logical inconsistency that seems to be within the sediment of her model, the b) decreasing-span-with-increasing-closeness-fallacy that might be, too, driven by a decreasing-span-because-of-increasing-depth-fallacy.

Figure 6. Comparison of the trajectory with hypothesis about Terri O`Fallon's model of human development.

The scopes and boundaries of a stage normally don`t play a major role in assessing, if each stage has its own independent descriptions and scoring criteria based on themes and topics like in the work of Hy and Loevinger (2014) as well as Cook-Greuter (2010). Contrary, if measurement is based on a repeating pattern varying boundaries and breadths of stages as well as tiers can be seen as an indicator of internal contradiction. Alternatively, there would be a need to modify the set of assumptions and principles behind the model. This could mean to include a notion that later tiers embrace for whatever reason less span. However, it is not atypical for models to commit a fallacy that leads to an increase in the number of stages at a certain point of the trajectory, mostly at the upper end: Wilber`s full spectrum model (2018) does not depict all the earlier stages and additionally has an increased density in the middle of the trajectory and towards the end; Graves (2006) ECLET is getting very dense at the later stages and Commons (2016) MHC conceptualizes several hypothetical stages at the upper end. The reasons for such a fallacy might be twofold: a) there is increasing depth with each stages that might be confused with span – the early and late versions of a stage are much easier to discern – and b) that like with an approaching car, the closer it comes the faster it seems, and thus the closeness leads to reasoning about increased speed or hence, an increased number of stages; it is some sort of Doppler shift: the change in frequency of a wave in relation to an observer who is moving relative to the wave source. Given the assessment of Terri O`Fallon`s stage – and the hypothetical accuracy of that assessment – in the beginning of this section it is most likely that her model falls in the decreasing-span-with-increasing-closeness type of this fallacy with the so called meta-aware tier as the smallest, spanning just two and a half stages compared to the approximately eight stages of the concrete tier and the three of the subtle tier. Figure 6 graphically illustrates this observation for the mentioned models.

According to the assumptions of the here depicted model each person if once entered the fourth Tier displays the ability to express quadruplicities within one sentence rather than triads – with the quadruplicity as an ability that is displayed in degenerate form even earlier but only fully fledged within the fourth order of consciousness. Thus, it is just natural that tier models at the latest stages depict patterns of fours instead of patterns of threes like Kurt Fischer (1980) and Erich Jantsch (1979) in the culmination of the third tier who have just a degenerate fourth – a fourth which is at the same time a first: mistaken so to say. As Carl Gustav Jung (1977, p. 619) puts it in his *Mysterium Conjunctionis*: “the alchemical formula for this is the Axiom [...]: ‘One becomes two, two becomes three, and out of the Third comes the One as the Fourth’”. Exactly because four operations are available now, these operations can be used to dissect reality and allocate judgments within the spaces surrounded by differences – and this includes like in the natural sciences that immature explanations deceive much of reality, like the idea of a flat earth vailed the possibility to circuit planet earth. If we use our modalities of consciousness to look at something real, something with a material correlate, our stories can err dramatically and thus confine our possibilities.

To further explicate this thought we can use one of the main assumptions of a Peircean pragmatism, that is, even our subtle models of reality, like schemes of categories and orders of stages, are not only a pragmatic consensuses, but, too, have reality and failing “to recognize the reality of all the categories […] would point out the fatal defect of” (Peirce 1998, p. 181) a system. However, recognizing categories is not enough since the pragmatists summum bonum lies “in that process of evolution whereby the existent comes more and more to embody those generals which were just now said to be destined” (Peirce 1998, p. 343) – this primarily means the categories` growing into themselves and self-thematizing their own existence. And the potential reality and match with something real creates the main question each developmental model proposing repeating patterns has to face from our point of view: are its applications of the four meaningful components of the fourth tier`s operations applied in a way that matches the reality behind the surface expressions within consciousness and thus the model fulfills the destiny of our observations, reasoning and creation of stories or does it fall short of reality. Since as Wilber (2006, p. 272) puts it: “because once a level has evolved, it is a very real structure existing in the universe […] (cosmic habits or cosmic memories) [that exist] independently of any particular human and become something that all humans must confront.”

Does a model come close to that which is disclosed within another sphere, does it approximate the transcendental categories that “are transindividual or collective cosmic habits, which push against any human psychology and guide its growth" (ibid. p. 272) along a trajectory of relatively even and repeating patterns, these disclosable living realities that are not only human constructs but can carry constructs which are applied towards themselves within a functionally fitting manner? For if not: these transcendental functions and the fabric of reality becomes malformed and distorted maybe even to the degree of a rupture that might end all of humanity and at the very least creates the illusion of natural order and hierarchies where non are given – is it a tool of injustice and oppression of the facets of consciousness and evolution itself or is it their self-liberation towards itself? We can make this more tangible by an example: The famous psychoanalytic and expert in child development Margaret Mahler writes in the *Psychological Birth of the Human Infant* that "the normal separation-individuation is the first crucial prerequisite for the development and maintenance of the 'sense of identity'" (Mahler, Pine & Bergmann 2000, p. 11). A maladaptation to the child's need in this sensitive period by caregivers can lead to "the psychotic child [that] never attains a feeling of wholeness, of individual entity, let alone 'a sense of human identity'" (ibid. p. 11). In the same way are person with late stage awareness the obstetricians and midwives as well as fathers and mothers of late stage awareness and maladaptation to needs of the wards can have similar outcomes on their psychological birth into the most sophisticated forms of human consciousness and reasoning.

The original dilemma comes from our twofold condition of which pragmatism somehow describes the convergency towards absolute truth, whereas the conditioning of our mentality is better described by the constructivist schools as only seeing relatives. Both sides play together in our consciousness where the coalescence with the phylogenetically grown absolute reality, the application of these transcendental functions or stage and tier operations habitual to our cosmos, can only produce contingents, actualities that can always be imagined to be different, since they are based on each observer's observations within a merely closed ontogenetically formed system as well as in its structural coupling with certain modes of societal discourse and self-thematization. As far as "everything that is happening in a living system, in the factual operations of its elements` properties, […] operates solely in the present that is, it is determined by the structures, which it possesses in the moment of its structural self-realization" (Maturana 2000, p. 182f) each living system and consciousness is challenged by a special condition when the tier operations are turned back on themselves – when the relative tries to grasp the absolute, when the object apprehends the functions of the subject, or the inside looks towards its outside: contrary to observations of other mental realities, that are as interpretations and imaginations quite subtle and fluid and represent no absolute truth but generate truth in hindsight, the observation of the subject itself is an ongoing observation turned back on the quasi eternal truth of the substance these categories are. Thus, where the form tries to recognize its media, that means the accidentals their substance, contingency is contingent to what it`s contingency is built of and irrespective of this condition tries, within that contingency of its descriptions, to recognize the unconditioned and essential. The recognition of the underlying substance or transcendentally structured ground of consciousness that was involved into our brains and minds by millennia of evolution, which are therefore to a certain degree habitual, material and solid. Missing them thus can deteriorate the reenactment and reappropriation of evolution with itself and its merely permanent grooves as the involutionary structures we enact in our very consciousnesses similarly to the idea of a flat earth which did thwart the discovery of new shipping routes.

The idea that stages and patterns are cosmic grooves opens up the possibility for an inconsistency that we can call the misallocation-of-operations-fallacy. While the allocation of the operations to the world is more a creative and constructivist endeavor, the search for the best stories and descriptions of the autopoietic processes that generate their own criteria of beauty, truth, clearance and goodness able to ride on the surface of the original transcendental media – a media that is generalized by the functions of the tiers and their grammatically and thus adaptative, differential, integrative and self-thematizing possibilities – looking at consciousness itself has like the natural sciences a clear restrictedness through reality, where ships don`t find routes or even worse the miscalculation of an equation can lead to devastating effects – like the meltdown of a reactor or a psychotic child or deformed late stage adults despite the best intents of the actor. A model in this set of assumptions generates its aggregate value fourfold: a) by enacting creativity within the discourse and making it adopt to better stories, b) by reappropriations of what is real beyond the purely contingent, however contingent and ever-unfolding the reappropriation is, c) by potentially or eventually changing the mode of integrating ourselves into these media and generating new forms of enacting and synthesizing through these categories and last but not least d) to discern whether or not theses reappropriations serve the harmonization and maintenance of the evolutionary whole or leads to its deterioration. Both approaches thus not only relate to different truths and means-ends orientations but, too, to different imperatives when it comes to the conceptualization of models – despite being intriguingly connected. Since tending towards describing the absolute truth behind the contingencies can lead to absolute errors it needs absolute imperatives and practices that lead to the best possible reappropriation of the invisible. Figure 7 graphically illustrates the considerations about the misallocation-of-operations-fallacy.

Figure 7. Two ways of creating models of reality and their implications.

One seeming absolute imperative creates the possibility for d) the simplicity-of-categories-and-lack-of viability-through-decreased-diversity-fallacy. As Zachary Stein and Katie Heikkinen (2009) write in *Models, Metrics, and Measurement in Developmental Psychology* privileging of “deep-structural properties indicative of development […] allows us to measure and assess development in many lines using one metric” (Stein & Heikkinen 2009, p. 12) but at the same time models doing this “dubbed structural properties as indexes of development: for example, they privileged attention toward properties like differentiation/integration, concreteness/abstractness, simplicity/complexity” (ibid. p. 12). The priorization of a complex web of measures that are not only aligned with each other but calibrated across different models – for the realm where models with metrics and measures exist – and authors’ life works decreases the overall value and worth of one measure and thus reduces risks. Similar to a hedge-fund on the financial markets, the bundling of investments that have a dispersion across markets and economic sectors, the bundling of metrics and measures reduces risks especially those generated by our very human nature`s typological and cultural biases. The whole point, too, can be broken down into Ashby’s (1956, p. 207) law of requisite variety: “Only variety in […] [the measures] can force down the variety due to […] [the diversity of humans]; only variety can destroy variety”. This is what we call d) the simplicity-of-categories-and-lack-of viability-through-decreased-diversity-fallacy.

The fact that Terri O`Fallon`s model basically has crystallized out of the soft measures, “metrics with mainly qualitative standards for determining the amount of a trait” (ibid. p. 7), derived from Cook-Greuter and Loevinger, a mere mono-logical arising from only one tradition of measurement combined with the reduction to only three variables for measurement – tier, individual vs. collective and ability to prioritize or not – as smart and elegant it might seem could even increase the vagueness of “meaning making assessments […] [which are anyway already] expected to be a bit fuzzier and imprecise, compared with application of Skill-Theory” (Murray 2017, p. 52) and other grammar-based assessments in general and thus decrease the viability of the overall scheme of transcendental truths behind our observations and distinctions.

This fallacy or rather taken risk – if the reasonings in this paper are partially or completely true – might be responsible for all other fallacies since they are all easily avoidable through a discoursive approach that considers multiple models and metrics and thus enables oneself to apprehend errors within one`s reasoning through the multiple voiced field of knowledge surrounding each observer as his or her milieu. A pragmatist`s perspective has to be a consensus both with others and with what is ultimately real and true behind or as the media that consciousness is – a state of nonduality that is the prerequisite of a discourse of the all with the all or the self-thematization of human mind in a larger field or the social sphere – which is only possible through a discoursive approach – since oneself is always merely an individual rather than a general.

The comparison with other models can, additionally to pointing out the comparatively uneven and premature tier-shifts, question some other basic assumptions of Terri O`Fallon`s model. We already mentioned that passive language seems to be possible across all stages and all phases. Too, if there were a tendency for passive language would this be an indicator of a person’s ability to prioritize? For Kohlberg the priorisations-pattern would look completely different: for him the person at moral Stage 6, which should approximately correlate with the 5.0, i.e. Construct-Aware stage, is “able of completely reversible ‘role taking’” (Apel 2016, p. 331), which can lead to principles of justice like Kant`s categorial imperative and Rawls principle of justice as fairness. It is the priorization of an internal or external discourse with a difference of actuals and possibles and a purpose which is suspected to make ends meet. One`s stage 6 “moral point of view, from where the individual can orient itself within the questioning of right and justice” (Apel 2016, p. 321) allows to prioritized certain universal principles that serve as meta-rules for discourses or internal practices that not only see one point of view but are “the perspective of a ‘moral point of view’, from which societal order is derived […] that accepts that each person is a purpose in itself” (Kohlberg 1996, p. 132). This is an ability which Kohlberg saw lacking within the assessments of people at moral stage 5 – O`Fallons interpenetrative and therefore prioritizing stage. These individuals could apprehend to procedures or contextual rules "that integrate different perspectives through the mechanisms of formal agreement" (ibid. p. 131), but still only through one`s own or larger systemic context`s point of view. Contrary for O`Fallon the Construct-Aware individual is denoted as passive "with little ability to prioritize any of the constructs that one is seeing" (O`Fallon 2010, p. 61).

Again, this incongruency is owed to the seeming premature tier shift compared to the depicted model in this paper. Since for Apel (2016) and Habermas (1990) moral stage 6 and thus construct aware was a stage of complete reciprocity within the abstract realm, it would rather be depicted as collective than individual and the foundation for priorisations thus is collective as the grammar of the action oriented and beneficiary applicative as well as derived intransivity could indicate – a mode of priorization that might be less visible when one looks at the stage as centering around a 1st Person.

But how could one explain the seeming misallocation-of-operations-fallacy and thus the different Tier-shift? We already mentioned that for Hegel, Luhmann and others the first and fourth within a tier are most similar to each other, even though they are basically opposed to each other as being subject and being the pure subject as I-I or being the substance of the me, you and all, the self-thematization of a system including even what it negates or excludes as its boundaries. Since the fourth in the subtle tier is simply degenerate and cannot be completely present within three meaningful sentence parts performing a quadruplicity the expert and construct aware match each other in so far as they both can hold two poles through a third: the 5.0 stage with two subtle poles as the "both… and… and the relationship of both to each other" and the 3.0 stage as the mental holding two sides or operations of the concrete. Figure 8 illustrates this similarity.

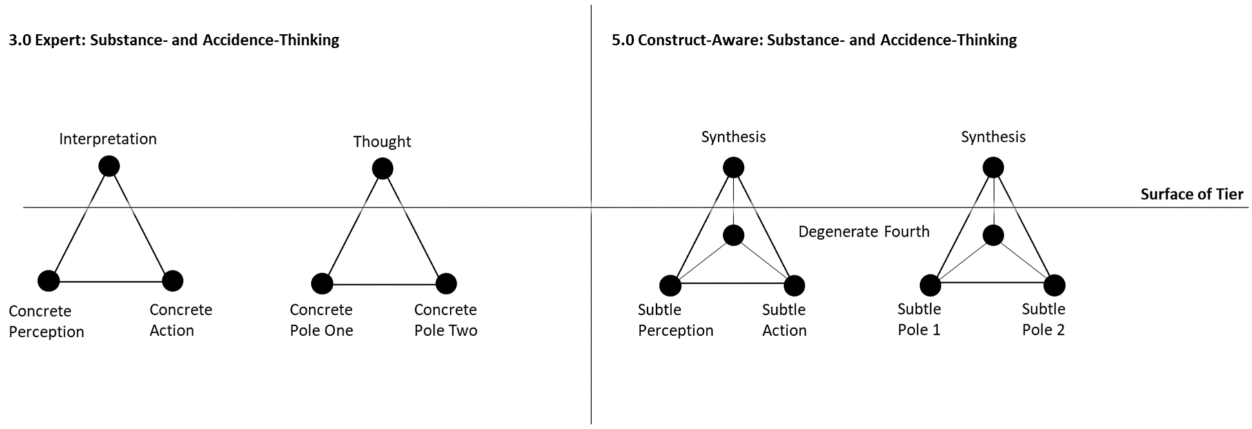

Figure 8. Similarities between the 3.0 Expert and the 5.0 Construct-Aware stage.

However, all of this were not a problem if not an even overarching pattern was asserted which if it existed misallocated at least an individual or adaptative stage where a collective stage of full reciprocity should be according to other models and an even iteration of the quadruplicate tier pattern – a flaw that surely generates an upward domino effect. Additionally, the distribution of four stages into two and a half potentially leads to further maltreatment of assessed persons and only works through other biases like the type-stage-fallacy as long as the reasoning depicted in this section is scientifically sound and further supported by other observers.

Table 11. Potential Fallacies committed within Terri O`Fallon`s Model.

Fallacies that might be Committed	**Characteristics and potential Effects**
Mixing-types-with-stages-fallacy	Seeming subordination of Inside Views →At least delayed stage shifts for Inside View persons →Unnatural hierarchies and power structures (punishment of persons with an inside view on reality)
Decreasing-span-with-increasing-closeness-fallacy	Increased Number of Stages at the top →Uneven Tiers and misallocation of operations →Measurement with repeating patterns of passive, active, reciprocal, interpenetrative should be logically impossible without perceptual biases that distort assessments towards expected outcome
Misallocation-of-operations-fallacy	The seemingly existing repeating patterns or tier-operations are misallocated →Uneven Tier Shift and mismatch with deeper reality →Potential maltreatment of people
Simplicity-of-categories-and-lack-of-viability-through-decreased-diversity-fallacy	The seeming cause of the hypothesized problems as lack of fourth tier discourse orientation and oversimplified as well as overgeneralized measures →Inadequate management of scoring risks →Threatening overall health of universal trajectory

O`Fallon`s and colleagues` (2020) latest publication which claims the validation of her new scoring method allows us to take a look at how both our systems come to same or different results in scoring since “Appendix 3: Scoring samples from the Concrete, Subtle and Met-Aware tiers” (ibid. p. 12) includes scoring examples.

1. “At times I worry about… the future of my country.” (O`Fallon et al. 2020, p. 12) was scored at subtle, individual, active 3.5 Achiever and would be a second to third quarter, third tier, first stage score by the here depicted method, thus Expert. It includes only one abstraction and is written in an accusative-possessive language. Concomitantly Hy & Loevinger (2014) rate the completion “…the future of the world” at E5 Expert through scoring category 5r contrary to scoring category 6r E6 Achiever “…the future of society and, indeed, of civilization” including two abstractions.

2. “Change is… inherent in living and connecting in the world; it prompts me to shake myself off from the slumber of consistency and embrace the excitement of newness” was scored at subtle, collective, reciprocal 4.0 Pluralist and would be fourth quarter, second stage, third tier and therefore exiting Achiever with the here depicted method. Though, depending on the overall assessment it might be interpreted as a single “both...and” phrase of “living and connecting” and to continue with another “both…and” of “prompting to shake of” and “embrace the excitement” and henceforth would include three abstract components in one meaningful composition – a Pluralist or Autonomous rating it is more likely that we deal with an Achiever version of

"both… and" or exiting stage "unity-between-opposites" insofar as "to shake myself off from the slumber of consistency" and "embrace the excitement of newness" are merely coextensive or synonymous and only a reference switch or co-subordinate to each other.

3. "When I get mad… knowing that uncontrolled unleashing of the power I now access can create undesired damage, I recognize the feeling tone in my awareness and I take myself on, stepping toward what brought on the anger, as I know that the emotion points at the growing developmental edge I have asked the universe to stretch" was scored at met-aware, individual, active 5.5 Transpersonal and would be a third to fourth quarter, first stage, fourth tier and thus Unitive response. It includes four components "[First Component knowing that uncontrolled unleashing of the power I now access can create undesired damage,] [Second Component I recognize the feeling tone in my awareness] [Third Component and I take myself on, stepping toward what brought on the anger,] [Fourth Component as I know that the emotion points at the growing developmental edge I have asked the universe to stretch]" including a lot of dative and locative grammar within the oneness of two opposites: "the feeling town in my awareness makes me take on stepping towards the anger an outside and at the same time it is my inside, the developmental edge I have asked to stretch".

4. "Women are lucky because…as the canvas they contribute to the Universes' particular paintings in the Sacred's art gallery by continuously receiving the brush of many colors, and thus are formed by the timeless, never ending layers of humanity's pigment" was scored at met-aware, collective, reciprocal 6.0 Universal and would be scored at fourth stage, fourth quarter of the third tier, at the late Construct-Aware stage. It includes only three components organized in an instrumental fashion: "[First Component as the canvas they contribute to the Universes' particular paintings in the Sacred's art gallery] [Second Component by continuously receiving the brush of many colors,] [Third Component and thus are formed by the timeless, never ending layers of humanity's pigment]"

Here one could again evidence a type-stage-fallacy: the inside view "oneness of opposites" at the first Unitive stage is assessed at an earlier stage then the outside Construct-Aware completion that is using overly spiritual and metaphoric language as we already know it from the conflict within the Aristotelian and Platonic writing traditions: where earlier is famous for its syllogistic reasoning as well as carving out of principles while later is known for its rich analogies and metaphors.

Final Overview

Within this paper we moved through Luhmann`s career as a systems-thinker. We started from the. Achiever, and ended with Unitary, so far as we use the terminology of Susanne Cook-Greuter. We could see changes in grammar and changes in conscious preoccupation, as well as these in interpersonal mode and character or identity development. Anything we found was already pointed out by Luhmann himself. In one or the other way we rode the web of his life with the sparkling horses of anything but only him. We silently assumed many things and we put into words some others – we coded and decoded into their own semantics a number of texts. These are listed in the final table. We cross-referenced not only with linguistics but with thinkers of other domains, too, depicting something that still can be doubted and should so. As it is only a web of grammars and words: a contingent within contingencies trying to apprehend in a reappropriation the universal substance we are made of in order to serve the reduction of complexity, operationalizing a life that can sustain itself through creating new and more adequate complexity.

If there is one more thing to mention – as Luhmann shows in an extraordinary way: stages don`t disappear once lived through, they always stay and have to be cared for and nurtured and re-entered to resolve the paradoxes of life. Table 11 shows some of the highlights on his fruitful path we investigated here and from which we were so richly nourished.

Table 12. Some of Luhmann`s writings depicting his life as a writer and across several stages.

Stages			Books on the Trajectory					
Achiever	Goal-Oriented	3rd Period						The Formal Organization (1964)
		4th Period	Basic-Rights as Institutions (1965)

STAGES
Methodological Principles for Future Enaction

Trisha Nowland[1]

Introduction

This paper begins in invitation from Tom Murray for this special edition of Integral Leadership Review, to provide alternative perspectives on the STAGES Matrix model. The perspective I am offering here is based on my recently completed theoretical PhD in psychological research methodology, accompanied by an enduring interest in developmental psychology, psychoanalysis, and data science. My background with the STAGES Matrix model comes via participation in the Generating Transformational Change (GTC) program in 2011-12, which was co-founded by Terri O'Fallon (who is no longer a principal with Pacific Integral, the same organisation). This was followed by engagement in several winter programs in Integral Polarity Practice with John Kesler and Thomas McConkie online since 2012, who both reference STAGES within IPP sessions (see conversation in this special edition). They have also worked closely with O'Fallon to continue to innovate the STAGES model. The background is given here both to describe my experience with STAGES, and to acknowledge the limitations of my expertise on many of the emergent subtleties of the STAGES Matrix model as currently taught by its primary representatives, Terri O'Fallon and Kim Barta.

The content of this paper derives from an interest in thinking through how the post-formal developmental levels described in STAGES could be applied to the very processes of researching and theorizing about human development, specifically, in psychology research. I feel a tension between the more complex construct-aware, context-aware, relationality-aware, and process-aware capacities pointed to by the STAGES 4th person-perspective (and higher), and the simplistic method of modeling development in terms of a single linear stage sequence—one which describes its outcomes without reference to the examiner, or study context. Note this tension exists for most developmental models in mainstream psychology, as well. Thus, the principal question pursued in this paper is:

> How could the capacities described by "4th person-perspective" offer deeper contributions to psychological theory and practice than is currently in seen linear stage-based developmental models in psychology research?

---

[1] **Trisha Nowland** presently convenes Sydney Integral, and has supported the Integral Polarity Practice South Pacific community since 2012. With diverse interests spanning mathematics, philosophy, and psychology, she has recently moved on from a 15-year career in information systems in finance to begin practice as a psychologist, working with communities at the margins in Sydney's suburbs. She is a Generating Transformational Change (GTC) graduate, and has in the last year completed a doctorate which developed a set-theoretical model for integrating qualitative and quantitative methods in psychology research. She currently works as a researcher in Australia's non-profit sector, and remains as a passionate reader in continental philosophy, psychoanalysis, Marxism, and Vajrayana Buddhism. nowlandtr@gmail.com

SOME RIGHTS RESERVED

The question perhaps seems fraught, at first glance; STAGES uses person-perspectives to exactly describe its levels of ego development. In what follows, we will work to disambiguate ideas about ego development levels from ideas about person-perspectives, drawing on the history of the ego development concept as founded in the work of Jane Loevinger. We will then explore how person-perspectives as a concept offers unique discursive resources (Chase, 1995) to psychology methodology literature. The question above is posed as important for psychology research, to the extent that 4th person-perspective offers perhaps the most appropriate way to account for the effects of social and cultural phenomena in the psychology research paradigm. The psychology research paradigm and its mainstream applications remain largely uninformed with respect to what 4th person-perspective methods of inquiry may entail. It is proposed in this paper that the greatest contribution that the STAGES Matrix model makes to psychology research may not necessarily be the refinement of categories of ego development levels, but may be best characterised by how methodology can be refined by taking into account 4th person-perspective - something rarely encountered in conceptualizations of "scientific" inquiry, in my experience.

In pursuing the question above, some tensions are drawn out for the STAGES Matrix. We begin by orienting to the STAGES model as described by the "three questions" of the STAGES Matrix, shown below.

Figure 1. STAGES matrix Three questions. From: https://www.stagesinternational.com/about-the-model/.

There are three key principles that can be directly noticed in the above table. The first is a recurrence of patterns, particularly for the elements of Social Preferences and Learning Styles, with specific start and end points for these. The second key feature of note is the alternating swing between individual and collective in the Social Preference question. The final key feature of interest is an absence: a lack of an account of the embedded social and cultural context as an embodied being, which we must exist within, in order to have any opportunity for STAGES to unfold. This last point brings into view some indications for generative advancement with respect to the nature of assessment, for the STAGES Matrix. The sections that follow are ordered accordingly. Firstly, we address some **philosophical or foundational questions** for STAGES, noting a reliance on pattern-making that accompanies this model. The mid-section orients to questions of **relationality,** specifically for the individual-collective polarity, shaped by literature on social meta-cognition and psychoanalysis. The final section takes as its departure point the concerns made clear in the first and second sections, and offers some insights on **methodology** for psychology research that makes use of sentence completion test data. We begin with historical and philosophical perspectives in personality psychology, as we consider the origins of ideas that found the STAGES Matrix.

Philosophical Perspectives

In what follows there is an effort to retain systematicity as a quality which is beneficial to psychological research, and in this section there is an effort to remain systematically *historical* in what follows. Rather than extending across the terrain of "a theory of everything", then, there is a tracing of the particularity of the beginnings of ego development theory in the work of Jane Loevinger. A recent paper from O'Fallon (2018), "STAGES: Everything is a perspective" identified building on the work of Jane Loevinger, by proposing a structural model that does not rely on content from participants to guide the structure of ego development theory. For O'Fallon, this is stated as important to allow for continuous updating of the sentence completion tests to socially and culturally relevant phenomena of the time:

> Models that only use categories of content will continually have to update that content because it is constantly changing even though the perspective is structurally the same. Having models that have structural parameters can continue to score as the content changes. (O'Fallon, 2018, p. 20)

The shift that is articulated is one that steps beyond the taxonomic approach to characterising the levels of ego development pursued by Loevinger, later extended by Torbert and Cook-Greuter (see Kegan, Lahey, & Souvaine, 1998, and Appendix 1 for details). Loevinger collected data from a large number of participants, and sorted these into categorisations, based on theory developed by Harry Stack Sullivan from her early work researching authoritarian parenting styles. The groupings of phenomena that shape her account of ego development come directly from participants, and what she was observing as clusterings, around particular ego development levels, or worldviews.

What is proposed for STAGES is something different. The theory begins from a hierarchical and repeating structure for the construct of ego development, that can extend below the levels of linguistic abilities necessary to fill in the sentence completion tests that provide the assessment information for any one individual, and can extend past into higher levels as chartered for example in Wilber (2000, 2016) or Aurobindo (1990). What is preferenced for STAGES is orthogonality in structure, rather than the imprecise overlap of organic clusters grown from data gathered over time, as seen in Loevinger's categorisations.

Loevinger's approach to psychological research has been identified as consistent with constructivist realism (see Slaney, 2017, p. 185). For Loevinger, this meant that the data collected by psychologists described traits that occurred in individuals, while psychological constructs were something that existed in the minds of psychologists, principally:

> Traits exist in people; constructs (here usually about traits) exist in the minds and magazines of psychologists. People have constructs too, but that is outside the present scope. Construct connotes construction and artifice; yet what is at issue is validity with respect to exactly what the psychologist does not construct: the validity of the test as a measure of traits which exist prior to and independently of the psychologist's act of measuring. It is true that psychologists never know traits directly but only through the glass of their constructs, but the data to be judged are manifestations of traits, not manifestations of constructs. Cronbach and Meehl and their colleagues on the APA committee appear reluctant to assign reality to constructs or traits. Considering traits as real is, in the present view, a working stance and not a philosophical tenet. (Loevinger, 1957, p. 642)

For Loevinger then, the construct of ego development had a logic and meaning mostly in the hands of fellow psychologists and researchers, built from the data that she collected from participants, informed by stage-type conceptions of Piaget (1932) and Sullivan (1953). Her perspective on traits is important for our considerations here as it appears that her conceptualisation of traits is as descriptive summaries useful for clinical intervention, not as internal causal psychological properties, of humans. With the structure for STAGES seen in the image above, there appears to be an implied characterisation of ego development that is closer to the latter rather than the former - it appears there is a causal engine assumed in the polar structures adopted, in the STAGES model. Loevinger on the other hand had built her account of ego development theory into what she self-described as a scientific paradigm, or disciplinary matrix:

> A scientific paradigm is shaped by its data and in turn shapes them. No simple Baconian program for data accumulation nor hypothetico-deductive program for disconfirmation of hypotheses encompasses that dialectic, still less a program based on factor analysis, multiple discriminant analysis, or random computer searches of data. There is a corresponding tension in our conception of people, not surprisingly, since scientists are people. Much as we have learned about how the structure of character evolves and is maintained, there will always be more. I do not count as failure but as an act of courage to admit that the heart of the matter is and always will be a mystery, opaque to the scientific glance. (Loevinger, 1976, p. 433)

Our question then for STAGES becomes one of whether the patterns so repeating gives psychologists and researchers a well-defined space, as scientist-practitioners (see Barlow, Hayes, & Nelson, 1984), through which we can understand something of personality characteristics, as developmental levels. Loevinger herself had aspirations to develop “a sub-discipline within psychology that inherits some of the wisdom of philosophical psychology, that unites the discoveries of psychoanalytic ego psychology with contemporary stage-type conceptions of personality, and that has its own research methods and sphere of applications” (Loevinger, 1966, p. 433). While STAGES in some ways appears as a continuation within the sub-discipline, aspects of its structure mark it as perhaps something different. One apt characterisation could be, as a person-perspective construct. We'll talk more about how the notion of a person-perspective construct might benefit psychology and particularly psychology research methodology, below.

Ego Development Theory – The Deeper History

As described above, the roots of STAGES are found in Jane Loevinger's ego development theory (O'Fallon, 2018, O'Fallon & Barta, 2017). Ego development is described by Loevinger following reflection on psychoanalytically-informed psychology in the following way: "The ego develops as the person works to master his experience; yet what requires to be mastered and what is acceptable to him as effective in mastering depends on ego level" (Loevinger, 1966b, p. 441).

Loevinger articulates an account of ego development abstracted from the work of Sigmund and Anna Freud, stated in Piagetian cognitive development terms, with the idea that interpersonal schemas are internalised into intrapersonal schemas, according to the level of a person's ego development. Her account is distinguished explicitly from ideas about self-mastery, or self-improvement such as would be found in today's coaching paradigms, as in Loevinger's terms such a theory was merely self-referential, just announcing, that ego development does occur (see Loevinger, 1966b, p. 441). Rather, her proposal is that the interpersonal schemas become in some way part of the unconscious apparatus by which a person makes choices in living their lives, which are described by her as "symptoms."

Loevinger's (1976) later body of work (see Manners & Durkin, 2001; Loevinger, 1998) extends Harry Stack Sullivan's (1953) model of ego development as a self-system built via his research with young male schizophrenia sufferers. Sullivan's model had three components constructed from elements including: a) character development representing the combination of impulse control and moral behaviour; b) conscious preoccupations, including the kinds of things a person orients to in thought; and c) interpersonal style, representing attitudes towards interpersonal relationships. Loevinger (1976) adds a component for cognitive style, which represents the shift from conceptual simplicity to conceptual complexity at later levels. What follows then is an account of ego development that describes progressive redefinition of the self-structure contextualised by the social and physical environment (see Manners & Durkin, 2001).

The ego itself for Loevinger (1976) as conceptualised in ego development theory is a construct held in the minds of researchers that captures the structural unity of personality organisation, where personality is made up of traits[2]. Loevinger (1976) refers to ego as the "master trait," which holds any other possible developmental domain, for example worldview conceptualizations (Perry, 1970), moral development (Kohlberg, 1969, 1981; Piaget, 1932), and interpersonal understanding (Selman, 1980). For Loevinger, while there was an inner logic to the progression of change for personality (Manners & Durkin, 2001; Loevinger, 1976), she did not pursue explication of this inner logic (see Kegan et al., 1998). She maintained to the very end that the sentence completion test methodology provided insight into the function of the self or ego in a way analogous to an immune system, protecting the person and their current frame of reference from experiences of cognitive dissonance or inconsistency (see Loevinger, 1998, p. 352) within a certain environment. It was in a way, less about structure, and more about responsivity to the cultural and social context that the individual found themselves in; emphasizing a paradigm that had been largely unarticulated within psychological research in Loevinger's era.

---

[2] Note that personality psychology as a field remains undecided about whether personality features have qualities that are inflexible over time, such as traits that we are born with, or whether personality is made up of contextualised responses to more immediate situations, which are states, see for example, Steyer et al., 1992)

Ego Development - The Relevance of Context and Relationship

Loevinger's home for constructs as residing in the minds of psychology researchers, and less so in the immediacy of the lives of persons that make up populations, speaks to an aspect of psychological research often elided - the presence of the researcher as theorist and modeller, or sentence completion test scorer in assessment, in the account of the score that is given for individuals. To be scrupulous about this observation - in the tradition of psychology research journal articles in the broader field of psychology research, the researcher is not included in the report of the statistical outcomes that are offered as the scientific support for the structure of the psychological construct (whether it be a STAGES ego development construct, or something else).

Originally the aim of the omission was an attempt to remove researcher bias from the reporting of research outcomes, such that the study report reflected an unbiased and objective scientific outcome (see Barlow et al., 1984). The technique of not including researcher perspectives is not different from quantitative psychological research more typically of Loevinger's day, and remains not different from other psychology reports, today. The STAGES approach of leaving out the perspective of the researcher or the scorer is no different, in this respect then, from mainstream psychology. No account of the stance of the researcher is typically articulated, in the reporting of the outcomes of a study. What is more, no systematic account of the commitments of the scorer is made available to a person undergoing a STAGES assessment, where they would be given opportunity to understand for example the different social or cultural positionings that the scorer occupied, to know something about how this might shape the scoring given, in the STAGES outcomes.

This lack of presence of a researcher in quantitative reporting however is very different from reporting techniques in qualitative psychology research today, where an account of the researcher's perspective is included in enhancement of social trustworthiness and dependability of the research outputs, in terms of evidence in respect of research project validity, for findings (see for example, Shenton, 2004). What we know today, distinct from what perhaps was clear across the field of psychology of Loevinger's time[3], is that researcher bias necessarily shapes what is reported in respect of a psychological construct, and also has a role in each decision made about the statistical analyses which provide scientific information about the construct, as well as methodological determinations (see Nowland, unpublished thesis). What this implies is that the most ethical stance that a researcher offers to other practitioners and the broader community, one which reduces the quality uncertainty of results (Vazire, 2017) is one where full transparency is adopted, with respect to philosophical commitments, for the construct in question.

---

[3] Loevinger's own work with construct validity however provides some evidence that she herself had clear understanding of the problem.

The lack of inclusion of researcher perspectives points to a broader concern for the history of personality research, and one that is really relevant to research work that builds on Loevinger's ego development theory as STAGES does, transmuting the insights by including fixed structural elements with polar facets, as we see in the Matrix. In the era that Loevinger developed her theory, for the purposes of psychological research, there was no well-pronounced differentiation between the social realm and the cultural realm, for psychology, tracked in systematic ways in research methodology. What this meant was that psychological constructs were generally created, and then, replicated, without reference to the context of their development. In the language of STAGES, 4th person-perspective is simply not included in the data, and is barely attended to in the methodology, of psychology research (see for example, Poropat & Corr, 2015). To understand the difference between social, and cultural realms, what is needed is 4th person-perspective.

4th person-perspective is described in Angerer (2018) as "a focus on an observer, observing another observer, observing another self and other(s)" (p. 154). In the STAGES model this is available at 4.0 Pluralist and 4.5 Strategist, respectively. What this would mean was available in the scientific methodology of psychology was a systematised account of say, the ideological stance relevant for the scientist-practitioner who was recording observations about the implications of social and cultural practices implicit in the administration and scoring of a particular test or assessment between a researcher and a participant, such as the sentence completion test structure that is used to assess STAGES. The reason that this is important is that the worldview of someone else, as is proposed to be assessed via the STAGES model, is not assessed 'from nowhere' - it is assessed in a series of transactions between a researcher or scorer, and a participant. The meaning that is generated from a sentence completion analysis has to be culturally and socially embedded - the score can come from nowhere else but such a place. To the extent that the researcher or scorer themselves is as culturally and socially embedded as the participant, it would seem beholden on the researcher or scorer to account for this embeddedness in a systematic way which facilitates the interpretation of their score or assessment. The resulting score or assessment is a function of an interaction between the cultural and social backgrounds of each of the stakeholders - the researcher and/or scorer, the model developer, and then also, the participant. It is not peculiar to the participant, alone.

Social systems need to be differentiated from cultural influences, that are relevant to a cultural construct. The reason that this is important is that social systems will have much to do with *how* we observe a specific psychological phenomena - social systems can influence for example, the conceptualisation of intelligence as a function of an education system, or an attitude as a function of a political system. Social systems also connect to how we calculate something like a score for a psychological construct such as a STAGES score, for example using sophisticated statistical software that may make the method of calculation of the score somewhat obscure, to the person who is completing the psychological assessment. One risk with not including information about the social system is that the extent to which there are social system-determined processes at play in the outcomes seen for an individual assessment is not available, for scrutiny. An articulation of what components of an assessment are social system-relevant seems important for being as thoroughgoing as possible in offering someone a perspective on what is notionally, their own worldview, as is an outcome of a STAGES assessment. 4th person-perspective facilitates the reporting of social system information, insofar as the way that the system interpenetrates with the social situation of the test itself is actually available for reporting.

Cultural systems on the other hand influence *what* we take into consideration when applying the label for a psychological construct. For example, a Western conceptualisation of the individual-collective binary may be vastly removed from an Eastern conceptualisation of the same phenomenon, where articulations of self-structure in each of these global villages involves different amounts of the presences of other people, in the conceptualisation (see Pauly, 1995). Where we have an Eastern individual completing a Western assessment which is scored by a Western assessor, the nuance that is relevant to the particular meanings of words as found within the originating culture may be largely unavailable to the assessor. Reporting of cultural background, by the model creator, by the assessor, and by the participant, creates the best possible opportunity that what is reported in the assessment actually is relevant to, the individual who is being assessed.

What was not the case in the era of Loevinger's work, and what we do not yet see in a standardised way for psychology research in our time, is a 4th person-perspective routinely accounted for, either in the methodological structure of a study, or in the records and data that is used, to assess individuals. Both methodology and data are still de-contextualised, with respect to 4th person-perspective. The context of research is consistently left out, of the methodology and data that we work with, in psychology, and psychometric practices relevant to reported outcomes. In the next section we explore some aspects of contexts which seem to be highly relevant to the STAGES matrix, and specifically focus on the relational context of development, with reference to psychoanalysis and the transactional model of development (Sameroff, 2009).

Context of Ego Development

In what follows we explore two avenues of enrichment for STAGES with respect to 4th person-perspective considerations. One is the extension of relational psychoanalysis and the transactional model of development that emerged in the decades following Loevinger's work, the second is looking to methodological advances for psychological and personality research based on the PhD research of the author of the present paper.

What is at stake in any ego development model must have some sort of relation with the autobiographical self, which itself is conjectured to have basis in autobiographical memory, which itself has been demonstrated to be a function of relational and family narratives (Fivush, 2019). More than this, there is a significant body of work in developmental psychology that describes how a life script is a function of a culturally shared schema, which determines how and in what way life events occur (Fivush, 2010). This schema is prescriptive, which means that individuals who deviate from the culturally-shared script are called upon to explain their life story, to account for their trajectory of development in culturally-relevant terms. Even in the upper reaches of development then, there is some constant connection for an individual to other as parent, others as kin, and the collective as social and cultural structures. To articulate something which is universal in its relevance, such as is implied at the broader stages of embrace (see O'Fallon & Barta, 2017), but which is also able to be understood in a specific social and cultural context, one must rely on the signifiers that are relevant to the people of that society, and culture. We live in a time today where sharp attention is oriented to surface small differences that make a very big difference for the individuals who have inherited specific cultural and societal understandings of certain symbols, and who suffer a type of trauma when atypical understandings are introduced, such as is the case for indigenous communities (see Pauly, 1995; Clancier & Kalmanovitch, 1987). There is an opportunity to reflect, here, on how to represent 4th person-perspective pluralism with deep integrity, as relevant, to this time, and in a way which echoes forward, to future times.

What seems important, in an account of a construct such as STAGES, is a recording of the ideological, social, and cultural context for the *individuals* who undertake the STAGES assessment, as well as for the researcher or scorer, as referred to above. This is because the data must be interpreted with respect to the intersection of these instances. What is needed, then is an analysis of the ideological, social, and cultural contexts adopted in the STAGES construct, combined (perhaps, correlated), with the ideological, social, and cultural context of the assessed individual(s). What we have then is a more complete picture of what STAGES is able to tell us, about the construct of ego development in a contextualised picture, as it is reflected in the responses of individuals who live out their lives, in contexts. Ultimately what we're saying here, is that we're always situated within contexts, and today, we have the technology that facilitates a much clearer picture of how contexts shape human lives. The final section provides some insight as to how to account for contexts using technology, in a coherent and structured methodology for psychology research.

STAGES as Tracking "Meaning Making"

> It is clear that there is an absolute essentiality to the encounter with the Other. If there were no encounter with the Other, the reflective dimension of consciousness would somehow remain an inert part of the in-itself. What activates it, what makes it present to itself as what it is, is the fact that another consciousness apprehends it as participating in the being of the Other. (Badiou, 2019, p. 30)

In this section we extend our vision for the evolution of Loevinger's ego development across the terrain of relational psychoanalysis and a transactional model of development. My understanding of the relational nature of psychological development is informed by work as a psychologist in a trauma clinic for children. The nature of the trauma experienced by the children presenting at the clinic was complex interpersonal trauma; the extent to which there are developmental implications from such trauma experiences is well-established in psychology literature (Streeck-Fischer & van der Kolk, 2000; Putnam, 2006). Research of ecological-transactional models that are relevant to such circumstances demonstrate the relevance of the social world and cultural context of events related to developmental challenges (Lynch & Chichetti, 1998). The intrinsic connection between development and relationship in context cannot be avoided in reference to this body of literature. With this in mind, it would seem that in any account of a construct such as ego development as relevant to children and adults, that the relational structures within which the individual functions are adequately accounted for, in any model of the construct or phenomenon.

In the literature of relational psychoanalysis, Mitchell (1988) proposes that, in founding psychoanalysis, Freud established the wrong unit of study for psyche, by orienting to individual minds. The more apt unit of analysis according to Mitchell (1988), is the relational or interactional field. This is particularly the case when we come to consider aspects of adult meaning-making in the context of a construct such as ego development. From our earliest days, we are continually in interaction with others and our environments, and our transactions shape us as we shape our relationships, and social and cultural contexts (Sameroff, 2009). Our experience is built from these elements, and our meaning is a reflection of the sets of correlations that occur for us as beings with the environments, societies and cultures we experience ourselves within. Nature and nurture are not dichotomous in this view, and social relations themselves, experienced through time by autobiographical selves, can be understood as shaping what come to be expressed in sentence stem responses that can be encoded as an ego development level - whatever the model of development that is at hand. The basis of experience in physiology means that different modes of expression are entirely possible beyond verbal language - an account of social relations makes possible an analysis of a developmental trajectory that is not merely founded in verbal report. De Waal (2009) notes that ethics emerge from the ability of mammals to relate to one another. Co-operation, familiarity, emotional connection and resonance all are qualities that emerge in relationship that do not in and of themselves depend on linguistic ability. We may need an understanding of fully evolved consciousness that does not rely on human linguistic skillsets, to evaluate the true universality of later perspectives. But what we can say is that there would be no development of these capabilities without transactions in a social and cultural context.

The import of the suggestion above about correlating fourth-person information for both the assessor or researcher, and the individual who is assessed is made clear in a quote from Mitchell (1988):

> Meaning is inherent in man’s physiology, his biological equipment. Thus, the individual mind has a priori content, which seeks expression within the larger social environment, either in absorbing the culture, in learning public rather than a private language, or in taming and channeling drives. For relational-model theorists, as for the modern anthropologist and modern linguist, the individual mind is a product of as well as an interactive participant in the cultural, linguistic matrix within which it comes into being. Meaning is not provided a priori, but derives from the relational matrix. (p. 19)

Mitchell includes this, from Eagleton: “[o]ur experience as individuals is social to its roots; for there can be no such thing as a private language, and to imagine a language is to imagine a whole form of social life” (Eagleton, 1983, p. 60).

The relational matrix model has something to say about how repeating patterns such as the ones featured in STAGES come to be part of human life:

> The relational model rests on the premise that the repetitive patterns within human experience are not derived, as in the drive model, from pursuing gratification of inherent pressures and pleasures ... but from a pervasive tendency to preserve the continuity, connections, and familiarity of one’s personal, interactional, world. There is a powerful

> need to preserve an abiding sense of oneself as associated with, positioned in terms of, related to, a matrix of other people, in terms of actual transactions as well as internal presences. (Mitchell, 1988, p. 33)

The addition to the STAGES Matrix that is suggested via reflection on the relational model is one where the space between the individual and their broadening yet more intricate appreciation of the social context is nurtured. Relation can be mapped by model design, looking to the physiological basis of functioning. Relatedness can be mapped by constructs that assess intent, which orients more to the motivations of the individual, including for example, the motivation to hold some form of social contract to complete a sentence completion test. Relationality can be mapped finally by implication, where some proxy construct provides information about relational features - for example using person-perspectives, to map an individual's understanding of relationships (see Mitchell, 1988, pp. 33-35). What is important about a relational model is that you cannot logically account for the relationship, without accounting for the characteristics both nodes via which any relationship comes into being.

For human individuals, our existences are defined by the relationships we find ourselves inhabiting or are embedded within, as well as the relationships we may verbalise in a sentence-completion response. If variation in sentence completion responses can be in part mapped by changes in social, cultural and environmental changes, these nodes deserve representation of some sort, in perhaps some broader matrix within which the STAGES Matrix sits (see next section). It may eventually become very important to conduct such mapping as our environment begins to rapidly change, producing rapid social and cultural change, with it. Certainly our shared experiences with bushfires in my home country of Australia (in the summer of 2019) have lent us an understanding of the need for adaptive, reflexive environmental responsivity, enacted at all levels of the collective. In evolutionary psychology terms, for example, we know that imitation in a social ecology relies on both creating resemblances between beings but also on the availability of other mental representations which are shaped and limited by interaction with other cognitive systems and the environment (see Russon et al. 1998). To speak beyond the limits of what our earthly environment may present (see Cook et al., 2016), from meditative traditions we can also understand that the realisation of "suchness", for example, makes available to the meditator "the ability to see oneself and all other things of the world with "perfect clarity" just as they are in the context of their relations with one another" (Huntington & Wangchen, 1989, p. 82). What this hints at is that the highest realisations make available clear, precise and responsive *relational* data, and nothing else.

Musings on Methodology and Models, for STAGES

> I have some of the same misgivings about reducing the variegated, multifaceted nature of personality development to a single continuum with a handful of milestones that Loevinger expresses. . . it reduces in a manner unwarranted by reality the complexity of personality. I wish personality development were as simple as that. (Jackson, 1993, p. 33)

As pointed out in section 2.0 above, the lack of an account of the perspective of the researcher is one of the features of psychology research, and STAGES as a model and as an assessment appears no different in this regard. This poses some amount of risk for a developmental model which intends to be universal in its application, as O'Fallon (2018) indicates with the proposed articulation of structure by which sentence completion content can be assessed, in the STAGES matrix. It is understood in academic, but perhaps not yet broader circles, that scholars typically assume their own experiences in their contemporary culture as a baseline for deviant and normal development (Pauly, 1995). This can result in mistaken interpretations and assumptions, in the shared space between the researcher and the participant. It has been noted in academic literature for example that other cultures do not load adverse childhood experiences into their accounts of problems in dealing with life troubles or later-life developmental pauses (Hillman & Ventura, 1992). Also noted in the literature is the sense that not all childhoods produce the same social and environmental interactions, they cannot be presumed as similar (Narvaez, 2019). Perspectives matter, when it comes to inferences about the content of sentence completion test responses - no matter the extent of confirmation of inter-rater reliability. These perspectives are formulated within lives that are socially and culturally embedded, and which may not have much coincidence in view, even at higher levels of realisation where universals may be much more apparent in the responses provided by the participant.

For the Future

Such a proposal as the one made in the last sentence of the previous section returns us to the possibility of combining 4th person-perspective data from the researcher, and 4th person-perspective data from the individual. A recent research thesis from the present author worked to found a framework within which reporting of outcomes from psychometric analyses could be contextualised in light of disclosure from researchers regarding their ideological commitments, and social and cultural perspectives, as well as methodological assumptions. In the thesis this is argued as vital, as it is impossible to produce outcomes from statistical analyses of psychological constructs without subjective biases entering into the sets of decisions that are functional to producing such statistical analyses (see also Nowland, Beath, & Boag, 2019). Such biases may include for example beliefs about whether psychological constructs are measurable on a continuous ratio scale structure, as is necessary in performing Rasch analyses (see Murray, this issue). Collection of detailed 4th person-perspective data from the researcher and from the individual regarding, for example, the individual's experience of sensory differences, or distinct cultural, social, and environmental ecologies renders the data collected in the name of ego development interpretable in new ways. Nowland (unpublished thesis) proposed a set-theoretical structure to report such information, given that mathematical set theory is the most universal of mathematical languages, and that it maximised the opportunity to articulate something about the trustworthiness of the research outcome in qualitative terms, or in this case, the proposed STAGES level, for an individual who completes a sentence completion test. What was argued for was a network structure facilitating inference from the best systematisation, overcoming a number of limits associated with the 20th-century vanguard of inference to the best explanation. Ultimately what can be imagined with a coherent systematised collection of such data is a refinement of the STAGES model in light of new clarity with regards to how relationships, experienced by individuals, shape a shared space for perspective-taking, in all its possible guises. Modelling STAGES in this conceptual framework may have reflexive gains, as the conceptual framework is re-shaped with a vision of 4th person-perspectives, and as STAGES itself becomes thus also, changed. Inspiration may be derived from Varey (2015):

> The formation of coherence generates a set of relational tensions. The continuation in a direction enables a feature of reliance in a set of coactions. The reciprocal tensions of coactions become locational around contributive relations. These locations of reciprocity become reliable as potentials for generativity. The recurrence of potentials enables future potentials as probable possibilities. The entrainments of the future potentials set the conditions for the formation of new coherences. This generative process is seen as contextually dependent, multidimensional and self-generative. The hypothesis formed is: The praxis of being enables future becomings. (p. 15)

Appendix: Loevinger's Characteristics of Level of Ego Development

Characteristics					
Level	Code	Impulse Control	Interpersonal Mode	Conscious Preoccupations	Cognitive Style
Impulsive	E2 (I-2)	Impulsive	Egocentric, dependent	Bodily feelings	Stereotyping, conceptual confusion
Self-Protective	E3 (Delta)	Opportunistic	Manipulative, wary	"Trouble " control	See above
Conformist	E4 (I-3)	Respect for rules	Cooperative, loyal	Appearances, behavior	Conceptual simplicity, stereotypes. clichés
Self-Aware	E5 (I-3/4)	Exceptions allowable	Helpful, self-aware	Feelings, problems, adjustment	Multiplicity
Conscientious	E6 (I-4)	Self-evaluated standards, self- critical	Intense, responsible	Motives, traits, achievements	Conceptual complexity, idea of patterning
Individualistic	E7 (I-4/5)	Tolerant	Mutual	Individuality, development, roles	Distinction of process and outcome
Autonomous	E8 (I-5)	Coping with conflict	Interdependent	Self-fulfillment, psychological causation	Increased conceptual complexity, complex pate terns, toleration for ambiguity, broad scope, objectivity
Integrated	E9 (I-6)		Cherishing individuality	Identity

Deconstructing Developmental Constructs: A Conversation

Thomas Jordan[1] and Tom Murray[2]

Thomas Jordan has been a valuable appreciative critic of the STAGES model and of ego development models in general. In his publications over many years he describes a variety of skill sets important to higher level adult development, for skillful dialog and deliberation, and for dealing with the complex ("wicked") problems that our society faces. What follows is an edited and cleaned up version of a series of email exchanges between Thomas and Tom Murray. We initiated this dialogue in early 2019 with the hope that it could be turned into something publishable in this special issue. Our only guideline was that we tried to end each segment with a question. Murray posted the first question. We have added section headings post-hoc to help organize the conversation.

Note that subsequent to this email exchange, Thomas and Terri O'Fallon had a videoconference conversation about her model, which has been transcribed and is available at: http://www.perspectus.se/tj/ConversationOFallonJordan.pdf.

A. Differentiating Developmental Theories

TM: What do you see are some of the dangers or drawbacks of developmental models such as Kegan's, Cook-Greuter's, and O'Fallon's, that describe a single developmental construct or trajectory that is supposed to capture many aspects of human meaning-making (as opposed to models with multiple "lines" of development)?

TJ: The most immediate problem I see is related to the conception of late stages of development. I have followed research and theory building in the ego development and hierarchical complexity fields for several decades now. I believe that there is a fair measure of correlation between levels of cognitive complexity, in the social and

psychological domains, and stages of ego development in the preconventional and conventional parts of the spectrum, and maybe also in the early postconventional stage. However, I think that what is really significant about late postconventional, and even more transpersonal, stages cannot be explained by increasing complexity and levels of abstraction of mental representations. There is a quite different dimension of development that has to do with noticing internal processes and gradually disidentifying with the thoughts, emotions, desires and other goings-on in the mind and the body, giving rise to an increasingly strong capability for witnessing.

I am sure that the patterns described by O'Fallon's framework do exist, and maybe the stage sequence she describes is the most common pattern for people who reach the later stages. But I believe it can be misleading and confusing to use a framework that assumes that there is a single line of development that accounts for all transformative shifts in adult development. I believe a person can be capable of very complex cognitive operations without having much of a capacity for witnessing the self's processes. And conversely, I believe that a person can have a well-developed capacity for witnessing internal processes without having a capacity for or habit of constructing meaning in very complex ways. (For example, see Jordan (2011, 2018) in the References). I find the ego development frameworks you mention very meaningful as heuristic devices, but I think that they should not be taken too seriously.

I have a hard time believing that a framework that posits a single line stage sequence, which the STAGES model seems to do, can adequately represent the variability in how people evolve in their capacity for handling complexity as described by theories of hierarchical complexity (Commons, Fischer, Dawson and others) on the one hand, and their ability to witness the constructed nature of their experience on the other hand. What do you see is the relationship?

TM: I think this is a really important inquiry, and I confer with your concerns and probably with many of your opinions about the later levels. Regarding the role of different theories, first I will say that I put Kegan's theory of meaning making maturity in the same boat as the ego development theories – Kegan implies in his writing that they are very similar constructs (with different measurement methods; cutting up the same developmental spectrum in different ways). Let's call it meaning-making (MM) for now (ego development for Loevinger; and O'Fallon sometimes calls it "perspective taking" levels). I will also use CC as shorthand for cognitive complexity (i.e. hierarchical complexity) – so what is the relationship between MM and CC? – that seems a central question for us.

Speaking *theoretically*, putting aside the empirical correlations for a moment, I see two key differences between MM theories and theories of CC development in the hierarchical complexity tradition (HCTs).[3] One is that MM theories map what happens when you take cognitive complexity (CC) and turn it *inwards* to understand the world of

---

[3] I am framing some of this from the perspective of the model I am developing on "Wisdom Skills," which draws heavily on Terri's STAGES model but is also influenced by Bonnitta Roy, the neo-Piagetian models (Fischer, Commons, Dawson).

I/my/you/we/our/them/theirs – i.e. the everything that is not an "it" (social, emotional, and self skills). (I hesitate to call this "interiors" because it does not quite capture it – but it is close Wilber's "LH side.") Lets call it the domain of the "*ego-involved*" – i.e. all occurrence or proposition that are emotionally tied to "me" – which includes relationships to me, as in my, you/our, we/us, they/them; all of which are ego-involved because they are defined in relationship to, and often in tension with, the self.

The second difference is that MM theories incorporate aspects of *unlearning* as well as growth (learning) in hierarchical complexity. Despite the common idea that the developmental arc starts with building the ego and then moves to deconstructing the ego (which does contain a lot of truth), I think ego development has moments of unlearning all the way up – something must be let go of and transformed at each major fulcrum. The two moves are related, one turns CC toward the self; then one does the subject-object move of seeing some new aspect of the self, and then, for ego development to happen, one "sees through" that old pattern and releases or re-contextualizes it (this picture is missing an important element having to do with state-stages but I'm skipping that for now). Unlearning is related to shadow work and contemplative practice – with deconstruction, de-centering, healing etc.; and (I say more about this in the Wisdom Skills work) in the unlearning one re-claims or re-members something that was always true about the self that one had hidden from the self.

This turn inward is related to Wilber's notion that "the cognitive line leads" – since CC is generally built up in learning about the exterior world first. This is built into the STAGES model that posits that learning generally happens with exteriors before interiors.[4] For example, one learns about the concepts "angry" (concrete) or "prejudice" (abstract/"subtle") first when adults point to it in others – the first step is to recognize it "out there." Only later does the child realize, oh! "*I* am angry" or "*I* am prejudiced" (which can instigate deconstruction of some narcissistic belief, i.e. an ego growth).

An important piece here is that certain aspects of the interior (or the self) are more *complex* than others. So one can't really grasp them until one has built up enough CC. The CC is usually first developed in reference to exteriors because that is usually a safer context in that it does not threaten to destabilize the self. Also, seeing things outside the self is more concrete, vs. interiors are more subtle. For example, understanding that "I can do bad things while not being a bad person" is a big step for a child; it requires a certain level of complexity (differentiation and integration of certain concepts), and until that happens the child will have an ego structure compelled lie about her socially unacceptable behaviors. At an even more complex level, to see the self-structure as a collection of interacting drives/voices (or, even more complex, sub-personalities) allows the ego to mature, or move closer to what we might call spirituality (or complex ethics). The ability to see "systems" of this complexity (first in exteriors) is a prerequisite to developing this type of self-knowledge.

---

[4] Interior/exterior, the fourth parameter in the STAGES model, is not as often mentioned as the other three: Tier, individual/collective, and active/passive. The stage is defined by the primary three parameters. The fourth parameter helps determine early/late within a stage, but this level of granularity is not used in our statistical studies, and unlike the other parameters, we have no empirical evidence as yet about the validity of that part of the model. But the principle of exterior before interior coordinates with other psychological theories (and see Mark Forman (2012): “All the stages of identity development, therefore rely on different forms of outer-directed cognition eventually being used in the inner world of the self” (p. 80).

Does this notion of unlearning relate to your understanding of the nature of adult development?

B. Shadow, Developmental Tiers, and Spin-outs

TJ: I have not thought about that angle, it certainly seems worth considering. And it could possibly make for an interesting dialog with adherents of the hierarchical complexity theories on adult development, since the conception of stepwise processes of differentiation and integraton on higher levels of complexity is not well suited to account for what you call unlearning. So please go on elaborating how you see the relationships between unlearning, shadow, ego development and cognitive complexity.

TM: Terri (and Kim Barta) use the concept of shadow and healthy horizontal development to account for some of this. That is, ego development level shows something about one's capacity to understand shadow material and the deeper self in more complex ways, but it does not say whether one uses that capacity to heal their shadow and do the hard work. As we all know, you can reach late levels of ego development (based on the assessment) and still have a lot of shadow. No one as far as I know has a good assessment for shadow (of course we would need to define shadow better) – that is another area at our community's leading edge. This relates to what I said before RE one difference between HCT and ego development is that the later is better able to theorize about shadow work.

Terri, and especially Kim, use the STAGES model to talk not only about growth, but to identify the developmental level associated with shadow elements. Horizontal health (what Kim calls full "surface area") at each foundational level is more important than how "high you climb." In a similar way, I think what advanced contemplative practice is doing is deconstructing assumptions that are so deep in the psyche that they are the basis of our *perceptual* constructions of time and space (and self) that formed in infancy. Psychotherapy deconstructs developmental phenomena like attachment dynamics, usually from the first few years, and contemplative practices target even earlier development like basic sense of self, time, body boundaries, the subject-object split, etc.

So MM (ego) development is about the growth of CC in a particular domain – the self. MM development and CC development *should* correlate empirically because MM relies on CC (that is, increasing complexity contributed to increasing ego development, but ego development is more than that). MM development seems better equipped than to talk about (1) the phenomenology and nuanced of self-growth, (2) shadow-work and de-centering; and (3) the more spiritual, esoteric, and state-based aspects of later level ego development. HCTs are tuned to talk about the mechanisms of building complexity in *any* domain, and when applied to some domains include movements of reflective abstraction (self-knowing); but they are weak in talking about the unlearning moves that are so essential to ego development. Ego development, on the other hand, is weaker on describing the precise cognitive mechanisms of building complexity. It does include unlearning in its understanding of growth, but neither of the theories has a very solid model of unlearning. Unlearning is better covered in theories of psychotherapy and contemplative practice, but in general mechanisms of unlearning are not as well understood as mechanisms of learning. I think the challenge of bringing all of these together is at the leading edge of our theories.

As you imply, the MM assessments don't explicitly separate out the complexity of "out there" objective content from ego-involved (more interior) growth. Do you know of studies that empirically study the correlation the various aspects of development we are talking about?

TJ: Unfortunately, there is very little empirical research that tests whether different aspects of adult development, such as hierarchical complexity, ego development stages and self-awareness are strongly correlated or not. The few studies I know of have very small sample sizes and have methodological problems. It would be very interesting to see what happens if a reasonably large number of persons were tested with 3-4 different types of tests: sentence completion tests, analysis of complexity levels in spoken or written discourse, performance in tasks that require high levels of cognitive complexity and something like Kegan’s subject-object interviews, but developed to look for advanced forms of self-awareness, witnessing and ego transcendence.

I do not advocate scrapping ego stage frameworks in favor of only operating with multiple lines, but I would like to see more recognition among theorists that there is a large variability in the late forms of adult development. I look forward to the publishing of far more empirical data and richly described case examples from those who use the STAGES framework. So my question would be what reasons you have for believing in the validity of using a linear sequence of stages that positions the transpersonal stages on top of the most sophisticated postconventional stages?

TM: Totally Thomas – the empirical evidence on all this is insufficient and we need lots more. RE whether the transpersonal capacities follow directly after the cognitively sophisticated postconventional stages...I think I agree that it does not *have to* (it depends on the meanings of these terms of course). One aspect of Fisher's (and Dawson's) model that I like, that Commons' model does not have, is the idea of increasing levels of abstract object types (sensorimotor, representations, abstractions, principles), and within each such "tier" there is increasing complexity (single objects, object relationships, systems, new wholes). The STAGES model has this same kind of structure. (You speak to this in your 2018 paper).

TJ: Is Terri's "subtle" tier really the same as Fischer's/Dawson's abstract tier, or are there differences? I would also ask how the Metaware objects represent an advance that directly builds on the abstract tier.

TM: We don't have much empirical evidence on how they correlate yet, but theoretically, the STAGES 3.0/Expert maps to Commons "Abstract" and to Fischer/Dawson's "9. Single Abstractions." "9-Single Abstractions (Abstract), 10. Abstract Mappings (Formal), 11. Abstract Systems (Systematic) maps to STAGES 3.0/Expert, 3.5/Achiever, and 4.0/Pluralist (completing the STAGES subtle tier we have 4.5/Strategist, which maps to "12. Single Principles (Meta-systematic)."

But that is not the whole story. As I mentioned, the Fischer/Dawson/Commons models only measure CC, while MM requires CC *applied to* the inter/intra-subjective domain, so you can be high on CC and not have the equivalent MM stage if you don't apply the CC self-reflectively. So the models diverge in that way.

RE the metaware tier: I think at each tier there is a whole new emergent set of phenomena, so it does not build in the same way. For example, formal operations jump into a world of abstractions that are not a straight continuation of what is going on in the concrete tier. One can continue getting more hyper-complex with concrete reality, and not develop abstract thought. Yet abstract thought *requires* concrete thought.

Given that CC growth is necessary but not sufficient for MM growth, the CC of understanding the exterior world can increase indefinitely without necessarily applying it to those realms of experience that tug on (threaten or create dissonance with) the ego. I, my, you, us, ours, they, theirs – this is the realm where the ego has its attachments and aversions and blind spots. Ego defenses keep us (all of us!) from applying our CC from knowing certain "truths." (You know all this, I am just building up an argument here).

Terri talks about a pattern she calls horizontal "spin out" which happens at the top of any person perspective (PP) – one can keep getting more and more complex and not grow in terms of ego development. So I would hypothesize that there is some *minimal* level of complexity needed to robustly understand some aspect of I/us/they. The minimum is necessary but not sufficient; and more than the minimum will deepen I/us/they insight; *but* there may be diminishing returns so that beyond a certain point it may not add to development very much and more complexity so it spins out horizontally.

For example, at the concrete level (2nd PP in STAGES) one can understand and create super complicated mechanical devices (like a genius mechanical engineer) but still not have developed much abstract thinking (a 2.5 spin-out). With abstractions and hypothetical thinking (3rd PP in STAGES) one can develop super complex scientific, philosophical, or technological ideas, but they may still be linear in the Newtonian sense, may still have that "there is one best answer" feeling, and not move into groking the realities of mutual-dependence, feedback loops, ecosystems, fractal structures, etc. The interdependence, fractals, and comfort with multi-perspectives characterize 4thPP thinking. Terri also points out that from 4th PP you can spin out into super-complex "systems of systems of systems..." (at 4.5) without getting into the space of more emptiness-of-self and construct awareness of the Metaware tier.

We don't have to be wedded to the STAGES levels, but this idea that complexity can increase and spin out horizontally without creating the next level of hierarchical ego development is very useful.

Does that relate to your question?

C. Questioning Holistic/Wide Lines vs. Specific Skills

TJ: In part, but I still believe that the whole ego development theory tradition rests quite heavily on the assumption that there is something like an ego as a ”structured whole”, and that it therefore makes sense to talk in terms of, for example, a ”center of gravity”. Theo Dawson maintains that this is an erroneous assumption, given the empirical fact that people display different levels of complexity when grappling with tasks in different domains. But Theo belongs, I believe, to the scholars who are strongly convinced that levels of complexity is the one and only significant variable explaining different patterns of adult development. If you believe this, and you know from empirical studies that individuals' performance in terms of complexity varies significantly in different domains and under different situational conditions, it follows logically that the notion of ego development stages must be untenable. Of course, ego development theorists don't accept that interpretation of the nature of adult development. You specifically address this issue elsewhere. However, even if you don't accept the premise that adult development is only a matter of cognitive complexity, it would be a good thing if you and other ego development theorists can address this kind of criticism and provide sustainable arguments for the idea of the ego as a structured whole.

TM: These are really valid concerns. Ego development (and Kegan's MM system) is what I call a "wide" developmental line – Loevinger called it a "holistic" construct, in contrast with the narrower lines or constructs of other theories. It is an ongoing issue RE whether wide lines are legit. The MM (ego) developmental construct overlaps with, i.e. includes or correlates with, many other constructs or "lines," including spiritual intelligence, reflective abstraction, leadership maturity, social-emotional skill, self-control, self-understanding, etc.[5]

In one sense, the argument can be answered statistically/psychometrically. The ego development measurement has shown itself to grow "as a whole." When looking for component sub-lines in ego development data of large(ish) populations, there is a consistent finding of no sub-lines being found (in a factor/component analysis it "loads on a single factor" – as found repeatedly in studies). But that may not be a satisfactory answer because that type of analysis assumes that different subskills might be captured by different items in an assessment; but in a sentence completion test all of the items tend to be looking for the same things; or better said, the scoring method scores them all the same way (in all MM theories). The scoring methods in STAGES don't ask the scorer to note specific sub-skills (though it allows for, but does not require, recording the

---

[5] More on that topic in Murray (2017) **here** in sections "On multiple intelligences and wide vs. narrow skills" and "One skill to rule them all – is ego development one thing?"

"quadrant" – I, we, it, its – of the text). So the data does not exist to factor out the subskills, and it would probably be expensive to re-score (though possible and a valuable study).

Loevinger takes the assumption that there is "master trait" of "personality…a holistic process, a striving for meaning and self-consistency over time," (a habitual organizing frame of reference) "[that] involves many dimensions of personality development"[6]. Even among Loevinger's followers there is controversy about whether it is one underlying capacity or a collection of sub-capacities.

So a big question in the developmental field is whether specifying narrow vs. wide skills/lines has construct validity or "ecological validity" – i.e. whether they can be said to really exist in a form that can be measured. The HCT theorists would critique ego development as a super vague fuzzy construct--something one can't really even define in a short space. This has been used to argue that wide lines are not valid. But I think I can use HCT to argue *for* (some) wide lines in the following way (as I have done in Murray, 2017).

Fischer and Commons are clear that any developmental "skill" must be defined in relation to a *real task.* I have argued in some of my papers (Murray, 2019) that you can't find real life tasks that just use, say, "abstraction" or "creative thinking" but that these sub-skills are always *an inseparable part* of real tasks (like parenting, doing good at work, making friends, etc.), so HCT actually predicts that when real-life has only wide-*tasks* its just as hard to measure narrow skills as wide *skills*. When the sub-skills are massively interacting, you can't "see" them individually. One can invent separate constructs like "critical thinking" and "creativity" and create a test, a fake task, to measure them, and then look for correlations between those constructs. But do those constructs really exist? Playing a musical instrument, or playing sports, or foraging for food, or finding a mate, are real tasks they hardly overlap as tasks, so you can define and measure real solid independent skills based on them. But there is no "self-understanding" *task*, rather self-understanding is an abstract construct we can see used across many real life tasks. Some would say, "that construct exists for many tasks so its a 'general higher order skill'! – that should make it very important and also easier to measure." But my reading of HCT implies that you can't infer in that direction – you can only define the complexity of a task, and the skill is the ability to do that task.

I am unsure about all this though. If one can identify a generic sub-skill (or micro-skill) that is a component of many tasks and super-skills, it seems important to study and measure it. I'm just not sure if all such skills are arbitrary abstract inventions unconnected with underlying cognitive mechanisms (brain studies might help answer that). Ego development is one such made-up construct of course – a "wide" one. What I am wondering about is whether the narrower ones are actually taking one *further* from reality into speculation, even though they seem to be honing in more closely to the underlying mechanisms. Like Ptolemy's epicycles, one can use abstract reasoning to find detailed patterns that explain phenomena, but which are not actually related to causal mechanisms.

---

[6] From p. 229 of Jespersen et al. (2013).

Actually, it could be argued that STAGES, in contrast with Loevinger and Cook-Greuter's models, is not at all fuzzy in defining the construct. For Loevinger and Cook-Greuter the stage definitions, in a sense, change with each level. *Something* grows, but what that is cannot be clearly defined in those models. STAGES "defines" each stage simply using three parameters. But still, determining the value of each of those 3 parameters requires a detailed scoring manual and a year of training. You can say each stage can be given a concise definition using the three parameters, but to *operationally* define each of the three parameters (in a specific way) is pretty complex (so it kicks the can to the next level down).

No one is claiming that all of human psychological maturity or cognitive complexity can be captured in one assessment or model (though the neo-Piagetian theorist do claim that all cognitive development can be captured by one mechanism and structural logic). And of course we all acknowledge that it is absurd and dangerous to assume that any person can be well described with one measurement or category. MM, as described by Kegan and the Loevinger tradition, seems to make a lot of sense to a lot of people, so I think if one had to pick just one measurement, MM would be adequate. But if we were going to assess multiple things, what should we include? As you know, there are so many assessments and constructs out there in academia. Do you have ideas for what would work better?

TJ: RE: "HCT implies that you can't infer in that direction – you can only define the complexity of a task, and the skill is the ability to do that task" – this deals with very interesting issues that would warrant a thorough scrutiny. I believe you are on to something valid, that there are indeed some "general" tasks that have wide and pervasive implications for how a person makes sense of him-/herself and the (social) world.

Regarding your final point, I think there is a lot of empirical research to do. In my 2018 Integral Review paper, I argue that there are several quite distinct components of adult development that don't necessarily walk in step on a developmental stairs. I briefly describe cognitive complexity, complexity awareness, construct awareness, perspective awareness, self-awareness, meta-awareness and the phenomenon of spiritual awakening. It is an empirical question to what extent the developmental patterns of these components are closely correlated or not. My concerns regarding ego development frameworks is that they seem to assume that there is a single developmental trajectory, and I believe this to be misleading, or at least not proven.

I think in the paper I make a good argument that such competencies can develop quite independently. My argument is not based on empirical research results, because we don't have much of that yet, but describes types of people that have various mixes (weak and strong) of these skills.

Do you agree that it can be an unproductive or misleading thing to try to pack all of these types of capacities into one developmental line?

TM: Yes, it can be. Professionals who use MM assessments are (usually) careful to make sure they are not abused to label people into categories and make high-staked decisions (like hiring/firing). The intent is to use them to support self-reflection and mutual understanding (at individual and team levels). If used well, nobody is forced to agree with their scoring – they are taught about developmental levels and invited to reflect upon how their own strengths and challenges line up with the sequence of growth the theory describes. Anecdotal evidence is that most people feel quite "seen" and gain some insight when coaches/consultants use these assessments. But I'm sure there are counter-cases to that. But in working "on the ground" with people I expect that that many people would be confused if they were shown the results of 3 or 4 tests that then had to be coordinated in some complex way by the coach/consultant.

MM frameworks, like the one presented in Kegan's "In Over Our Heads", seem to add so much to our general understanding of the human condition, by just getting people to think about the developmental dimension. People naturally want to place themselves at some chapter in this story of human growth. On the other hand, we both know of the dangers and overshoots of consultants and pundits overgeneralizing based on these models.

Is that a fair description of the trade-offs?

TJ: A similar argument could be made (with some justification) for personality typologies, such as the Myers-Briggs Type Indicator, the Enneagram types, or even astrology. They can scaffold a process of self-reflection and insight. But that is a rather different thing than claiming the model in question adequately represent how people actually work. My main interest here is in the *science* of figuring out what *late* stage development really is (and isn't). Our world needs more wisdom, cognitive complexity, compassion, and perspective taking – we need to better understand what these things are and how to support them.

I still believe that it makes sense to be careful about collapsing increasing complexity/increasing abstraction of concepts with witnessing capabilities into one stage sequence. At least I believe that when operating with models like the STAGES framework, you should take care to point out that people in real life vary far more in those different dimensions than can be represented using single line stage models.

Are you arguing that from a *theoretical* perspective, it is defensible to lump together the different lines or components of development?

TM: Good, we can separate the pragmatics of assessment for coaching and organizational development from assessment for more rigorous and scientific inquiry into human potentials (understanding that there will be some overlap between them).

Any theory that uses simple categories or linear sequencing to describe the human condition is problematic. And one can always break up a phenomenon into sub-phenomena, ad-infinitum. E.g. one can define 8 elements of "reason" or "wisdom" – let's say one is "perspective taking." Then you can find a theorist who has broken perspective taking into 5 more facets (in both theory and measurement); and for each one of those facets you can probably find another who has broken it down even finer. All of these conceptual "cuts" are rather arbitrary, and have fuzzy overlap, and there are diminishing returns with increasing specificity in the "human sciences." Often, the more specific the skill, the more artificial is the assessment task or instrument assessing it. So the question becomes pragmatic as well as theoretical: what is the appropriate level of granularity for any purpose?

These subskills are hard to define precisely because they seem to overlap (as constructs) and influence each other (as processes) – e.g. "critical thinking" has significant overlap with "self reflection" – we can create separate tests for each of these but are they really such separate skills "in the brain" (or in behavior)? – or better, *to what degree* are they separate? MM theories (Loevinger and Kegan) make the assumption that a bunch of these sub-skills are so tightly interrelated that they *tend on average* to grow together and form a kind of gestalt phenomena (while obviously per individual there are differences in how they track with each other). I am pretty sure that this hypothesis will not be "proven right or wrong" but rather we can (and should) empirically determine *how much* the factors correlate and influence each other. This is your question I believe, and it deserves empirical study. But in addition to whatever the empirical findings say, one still must grapple with the ontological question of whether and how the constructs are actually separate processes or human attempts to break up a continuous field of phenomena into arbitrary chunks.

In terms of your list of six high level capacities (I had to go back to your article to refresh my memory) – in theory I like the idea of breaking it down to look at sub-components, but there seems to be a lot of possible overlap and cross-influence in these six categories. The question of whether sub-skills are separate-but-correlated, or whether one can be described as a "component" of another, is really hard to answer (this is related to ego development having a much less than 0.5 correlation with IQ – see Cohn & Westenberg, (2004); but here brain science might help answer the question).

It would take some work to get to a place where your constructs were well-defined as fairly independent skills, which then had a measurement protocol for (or all or any subset of the six). Loevinger struggled with this in coming up with what she eventually called the "master trait" of ego development. This is how Manners describes it: "an increasingly complex synthesis of impulse control, conscious preoccupations, cognitive complexity, and interpersonal style" – a list to which others have added: motives for behavior, moral reasoning, character development, and self-concept. Wow, what a long list of diverse skills. Its amazing that anyone tried to combine them into one construct and "got away with it" – yet 100's of studies have indicated that the construct is sound psychometrically.

TJ: Up to mid-postconventional, yes ... Still, my questioning concerns the highest stages, and I argue that it is completely misleading to correlate Commons paradigmatic and cross-paradigmatic stages with the (half hypothetical) very highest stages of ego development.

TM: Ah, yes – sorry I was not clear on this earlier. Though you will see these correlation tables mapping one theory to another (Loevinger, Commons, Fischer, Kegan, Wilber, Aurobindo, Piaget, Graves, Kohlberg, etc.) in countless papers in our community, they are mostly misleading, especially those that map a MM model to a CC model. Theories of CC are more valid in this mapping, as they are trying to measure the CC alone of various constructs, which is a central aspect of them, but, I would argue, does not capture the entire phenomenon. The discovery that CC is a rigorous and valid metric for all of them is very important, but some make the mistake of assuming it explains the entire phenomenon. Those in the Loevinger tradition (including papers by Susanne, Terri, and I) do include these types of concordance tables, which is misleading – you are right. They basically say that the CC *aspect* of MM maps as indicated. As described above, one can have a horizontal "spin out" and increase CC without increasing MM, so Terri is explicitly saying that they don't map completely, and diverge in this way. We do have some evidence that Metaware meaning-making includes 4.5/Strategist cognition (within the STAGES model), but we don't have much evidence on whether Metaware (5.0...6.5) meaning-making includes "12. single principles" or "13. paradigmatic" cognition. I agree with your suspicion that they may not correlate well, but am not sure what Terri would say.

Maybe it is just that all of these sub-components are so tightly interwoven that one could have taken any of them as the master trait and get the same type of results – I doubt it would work as well but it is possible. Here I think we bump up against the leading edge of science methodology. The traditional (i.e. "modern" 3rd PP) scientific paradigm is to separate things into their components and then see how they correlate, as if they were separate but related. But can they really be separated? Again are the parts things we make up arbitrarily? Like you can describe any color using the RGB system or the CMYK system – neither can lay claim to being the "right" way to break it up into independent dimensions. In the hard sciences "complexity science" (what I would call 4thPP science) has been able to work better with emergent non-linear patterns. For psychological sciences I think complexity is largely used just as a metaphor (though in social sciences "social network analysis" does produce quantitative results).

I am not sure: what is gained and lost from trying to measure each of the component constructs separately, and from moving away from using a holistic construct? As you know, researchers have done these comparisons with many of the psychological constructs we have assessments for. It's a lot of work and it adds *something* to our understanding of ego development (and the other constructs), but my take is that few if any of these studies yielded results that changed how people (still) understand ego development.

Also, one thing that is exasperating about defining ego development, from a measurement perspective, is that the basis for describing it keeps changing with each level. For example, at the lower levels it includes "impulse control," but the relevance of that part fades away in differentiating later levels. Ego (or MM) development is what is seen to *emerge* as people mature (get wiser with experience). You can't predict what the next level (or branching set of emergent phenomena) would look like based only on the qualities of the prior levels (that is one definition of emergence – e.g. you can't predict the properties of water/H_2O based on the properties of H and O). We *can* predict that it will be more complex and nuanced, etc., but not the observable psychological phenomena are emergent.

You are concerned with the later levels, do you think my argument applies for them?

D. Complexity vs. Witnessing; States vs. Stages; and the Logic of Development

TJ: RE "the basis for describing it keeps changing with each level" – I think that is a good and significant point. Common's uses the same "rule" for moving to each level. Fischer changes the type of object with each tier, so that is somewhat similar. But you are right, in Loevinger's system at least, there is no transition rule that specifies how each stage goes to the next.

Anyways, you may be making things more complex than is needed Tom. I agree that my six capacities would need a bit of work to be turned into solid theory or science (some of them should overlap, but others should be more independent). But, to repeat from my prior email "I still believe that it makes sense to avoid collapsing increasing complexity/increasing abstraction of concepts with witnessing capabilities into one stage sequence, in favor of allowing for different combinations of different dimensions of development/awareness."

I think the transpersonal stages cannot be explained by increasing complexity and levels of abstraction of mental representations. There is a quite different dimension of development that has to do with noticing internal processes and gradually disidentfying with the thoughts, emotions, desires and other goings-on in the mind and the body, giving rise to an increasingly strong capability for witnessing.

What if we just focus on those two aspects? Do you, or does Terri, think that they can be lumped together?

TM: OK, I may have gone off the deep end there RE the wide lines :-). I share your intuition that there seems to be two separate things going on there at the higher levels (Terri's Metaware tier), something related to complexity and something related to something more spiritual or transpersonal. First, what I can say from experience is that I have been at gatherings of people most of whom scored in the STAGES Metaware tier, and I would have to say there really was something palpable about the "ego development" (including an extra nice sense of humility and humor), but, though they were all pretty intelligent and nuanced, there were a lot of people there who had not developed (and maybe were not interested in developing) the abstraction skills it takes to understand really obscure philosophical discussions, write academic papers or rigorous scientific explanations, or design a large scale systemic change in an organization. I think a group of people who score high on "paradigmatic thinking" in the HCT model would feel very different to be with vs. this group (with, maybe 30-50% overlap). I might learn more and be more intellectually impressed with such a group, but probably would not enjoy myself as much and fall in love with them all as easily.

Terri has assessed many people with advanced spiritual practices and stages. She also finds that ego development is relatively independent of all that spiritual stuff, and that it captures the complexity *with which* someone understands what is revealed by those spiritual/contemplative experiences pretty accurately. The assessment does not put those advanced state-stages at the top – it puts a certain sophistication of one's *interpretation* (meaning making) of them is at the top. There are many ways to interpret the "no self" experience, and only certain ways will rate in the Metaware tier. Same with the emptiness of conceptual meanings, emptiness of time, or space, etc. The assessment (and theory) do not measure the state-stages, but the theory does say that having certain state stages is a prerequisite for Metaware stages. I think there is some interesting research that could be done to try to prove this – its just a hypothesis at this time (Terri's paper in this issue says more about the theory).

Also Terri's theory of *States* is related here. We understand from the Wilber-Combs principle that one can experience states associated with "awakening" at any of the developmental levels. Terri asserts (it's not always clear whether Wilber agrees) that certain stable state experiences are *necessary but not sufficient* for solidifying certain stages of development. State here seems related to modes of *perception*, like "metacognition" or "awareness of awareness." But Terri extends the concept of state-stage (or view) down earlier than the usual "spiritual" associations, to include things like holding focused attention, and hypothetical thinking (fully controlled internalized perceptions, free of memory) as state-stages.[7] Relating it to what I said above about exteriors before interiors, it could be that the "necessary" is about purely cognitive ability, like witnessing, but to be "sufficient" to create ego development the awareness has to be applied to deconstructing and understanding the self. The findings you mention in your paper about the "Mysticism Scale" not correlating with ego development measures fits right into this extended interpretation of the Wilber-Combs principle.

TJ: Well, this is all very interesting. I believe it can be fruitful to consider the relationships between increasing capacity for dispassionately witnessing internal processes, gaining a more complex understanding of causality regarding those processes and the role of shadow aspects in ego development. However, that seems to be a whole new area of exploration. I am still questioning if it isn't potentially problematic to operate with a one-line sequential stage framework in the more sophisticated forms of adult development.

I.e. the question that is prominent for me is that if the Stages framework really captures a developmental sequence, what is the logic that explains that the Metaware tier requires having mastered the Subtle tier first? Any thoughts about that? As I have said before, in

---

[7] This topic is covered in more detail in two articles in this special issue, one by O'Fallon on stages and stages; and the other by Churchill and Murray, on Indo-Tibetan contemplative practices.

Fischer's and Dawson's frameworks, there is clear intelligible *logic* in the sequence of the tiers, each new tier representing a higher level of abstraction by creating mental constructs that condense complexity into higher-order concepts. It still seems to me that the Metaware objects you talk about are not concepts that represent very complex relations among concepts on the preceding levels.

Also, I would be interested to hear your comments on the late stage awareness profiles I sketch in the 2018 IR article (see section "Five Prototypical Late-stage Awareness Profiles"), in particular regarding person D and E. Do you think that such profiles exist? If yes, how could they be expected to show up in a SCT and in relation to the STAGES stages?

TM: Referring back to what I said above on wide lines (and the link to more discussion). Maybe the two of us could come up with a list of pros and cons of wide (all-encompassing) vs. narrow (multi-) lined approaches. There are a bunch of tradeoffs I think, in terms of (a) comprehensibility/usability; and (b) ability to demonstrate validity.

But, RE the logic of ego development, tying together several points I've come to, I said there were two necessary but not sufficient conditions for ego development into any level: the requisite complexity capacity and the requisite stable stage-stage. It *might* be that these two *together* are sufficient. Hmmm...as I think of it I would propose that if we include a third thing that would cover the whole picture (maybe): the *unlearning* part. So I'm thinking that ego development requires (1) the stage-stage to have awareness into a certain depth of the self; (2) the complexity capacity to comprehend patterns at that level; and (3) the application of that awareness and complexity to unlearn whatever stands in the way of progressing at any given fulcrum. (Oooh – I will have to put this in the paper I am working on with Churchill in this issue!)

So, in terms of whether a wide/holistic/single line is a good idea, we could ask what is *lost* by using a model with one holistic line? Referring to the three things I just proposed as prerequisites for ego development, we could say that what ego development *assessment* misses is that it does not register: (1) state-stage achievement without the other two parts – i.e. spiritual realization without ego development (maybe called the "spiritual enthusiast"!); (2) complexity capacity by itself – i.e. the horizontal spin-outs; and (3) late stage narcissism – one who has spiritual realizations, and the cognitive complexity for deep understanding of what is revealed there, but has not *applied* it to deconstructing enough of the self (such a person uses his capacities to evaluate and manipulate others). We might say that ego development construct is *defined* as a combination of the three things, so it does not measure growth that does not combine all three. (This is only partially true as, the STAGES assessment at least, the assessment final score value may miss these things but the human process of assessing the sentence completions and preparing a personal analysis does note some of these nuances, such as spin-outs).

RE your question about the profile sketches of person D and E in our paper – I will copy that here:

Table 1. Profile sketches.

	Cognitive complexity	Perspective awareness	Construct awareness	Self-awareness	Pure aware-ness self
Person D	Weak	Weak	Weak	Strong	Moderate
Person E	Weak	Weak	Strong	Moderate	Strong

I will have to think about this more, but I think my analysis above of the spiritual enthusiast, the 4.5 spin-out, and the late stage narcissist is close. The first and last have weak CC and perspectival awareness; the first has strong pure-awareness. One thing we have not touched on much is the difference between the aware-ness of awareness and construct awareness aspects of 5th PP. Terri would have more to say on this I am sure.

But I think those three things above define what you call the "logic" of the ego development sequence. The simplicity of the logic behind HCTs is either misleading because, as I said, it does not differentiate different types of meta-moves, or, in some cases it implicitly uses a limited type of meta-move which is rather cognitive (CC) and thus would not capture all of what is going on in ego development.

I would have to think about this more, but, given what I said above, it may be possible to specify the types of meta-moves involved in ego (MM) development: (1) Witnessing, or any awareness that perceives a deeper aspect of self; (2) reflective abstraction or subject-object move which uses complexity capacity to see how the now-seen part fits/operates within the self as a system; (3) a releasing ("emptiness") move (Bonnie Roy would call it "insight generation") that unlearns an old assumption to allow for new emergent understanding of the self-system (and thus a new understanding of self/other/world).

What is not worked out here (but see the other papers in this issue by O'Fallon and Churchill) is specifically *what* is witnessed, comprehended, and released at *each* developmental fulcrum. Also, the STAGES scoring method could be enhanced to more explicitly pull out separate sub-indices for these moves – witnessing, CC, and unlearning – or any of the other sub-skills like the ones you mention in your paper.

I would guess that move #1 is related to "quieting down" and "witnessing" in your words, and your "disidentifying" maps to the third part – what do you think?

E. Skipping Stages and Meta-move Types

TJ: I think in part what you are saying is that there is a lot in the STAGES theory that is not directly related to, or assessable by, the STAGES assessment. I think the difference between what is proven, or even provable in theory, should be clarified in the descriptions of STAGES. I am also interested in pinpointing what descriptions are really supported by empirical evidence of any type, and what statements are more intuitive or speculative. And I am really more interested in qualitative data than quantitative, even though the latter is important for stringency and reliability.

As you know from previous exchanges we have had (and my 2018 IR article), one of the questions I have is whether the model adheres to the idea that no stage can be skipped, following the principle common in ego development models. This seems to be what warrants your Metaware stages being stacked on top of the Strategist stage. Has this hypothesis been proven?

TM: Hmm ... for me the issue of skipping stages is more complicated than it seems at first glance.[8] HCT specifies that the next level comes from *any* operator that operates on one level to coordinate the prior level into an emergent next level. But there are many possible meta-moves for building one hierarchical layer upon another, and it seems that HCT is mute on which ones are involved in any application. The subject-to-object move is one; synthesis is another, abstraction is another, witnessing may be another meta-move. The way HCT is usually used (e.g. in Lectica assessments) I think there is an unexamined assumption that sticks with a certain type of meta (hierarchical) move (reflective abstraction), even though they portray it as covering all possible types of hierarchical moves. I think a lot of people in our community confuse that with the specific, and most popular, evaluations used by Dawson and colleagues at Lectica, which are specific instantiations of MHC for specific (task) domains. I.e. they don't measure "hierarchical complexity" they measure it *in* some area.

IMHO though Lectica folks say they are measuring "hierarchical complexity" in the actual practice of their better-known assessment tools they are measuring a specific cluster of meta-moves, all of them related to the single concept (meta-move) of "reflective abstraction." Fischer's and Common's theories can account for *any* type of meta-move, but the Lectica assessments we are familiar with measure a small cluster of moves. Lectica actually combines two meta-moves: the conceptual abstraction of the object, and the structural complexity of the idea (single>mappings>systems). Note that Lectica *can and has* built assessments that measure other meta-moves, like the hierarchical moves in learning ever more complex math or science. Here is another example, put yourself in a room of people scoring at the "paradigmatic" level in mathematical theory, and see if they seem overall extremely "mature."

RE the above idea of horizontal spin-outs, but they are only "horizontal" from the perspective of the ego development model! From a strictly cognitive model, things just keep getting higher in complexity – its not horizontal, its vertical, and the ego-developmental move of applying a given cognitive capacity to the domain of ego-involvement may seem a *horizontal* move! (See my IEC 2018 slides.)

One can imagine that if one kept to a single type of move as constant then you would have a very clearly defined hierarchical sequence. Stages could not be skipped, because each level builds upon the prior, by definition. But if one's developmental model incorporates several types of moves then its more complicated. From level X of complexity you can get to level X+1 by making moves A or B or C, and by the time you get to level X+3, is there a risk that you are comparing apples to oranges? This is the case if you are comparing just cognitive complexity at level X with ego development at level X.

---

[8] This next part is something I presented in my IEC conference talk in 2018.

But regarding the question of whether "no stage can be skipped" – I addressed it from a theoretical (or construct aware) perspective, but it can also be addressed empirically for the STAGES model. I will send a draft of the paper going in this special issue, titled "Summary of STAGES validation research." In it we mention a longitudinal study that seems to show that the metaware stages do follow on top of the earlier levels.

TJ: You said above that "there are many ways to interpret the 'no self' experience, and only certain ways will rate in the Metaware tier." So, yes, but does the sophistication in interpreting the perception of awareness as such reflect a level of abstraction that builds upon (requires) and goes beyond the level of complexity at the Strategist level? – that is a core question for me.

TM: OK, and now I am also noticing that you wrote "Fischer's and Dawson's frameworks, there is clear intelligible logic in the sequence of the tiers, each new tier representing a higher level of abstraction by creating mental constructs that condense complexity into higher-order concepts." So the concept of higher *abstraction* is important to your question. I will answer from my understanding (I wonder what Terri would say here – and also, I am in early phases of on a whole other paper just on the topic of "Abstraction and Metamodernism," and don't have these ideas fully baked yet).

As I said, HCT builds layer upon layer based simply on each level operating on or coordinating the prior level. Abstraction is only one such operation. Formal operational thought is sometimes defined as the combination of *abstract* thinking and *logical* thinking – which both come on line at 3.0 (3rd PP) in STAGES. Abstraction and logical complexity are defining moves through the whole Subtle tier, but starting with the Metaware tier a new type of awareness and object appear that is not defined by an abstraction move. The objects that emerge at each tier may be theoretically unpredictable based on the prior tier – this is the nature of emergence. E.g. given just matter you can't predict life, and given life you can't predict mind/culture – though you can always go back and *explain* how the later builds upon the prior, the emergent level is a kind of surprise.

The move into Metaware is an *emergence* move, not an *abstraction* move. Like the emergence of abstract thinking on top of concrete thinking, we can say that it is what is *observed* to happen, not what *must* happen. Our data shows that metaware thought does come after (e.g. 5thPP comes longitudinally after 4th PP); and Cook-Greuter's and Torbert's work has always included the idea that construct aware and unitive come after Strategist. I can try to explain *why/how* we think 5th PP builds on top of 4th PP, but I think our explanation of this is still forming (and not as good yet as the literature that explains how formal operations builds upon concrete operations).

Within 4th PP one increasingly builds deeper understanding of the parts of the psyche/mind, ideally including the embodied perceptual deepening as well as cognitive complexification. What emerges at Metaware is a coming together of the parts, as their relationships and interpenetrations are seen and deconstructed and integrated – into a new level of holistic apperception of the self. The witnessing state or "awareness of awareness" is also an awareness of all those parts of the self that are held *by* awareness, i.e. are *not* awareness (as awareness becomes object). If you don't do the emergence move, and keep going with abstraction, then you get the 4.5 spin-out, and this may be why HCT and STAGES seem to diverge at the Metaware tier. (Again, increasing abstraction beyond 4.5 levels may be an important *vertical* move for *some* models, but not for STAGES or ego development.)

I think that this happens at *each* tier – a new object emerges and then abstraction and complexity are the logic that build CC in that tier (first individuals then collective/systems) until the next tier emerges – which is an emergence move not an abstraction (or complexity) move. The idea of "simplicity on the other side of complexity" is *different* for conceptual/abstraction moves vs. for emergence moves (this is what I am working out in that new paper).

Anyways, we have opened up a lot of questions here. What would be some good next steps?

F. STAGES Empirical Studies and Longitudinal Analysis

TJ: I have now read the paper you sent me, with a good deal of interest, even though I am very weak on statistical analysis (and not so very interested either). I do think it is a very good thing that you and the statisticians you have worked with have critically examined the statistical properties of SCT testing and reviewed and developed the methodology for arriving at scores. The article will be a valuable contribution to the field in these respects. Having longitudinal data is indeed very significant. The analysis of the statistical properties of the test offers a number of valuable and corroborating conclusions, that’s fine.

As you can imagine, the major question marks I have about the Stages model are not addressed in the article (which was not to be expected given its purpose). Here is a somewhat different way of approaching what I have asked before.

Since I am not intuitively convinced that inhabiting the metaware stages, in the sense of being aware of and preoccupied with pure awareness, necessarily comes after one has mastered the late ”Subtle” stages (I don’t like the term subtle, hence the quotation marks), it would be helpful to know if people who are scored at Terri’s metaware stages always convincingly display evidence of being at home in the preceding stages. So what would be interesting, and would provide support for the Stages model’s assumption about a linear stage sequence, is, at its simplest, to see if everyone who scores at one of the Metaware stages also fulfills the requirements for being scored at stage 4.5 (and possibly 4.0). It would be of particular interest to look more closely into any cases of people who were scored at 5.0 or higher and who don’t fulfill requirements for stages 4.5 and 4.0, if such cases exist. I.e. if you (a collective you here) can report empirical evidence that people who get scored at Metaware stages have a significant number of *individual items* scored at the late ”subtle” tier, so that it is evident that the Metaware stages transcend *and include* the previous stages in a linear sequence.

My intuition is, as you know, that awareness of awareness is very weakly linked (if at all) to cognitive complexity, and that there are surely people who have a well-developed witnessing capability without having a very complex cognitive world. So, do 100% of the people who score at Metaware stages fulfill the requirements for stages 4.5 and 4.0? If a lower percentage, how low? If there are Metaware people who don’t fulfill requirements for stages 4.5 (or 4.0), what do their item distributions look like?

Ideally you would show this in relation to the scoring procedure, so that people who are deemed to be at Metaware stages have mastered the kind of cognitive complexity and levels of discourse abstraction characteristic of the later postconventional stages. I.e. if the assumption is that you only reach the Metaware stages after having matured into the Strategist stage, then I think it would make sense to include a rule in the scoring procedure that you only get a summary score on the Metaware stages if you also have a substantial number of individual items scored at the late Subtle stages.

TM: OK Thomas. This is a great idea. If there is time between doing all the other things I need to do for this issue, I will run this data analysis. If not soon, then later.

But I do have a guess. The paper I shared with you shows that scores tend to cluster around an average in a normal bell-curve distribution. If the average was at 5.0 then there would probably be a lot at 4.5 also. I will check. But the cutoff method to determine the final score (TPR or 'center of gravity') only looks at the top scores, which for the metaware tier is looking for only 4 scores at or above a level to say the person is at that level (Susanne uses a similar method). So given that, it is almost guaranteed that there will be many more scores below the "center of gravity" score (at 4.0 and 4.5). I think to answer your question I should also look at the percentages of scores at each later level (sort of like looking at the straight sum of scores and ignoring the cutoff method).

Also, in Table 4 of the Research Summary paper ("Longitudinal: Prior Scores vs. amount of change to next score") you can see the longitudinal transitions for all surveys, starting at each level, how many went up, stayed the same, or down for the next longitudinal test by how much. That gives some indication of your question, but this is all data at the survey level, and your question asks at the item level, which is a great idea.

TM: OK, I have done that analysis and here is a figure below. We would not have thought to do this if you did not ask your question, so thanks. Here is a chart showing, for protocols with center of gravity values (ogives) of 3.0 to 6.5, what percent of the 36 item scores are at each level.

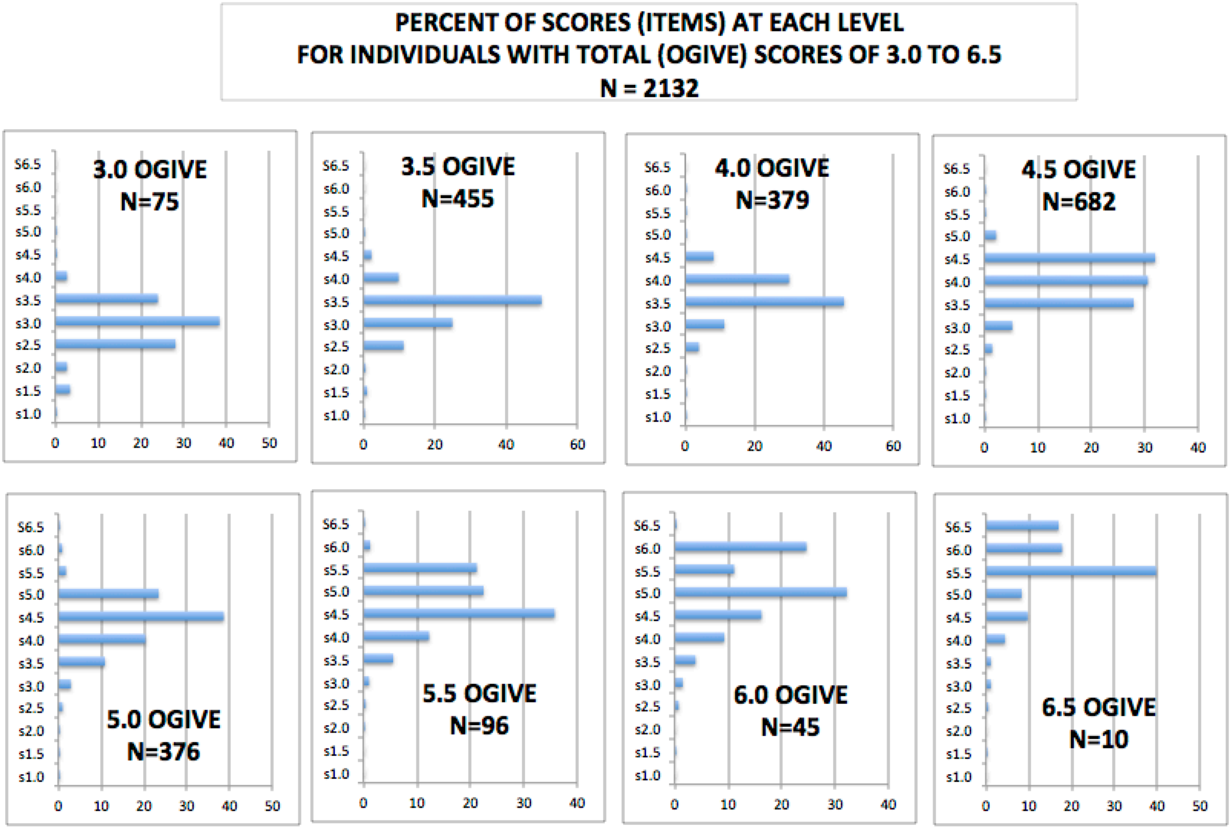

Figure 1. Ogive tables.

This is what I am noting:

You can see that for 5.0, 5.5, and 6.0 there are many scores at 4.5 (Strategist). (Recall that the ogive cutoff method prioritizes the higher scores, so the total score is not the average, and is often not the mode, i.e. top of the bell curve.)

However, the scores do tend to follow a normal distribution around the average, so at 6.0 and 6.5 there are naturally less and less in the Subtle tier.

The 6.5 graph by itself might seem to confirm your suspicion that the meta tier does not have many subtle tier scores, but (1) there are not as many scores there so its a weaker data point, and (2) as mentioned above, people tend to write close to their center of gravity or average, even if the have the capacity to write lower.

Recall that with each tier the type of object changes, so the complexity about that object can start again at low and build up from there – so there may actually be a kind of reduction in horizontal complexity starting at 5.0 (as in Fischer's model). (We are finding that in general the scoring system puts more in the X.5 (active) vs the X.0 (passive) scores. We think this is because people in passive phases have a harder time finding he words, and drop down to the prior level for content).

Compared to a normal distribution, 4.5 scores have a lot of 3.5 scores, 5.5 surveys have a lot of 4.5 scores, 6.0 surveys have a lot of 5.0 scores; and 6.5 surveys have a lot of 5.5 scores – this many indicate that for higher levels, a person with a active (X.5) center of gravity uses more active language in general (and vice versa for passive (X.0)).

But overall this should answer your question. Scores in the metaware tier (at least 5.0, 5.5, 6.0) have substantial scores in the subtle tier, and in particular a substantial number of scores at 4.5/Strategist, which tend to have complex language.

TJ: Thanks so much Tom. These are important data if you want to strengthen the plausibility of the linear sequence. So it is a valuable addition to us outsiders knowledge about what results you are getting. It would also be interesting to know if there are protocols scored at 5.5 or higher with no or almost no items scored at 4.5 (and 4.0). The pattern for the few 6.5 individuals is curious. For those of us who are interested in the highest stages, it would be a good thing to look more closely into the meaning-making worlds of people scored at 6.5 and 6.0, both in terms of looking at the actual responses as whole protocols, and, of course, to talk to them (interview) about a whole range of matters, and get a sense of how they navigate life. There are of course confidentiality issues here, and also problematic, from a scientific point of view, that the number of individuals is small.

G. Qualitative Analysis and Digging Deeper in Future

TM: Yes, I think this points really well at possible next steps we could explore in the next year or two. Most of the study's we have done with STAGES are statistical and look at averages and numbers; including comparison with another framework (Susanne's MAP). Terri has written a lot about the qualitative patterns seen within the inventories, but more could be done at the text level to compare with other models. For example, Terri is scoring children's protocols now and separating out different patterns and themes she sees. (See that paper in this special issue). More could be done actually to look at the *outliers* – the text that does not fit the norm, for instance "spin out" text that would score late in HCT but not reach Metaware in STAGES, or vice versa. We could learn a lot from that type of analysis.

Also, I just noticed you said "I am really more interested in *qualitative* data than quantitative" analysis. So maybe what we can do is share some of the actual sentence completions of people who are outliers (vs. the figure above) in that they have a lot of metaware scores but *not* many 4.0 or 4.5 scores. We can all think together about what this means. How does that sound?

There is a lot that is not shown in the "score." The total inventory score hides the pattern of levels (the histogram) over the 36 stems, and the score of each stem hides a lot of what goes on inside the completion. STAGES scoring looks at the level of complexity for the *most* abstract/subtle object in the sentence completion. Some completions are one or more paragraphs long. A 5.0 completion person may include some complex language about subtle tier objects, and then some simple or passive (receptive) language about a metaware object – the metaware phrase trumps the subtle phrases. If the metaware object is spoken of in more active/agentic/complex language then the score goes up to 5.5. But at any rate, the 4th PP activity in the completion is hidden from the score.

TJ: That is certainly interesting and would be informative. What I mean with qualitative is more in the line of doing something like Kegan's subject-object interviews with people, in order to get the opportunity to get much richer accounts of how people who score at certain stages experience themselves, relate to emotional and cognitive dynamics, react and act in social interactions, how they function in work and life, etc. I have not been in a position to thoroughly scrutinize Terri's stage descriptions for the Metaware stages and compare those descriptions to what I know from elsewhere. I think there is a lot of work to do before we can get a more grounded sense of the status of those stage descriptions in relation to real people's meaning-making patterns, subject-object balances and ways of navigating social relationships.

Also, as side comment, while I have it in mind, not directly related to this: I have not had time to really look up how different Terri's stage description of 4.5 Strategist is from Torbert's description of the Strategist (E8). I would guess that there are significant differences, not least related to what status is given to cognitive complexity and what I would like to call "context awareness." This relates to the general question if it makes sense to see the Strategist stage as something that has to be inhabited before one can develop the Metaware stages.

But let’s try to put this thing to rest for now!

TM: OK Thomas! This points to some rich inquiry possible going forward, especially in looking into specific examples of text – and maybe comparing how outliers would be scored by different systems. There would have to be a special agreement with Stages International on looking at specific text, as our agreement with subjects is that specific text examples are analyzed in-house and not shared publicly. But another option we have used is to combine elements of several responses to create generic examples that don't reflect the text on anyone in particular. It would also be interesting to separate out the different aspects of a given level within text, such as the abstraction vs logical moves in the Subtle Tier; or the awareness vs construct aware moves at 5thPP – I think much of this comes down to the STAGES scoring of early vs late *within* a level, which has not been written about much yet. Also, I mentioned the aspects of text that are "lost" in the numerical scoring, that could be re-analyzed.

Note that subsequent to this email exchange, Thomas and Terri O'Fallon had a videoconference conversation about her model, which has been transcribed and is available at: http://www.perspectus.se/tj/ConversationOFallonJordan.pdf

Jonathan Reams[1]

Welcome to this issue of Integral Review (IR)! We are pleased to welcome you to a new regular issue, which brings together a number of interesting articles, essays and a number of reviews.

It has been two years since our last regular issue of Integral Review in August of 2018. While we have been pleased to be engaged with and publish two special issues since then, (one on post metaphysical spirituality (link here) and another on the STAGES model (link here)) we are always excited when we are able to pull together a new regular issue. These issues are a long journey, through many different kinds of processes for the authors, reviewers and editors involved. Despite these differences, all of the contributions in this issue can be perceived as forms of advancing our understanding of an integral view of the world and our participation in it. There is a nice mix of themes explored, from adult development in many forms and uses through various forms of engagement with the world to leadership.

I find myself in a privileged position as editor-in-chief, in that I am able to not only enjoy the final products of the authors, but am also able to learn things between the lines as I observe and engage with the journey they go through as critical perspectives come from reviewers, ideas get refined and clarifications emerge. The enrichment that comes from this process has been invaluable to me over the past 15 years in this position and I am grateful for the learning that comes with the role and work. It is my wish that you can extract as much of the depths of knowledge and experience our authors share as I have.

Our peer reviewed section for this issue contains three articles. We begin with Thomas Jordan's *Scaffolding Developmental Transformation Among Immigrants in Order to Facilitate Self-Directed Integration: Practices and Theories of Change,* which presents research from a study of six Swedish programs designed to help immigrants in their process of integrating into Swedish society. Jordan focuses on understanding what implicit and or explicit theories of change are behind the design of these programs and analyzes these through the lenses of various adult development frameworks. In addition, he examines the practices used in these programs to produce and inventory of such resources that can be utilized by other practitioners. This research provides clear ideas about how development can be scaffolded in this particular context based on these examples of current practice. Jordan does not attempt to evaluate the effectiveness of the practices used, but can point to a set of "promising practices" that, along with his analysis of the theories behind them, can help researchers and practitioners further develop this field.

Tom Bohinc, Jonathan Reams and Richard Claydon follow with *The Prometheus Leadership Commons: A Meta-Framework for Leadership and Leadership Development*. This article is the result of an initiative to address key emerging issues in the field of leadership development; professionalizing leadership and helping leaders, leadership development specialists, researchers and others navigate the plethora of ideas and approaches around how to lead. Through a grounded theory inspired process, a group of researchers and practitioners developed a meta-framework aimed at addressing these issues. The authors describe this process, along with a selection of conceptual contexts used, and then present the resulting framework (the meta becomes burdensome eventually so is dropped) with layers of illustrations and examples to show how it can be used. The discussion addresses key issues involved in a project of this scope and helps to position the framework in relation to various aspects of related discourse. A set of recommendations for ongoing work based on the foundation this framework provides are also presented.

Ben Bjorgaard takes us on a deep dive into *Stage Models of Adult Development: A Critical Introduction to Concepts, Debates, and Future Directions.* Bjorgaard provides an overview of concepts related to the evaluation of stage models, goes into key distinctions, looks at issues related to models and metrics as well as the constructs themselves. He also examines the move beyond developmental psychology into relational developmental science. Bjorgaard lays all this out in relation to his perception of a need to evolve the hard science around generalizable measurement and related philosophical advances related to ongoing synthesis and contextual application.

Our editorially reviewed section contains a rich collection of articles touching on a diverse range of topics. We begin with John E. Thomas, Thomas P. Seager, Thomas J. Murray and Scott Cloutier's *Being Prepared to be Unprepared: Meaning Making is Critical for the Resilience of Critical Infrastructure Systems.* The article dives into the importance of applying growth in complexity of meaning making to the field of infrastructure systems. We all rely on infrastructure systems in everyday life and enabling resilience in such systems has come more into focus recently. The authors examine the intersection of human and technological systems and bring to the foreground that these highly complex systems require adequately complex meaning making from decision makers.

Amiel Handelsman brings together two worlds of discourse and practice that seldom meet; Immunity to Change and the Enneagram. In *Nine Paths of Growth: Integrating Immunity to Change with the Enneagram* he brings together his many years of practice in both fields and how he sees practical advantages in making more explicit links between them. This article provides us not only introductions into both fields, but Handelsman's lovely touch to the process of showing us three different ways we can mesh these two models and processes to gain greater effectiveness in our work helping people uncover and address underlying beliefs.

Bill Torbert and Aftab Erfan have written up a piece that began with some online conversations, *Possible Mistakes of Late Action-Logic Actors in a Polarized World.* In this playful exploration of the topic, they help us reflect on the lesser focused on side of development. While there is plenty of research and reports on the benefits of moving into late or post conventional stages, there is much less on the potential shadow sides, or types of mistakes that can emerge at these later stages. Their exploration covers a dozen ways in which we can fall prey to the hubris of development.

Mark Shraga brings us a combination of subtle sensitivity with very embodied practice in *Aikido and the Pursuit of a Better Life.* He uses firsthand experience of how engaging in Aikido as a practice has enabled him to live a better life. He links the practice with theories or mind and then shows us how the very physical practices of Aikido have very subtle and powerful foundations and implications. From the simplicity of how to fall, to deepening our understanding of working with flows of energy and related concepts, Shraga illuminates a number of aspects of not only Aikido, but also of how we engage the world in general.

Frank Visser has engaged in laying out a clear and thorough set of critiques related to *Ken Wilber's Problematic Relationship to Science.* He examines Wilber's approach to evolution, carefully laying our Wilber's stance and claims for this. He then examines how various scientists describe evolution and uses this to as a lens to evaluate Wilber's approach to, claims and stance in this topic. He finds a number of places where Wilber presents what Visser shows as problematic claims for how science has failed and where Wilber claims support from, as well as superiority to, scientists' own approach to evolution.

Turning to how evolution is viewed from an empirical scientist, Marilyn Monk builds on her long and distinguished career of research in molecular biology to present *A Hierarchy of Consciousness from Atom to Cosmos.* In this essay, she lays out how, independent from the various philosophical or consciousness studies related approaches to evolution and based on her decades of empirical work, a clearly hierarchical model of consciousness became clear to her. While many are familiar with such models from Wilber or others, Monk describes how we can make the same claims without resorting to philosophical or other types of presuppositions.

We are pleased to be able to publish Jonathan Rowson's account of his encounter with Jordan Peterson, *An Epistemic Thunderstorm: What We Learned and Failed to Learn from Jordan Peterson's Rise to Fame.* This piece, originally written two years go as a way of processing his encounter with Peterson, re-engages this topic to not only help give us well elaborated points to consider as ways of sorting our own perceptions and possible impact from Jordan Peterson, but also helps lift the debate Peterson has stirred to a broader level about how we engage, respond to and most importantly, learn from such characters as they inevitably arise in popular society.

The final offering in the editorially reviewed section comes from Wendelin Küpers, who offers us a delightful and playful philosophical, even theatrical meta journey through time and perspective, with *Daring of Be(com)ing Wise: Perspectives on Embodied 'Sapere Aude' Enlightened for Today*. He sets the stage (literally) by contextualizing the Enlightenment urge for wisdom contained in all times and cultures and uses the admonition to 'dare to think' as a reference point. Once this stage is set, he introduces the scene containing a rich mix of those who have dared to think, starting with ancient Greeks and moving all the way to current times, giving voice to these thinkers in a dialogue format. This rich feast of conversation leaves us with an even richer set of questions to ponder going forward.

Finally, we have a rich set of book reviews in this issue. Elke Fein provides us with an extensive review of Hanzi Freinacht's *The Listening Society. A Metamodern Guide to Politics* to open this section. She begins with a comprehensive description of the contents of the book, enabling us to get a reasonably good understanding of the intent, scope and approach to Freinacht's ideas. Fein then delves deeper into some appreciative and critical perspectives on this work. This includes some stylistic or attitudinal components as well as questioning some of the more specific content claims being made especially in relation to the model Freinacht puts forward. In the end, we see that while Fein is not convinced that the idea of metamodern has been sufficiently distinguished from integral, it might still serve as a rallying point for a new generation of people eager to have a better foundation for their activism.

Verna DeLauer reviews *Loving water across religions: Contributions to an integral water ethic.* She introduces earlier work on a 'land ethic' that is now being applied to the topic of water and described how the author McAnally presents water as a social issue and invites us into considering our subjective experience of it rather than just the commodification or it as a natural resource. For this, DeLauer describes how McAnally explores how major religions have used water in their traditions and closes showing how contemplative practices can be used to deepen our appreciation for and relationship to water.

Marilyn Hamilton reviews *The Future Has Other Plans: Planning Holistically to Conserve Natural and Cultural Heritage.* She provides us with an extensive overview of the contents of the book, mixed with her own comments related to how the authors present the themes they explore. The extra time and work it takes to do this kind of holistic planning is seen to be more than worth the effort when it comes to the outcomes possible.

Shameeka Smalling reviews *The Body is Not an Apology: The Power of Radical Self-Love,* providing us with a window into an application of transformational reframing of issues, in this case, how our relationship with our own bodies can be transformed through the vehicle of radical self-love. TBINAA is not only a book but also a popular movement. Smalling provides us a succinct overview and commentary on the book and links it to her own experience and contemporary movements like transnational Black feminism.

We close with my own indulgence in the field of mysticism with a review of two books by IR author Doug Marmon: *The Hidden Teachings of Rumi* and *It Is What It Is. The Personal Discourses of Rumi*. Marmon has shown his ability to dig deep and go behind the prevailing views in his work on understanding quantum physics. In these two books, Marmon and colleagues apply the same principle to the works of Persian mystical poet and Sufi, Rumi. My interest in presenting this work to a broader audience stems from the impact it has had for me, deepening my appreciation for Rumi, but also deepening subtle aspects of my own practice.

It has been my and our pleasure as editors of Integral Review to bring together this collection of articles for your enjoyment, enrichment and even evolution of understanding. Hope you enjoy it!

Scaffolding Developmental Transformation Among Immigrants in Order to Facilitate Self-Directed Integration: Practices and Theories of Change

Thomas Jordan[1]

Abstract: This article reports findings from an empirical study of six Swedish programs using dialogue-based approaches to bridge gaps in views and norms, support relevant knowledge acquisition and support empowerment of immigrants who are still living on the margin of the Swedish society. The main purpose of the study was to investigate the program theories of the programs included in the study, with particular emphasis on their theories of change and practices used to scaffold developmental transformation of the meaning-making systems of immigrants. Several adult development frameworks and program theory provided the analytical framework for the study.

The analysis of the program theories of the six programs included in the study yielded an inventory of 72 practices used by all, most or some of the interviewed program leaders. A large share of these practices were regarded as very important in all or almost all of the six programs we studied. The inventory of practices can be regarded as a framework that can be used both by researchers in further investigations and by practitioners who want to reflect on and develop their skills and practices.

Keywords: Developmental transformation, dialogue, empowerment, immigrants, integration, refugees, scaffolding.

Introduction

This article reports findings from an empirical study of six Swedish programs using dialogue-based approaches to bridge gaps between immigrants and the majority society. The main purpose of the study was to investigate the program theories[2] of the programs included in the study, with particular emphasis on their theories of change and practices in relation to developmental transformation of immigrants from non-Western societies. The motivation for conducting the study was a belief that experienced program leaders have developed considerable skills in creating social processes that scaffold developmental transformations that are highly desirable for a number of reasons. However, most practitioners focus on doing, rather than theorizing about doing. Their know-how is therefore seldom articulated in ways that can be communicated to others. The lack of articulation of their program theories also means that it may be difficult to review, critically reflect on and develop the strategies, as the practitioners are embedded in certain patterns of meaning-making and may not look for potential alternatives.

The article is primarily devoted to presenting the practices and theories of change identified in the course of the analysis. It was not possible in the context of this relatively small research project to evaluate the effectiveness of the programs in terms of measuring the extent to which developmental transformations really happened among the participants in the programs. This is a significant and regrettable limitation of the study we made, but a range of methodological difficulties in measuring outcomes in these types of programs set restrictions to what could be done.

Framing

A significant share of immigrants (in particular refugees) to Western European countries grew up in societies with what the World Value Survey researchers call traditional and survival values (Inglehart & Baker, 2000; Inglehart & Welzel, 2005). Such value systems emphasize the roles of religion and family ties, deference to external authority, loyalty towards the own ethnic and faith community and distrust in relation to outgroups. In terms of Geert Hofstede's dimensions for cultural differences (Hofstede, Hofstede & Minkov, 2010), these cultures would be characterized as collectivist. The receiving societies are, according to the same researchers, in cultural terms very different: they emphasize secular-rational and individualistic values. Of course, "immigrants" are an extremely diverse category of people, even if delimited to certain nationalities, ethnic identities or religious beliefs. In focus here are immigrants who are to a large degree influenced by "traditional" norms and values and who lack experience with individualistic societies. "Traditional" societies do not provide scaffolding for development of the skills and values that are expected and often required in individualistic Western democracies. On the contrary, there may be a strong social pressure to conform to a rather restrictive set of norms, beliefs and roles, and strong discouragement of the development of independent meaning-making that diverges from the prevailing value system. In the terms of Western ego development theory, this could be interpreted as favoring early conventional meaning-making (however, see the critical objections to this interpretation discussed in Appendix 1[3]). An early conventional meaning-making system can enable a person to lead a productive and successful life as long as the received knowledge imparted during early life is fully adapted to the (stable) life conditions in the local society. However, migrating to a society with radically different ways of functioning, both regarding values, beliefs and norms, and regarding how social life operates (labor market, social insurance, educational system, other public institutions, etc.) means encountering a situation one has not been equipped to deal with.

---

[2] This term is explained in a later section.

The subtitle of Robert Kegan's book *In Over Our Heads* is *The Mental Demands of Modern Life* (Kegan, 1994). The book title refers to the challenges involved when a society expects and requires its members to function in ways that individuals may not have been developmentally prepared for. Kegan's premise is that the "modern" society makes more advanced "mental demands", in terms of his ego development theory, on individuals than earlier societies did. Kegan's perspective concerns, like other frameworks in the adult development field, *vertical* development, referring to a hierarchical conception of human development where more advanced skills and self constructions build upon earlier levels. It is common in the adult development field (see e.g. Kegan et al., 2001; Cook-Greuter, 2013) to distinguish between vertical and horizontal development, where the latter refers to learning and skill acquisition that does not involve developmental transformation of deeper-lying cognitive and self structures.

Immigrants have a lot of horizontal learning to do when starting to navigate life in the new country. They have to learn a new language and understand and interact with a range of societal institutions, such as authorities, social services, preschools, schools, health care and workplaces. The immigrant may encounter norms for appropriate social interaction that are quite different from the ones that were taken for granted in the home culture. However, immigrants may also meet challenges that require vertical development. One reason for this is that the task of navigating life in a new culture cannot be performed by just relying on conventional patterns of behavior learned in the originating culture, but requires an active process of making judgments about how to navigate in the tensions between different cultural norm systems. Another reason may be that the host society has "higher" mental demands than the society the immigrant grew up in, e.g. expects late conventional or even postconventional meaning-making in various domains (such as in worklife or parenting).[4] Our many conversations with leaders of programs working with immigrants in Sweden indicate that the following challenges are relatively common:[5]

- Your learned way of raising your children may not work in the new situation, because your children experience different attitudes and norms when going to preschool and school in the new country and you are not allowed to use corporal punishment with your children.

- Individuals have far-reaching rights in Western democracies, such as the right to make their own choices about education, work, partner and lifestyle. When children, youth, women and men (e.g. homosexual men) want to take advantage of these rights, serious conflicts can arise within families, clans and ethnic and religious communities.

---

[3] The critical objections concern to what extent Western ego development frameworks are universally valid across different cultures and whether people can be said to be at a particular *general* developmental stage, or if levels of development are dependent on varying situational factors, such as domain, task and degrees of scaffolding.

[4] Again, see the objections to this line of reasoning outlined in Appendix 1.

[5] We have not tried to collect quantitative data on how common these challenges are. Obviously the range of variation is very wide and many immigrants are not significantly affected by the difficulties listed here.

- Your family structure might be seriously challenged, partly because the children learn the language and practices of the new society more quickly than their parents and therefore often have to guide their parents in contacts with institutions, and partly because women learn that they have rights and could get societal support if they get a divorce.

- You will have to interact with people who do not believe in God or who have a different religion from your own, which might be very challenging if you have a conformist mindset.

- You encounter a culture with different norms and values around gender roles and sexuality. The society you live in provides less collective social control, which means that youth get more opportunities to experiment with alcohol, substances and sex, and might more easily get involved in a criminal lifestyle.

- You may not have access to the social support that in your home society was provided by your extended family/clan and may therefore become dependent on social services and other societal institutions.

- It might be necessary for women to get training and get a paid job, in order to earn enough income to support the family, in a context where there are no cultural precedents for women working outside of the household.

- In worklife in an individualistic society with a small power distance, you are expected to use your own judgment, speak up for yourselves and take responsibility for problem-solving to a far larger extent than in a collectivist society with a large power distance.[6]

The larger the gap between the society the immigrant grew up in and the host society is, in terms of culture and socio-economic institutions and practices, the greater the likelihood that the immigrant will be facing some or all of these challenges. It may not be possible to successfully establish oneself in the new environment without a considerable ability to make independent judgments and develop new action strategies. This requires awareness, insight, reflection and active grappling with one's path forward in life. The "mental demands" of being an immigrant to a different type of society are high.

Research Questions

As described in more detail in the section on study design below, this article is based on case studies of six programs that in somewhat different ways use dialogue-based approaches to scaffold self-directed integration of people with immigrant background in Sweden. The aim of the study was to elucidate six interwoven research questions:

---

[6] Individualistic/collectivist and small vs. large power distance refer to the conceptualizations in Hofstede, Hofstede & Minkov (2010).

- What specific challenges do program leaders encounter when using dialogue groups as a path to bridge gaps between immigrants and the Swedish majority society and empower participants to self-directed integration?
- What practices do program leaders use in order to scaffold transformative development for the participants?
- What theories of changes, i.e. beliefs about mechanisms for scaffolding desirable change, underlie the approaches used in the programs?
- Is there a common core of theories of change and practices among programs using dialogue as a strategy to support immigrants in the tasks involved in integrating themselves in the Swedish society?
- Are there significant differences in practices that can be explained by differences in the program conditions, such as differences in target groups, organizational forms or properties of the surrounding community?
- Are there significant differences in practices that can be explained by differences in the meaning-making systems of the program leaders, such as problem framing and theories of change?

In the following section several of the terms used above will be discussed further: scaffolding, empowerment, theories of change and practices.

Elements of a Conceptual Framework

Scaffolding

Recognizing that a society might require citizens to live up to certain expectations in terms of competencies and adherence to norms for behaviors, leads to the question of how the development of those norms and competencies is supported. In discourses about learning and skill development, *scaffolding* is a key concept (Wood et al., 1976). The term scaffolding refers to different types of support offered to an individual (or a collective) enabling the individual to develop and master new skills.[7] There are many different forms of scaffolding, such as showing someone how to perform a particular task, giving constructive feedback, facilitated dialogue, written instructions, checklists to follow and facilitated group processes (Jordan, 2014).

Societies offer a lot of scaffolding for most (but not all) of its native children, youth and adults to develop the skills and forms of awareness necessary for becoming reasonably competent citizens. However, there is a not much scaffolding available for immigrants coming from a very different socio-economic and cultural background. The six Swedish programs studied in our research aim at facilitating self-directed integration, using dialogue as a core practice for scaffolding the development of insights, understanding and skills needed for navigating the Swedish society in successful ways.

---

[7] For critical discussions of the concept, see e.g. Stone, 1993 and Mascolo, 2005.

Empowerment

While all of the six programs we included in our study were designed to contribute to transformation of meaning-making and development of competencies needed for self-directed integration of participants with an immigrant background, there are some significant differences in framings. In particular, there is a certain tension relating to the extent to which program leaders want to influence participants in a specific, according to the program leaders, desirable direction. Two of the programs we included (see below) started based on the ambition to prevent honor-related violence. It is clear in these programs that the program leaders want to influence participants to reevaluate what they perceive as problematic norms, attitudes, beliefs and behaviors (if at all present) and identify with forms of meaning-making based on recognition of each individual's right to make his or her own decisions about how to live life. Other programs are more strongly influenced by the idea of scaffolding empowerment on the participants' own terms, i.e. supporting people to build more action competence to establish satisfying life paths for themselves and their families according to their own needs and wishes.

There is a large and differentiated literature on the concept of empowerment (for overviews and critical examination, see e.g. Adams, 2008; Herriger 2014; Cruikshank, 1999; Pease, 2002). Paths to empowering individuals and collectives can be sought in individual development, shifts in social constructions of identities and values, transfer of resources and transformation of societal structures (e.g. discriminatory practices, educational system, barriers to employment, etc.). In this article, the most relevant form of empowerment is related to transformation of meaning-making and individual competencies.[8] While there is a comprehensive literature on empowerment in the field of social work, relatively little has been written about the very concrete practices that might be effective in scaffolding empowerment (outside of psychotherapeutic settings).[9] In the following section, adult development theory will be used to compile a more differentiated understanding of empowerment as related to individual development.

Dimensions of Adult Development Relevant to Scaffolding Empowerment of Immigrants

Table 1 below gives some details about what kinds of developmental change might be involved in empowerment processes. Most of the elements listed involve vertical transformation, but a few could be construed as horizontal learning. The list was compiled by the author through reviewing the patterns and challenges reported by the program leaders in our case studies and through selecting seemingly relevant aspects of development as conceptualized in key theoretical frameworks in the adult development field. Most of the theoretical frameworks describing adult development take the form of stage models, such as stages of ego development (Loevinger, 1976; Cook-Greuter, 1999; 2013; Torbert, 2004; Kegan, 1994), levels of hierarchical complexity (Commons, 2008; Fischer, 1980; Dawson, 2004), stages of interpersonal understanding (Selman, 1980) and stages in the development of reflective judgment (King & Kitchener, 1994). However, to the extent that stage models represent how adult development actually unfolds[10], they are only in a limited way useful in representing the rather gradual and piecemeal shifts and insights that might be expected to occur in the kind of programs we have been studying. I do not expect programs like these, even if they are very effective, to lead to comprehensive developmental transitions such as those described between stages of ego development. Still, I believe that the developmental shifts described in different stage frameworks are highly relevant for understanding the direction of small developmental changes that contribute to empowerment and desirable transformations of meaning-making patterns.

---

[8] Readers familiar with Ken Wilber's quadrant framework (see e.g. Wilber, 1995) might think of this as focusing the upper left quadrant, while a more comprehensive approach to empowerment would also consider conditions and processes in the other three quadrants.

[9] See, however, the literature on MI, motivational interviewing, which offers a comprehensive set of practices relevant to scaffolding empowerment of individuals (Miller & Rollnick, 2012; Hohman, 2015). However, MI as an approach evolved in a social work setting, presupposing a counsellor–client relationship where there is a recognized problem that clients need to manage. A core concern in MI is how to support the clients to become motivated to find ways to resolve certain problems, such as substance abuse, obesity or abusive behavior.

The programs we have studied do not overtly frame their efforts in terms of scaffolding developmental transformation as described in adult development theory, even though their motivation is to contribute to more insights, more self-confidence, development of life skills and, in some cases, identification with values and norms respecting individual rights and democratic principles. It is more common among programs like those we studied to frame the approach in terms of "empowerment", and of course there is a considerable overlap between frameworks centered on the empowerment concept and adult development frameworks. One argument in this article is, in fact, that adult development theory can offer a far more differentiated and penetrating understanding of what empowerment actually entails, than can be found in the academic literature about empowerment in the field of social work (see e.g. Adams, 2008; Herriger, 2014).

Table 1. Dimensions of developmental transformation

If a person ...	... then developmental transformation means ...	Theoretical references
... has a weak sense of self-esteem ...	... a strengthened conviction of being worth to be taken seriously by others.	Transition from Silence/ Received knowledge towards Subjective/ Procedural knowledge (Belenky et al., 1997). Transition from Socialized towards Self-authoring mind (Kegan, 1994).
... feels powerless and dejected ...	... a strengthened sense of hope, belief in own capacity for action and more clarity about own goals for the future.	Transition from Silence/ Received knowledge towards Subjective/ Procedural knowledge (Belenky et al., 1997). Transition from Socialized towards Self-authoring mind (Kegan, 1994).

---

[10] See Appendix 1.

... is subject to conventional expectations and norms ...	... less dependence on the opinions, beliefs and expectations of others, and development of a self-authored set of values and convictions that enables the person to make independent evaluations of what he or she values.	Transition from Socialized towards Self-authoring mind (Kegan, 1994). Transition from early conventional towards late conventional or post-conventional meaning-making (Loevinger, 1976; Cook-Greuter, 2013). Transition from Silence/ Received knowledge towards Subjective/ Procedural knowledge (Belenky et al., 1997).
... lacks a language for articulating feelings ...	... increased clarity about own feelings and ability to communicate them to others.	Transition from Silence towards Subjective knowledge (Belenky et al., 1997). Increased self-awareness (Jordan, 2001).
... has a weak ability to take own reactions, thoughts, action impulses and interpretations as objects of reflection ...	... increased ability and propensity to become aware of, reflect upon and regulate own internal processes.	Increased self-awareness (Jordan, 2001).
... has categorical, rigid and intolerant opinions, beliefs and attitudes towards outgroups ...	... development of and identification with prosocial norms, such as tolerance, respect, nonviolence and empathy.	Transition from conformist/socio-centric towards conscientious/ worldcentric meaning-making (Loevinger, 1976; Cook-Greuter, 2013; Wilber, 1995)
... has a weak propensity to notice and reflect on psychological and relational causality ...	... increased propensity to notice and reflect on psychological and relational causality and thereby increased ability to play a constructive role in different kinds of social relationships, e.g. in parenting.	Transition from Concrete and Abstract towards Formal and Systematical levels of hierarchical complexity in the domain of psychological and relational reasoning (Commons, 2008).
... lacks reflective awareness of the norms, values and social conventions in the host country ...	... increased reflective awareness of social conventions and an increased ability to manage different types of encounters in the host society: contact with authorities, teachers, colleagues, neighbors, etc.	Transition from pre-reflective towards reflective thinking (King & Kitchener, 1994). Transition from Silence/ Received knowledge towards Subjective/ Procedural knowledge (Belenky et al., 1997).
... is strongly and exclusively identified with a particular system	... greater tolerance in encounters with people who follow other norms, beliefs and lifestyles than	Transition from conformist/ sociocentric towards conscientious/ worldcentric meaning-making

of beliefs, norms and attitudes, and therefore negatively disposed towards outgroups ...	his or her own, as well as greater openness to reflect on different meaning-making systems.	(Loevinger, 1976; Cook-Greuter, 2013; Wilber, 1995)
... limited communication skills, such as open-ended listening and respectful forms of advocating own views ...	... increased skills in listening actively and with respect for others' views, and in expressing own views and convictions constructively and respectfully.	Strengthened skills in listening and advocating (Selman, 1981).
... weak propensity to notice and try to understand how other people feel and think, and understand their needs and desires ...	... increased capacity for role-taking and increased propensity to develop insight into other people's reactions and needs.	Increased capacity for interpersonal understanding (Selman, 1980).

Program Theory and Theories of Change

In order to lay bare the underlying logic of the programs included in the study, concepts from program theory (Blamey & MacKenzie, 2007; Funnell & Rogers, 2011; Pawson & Tilley, 1997) have been used as analytical tools. Program theory evolved within the field of evaluation studies, in order to enable more stringent evaluations of initiatives, often projects, created in order to solve some social problem, improve conditions or realize visions. Key analytical elements in program theory are the notions of *theories of change* and *theories of action*. Theories of change are the conceptions, sometimes poorly articulated, actors have about the causal mechanisms that might be activated in order to achieve a desirable change. Theories of action are the conceptions about what specific and concrete activities might be used in order to allow the change mechanisms to get to work. Program theory also include consideration of problem framing and goals.

Since program leaders often do not have an explicit, considered and detailed discourse about their theories of change, a study such as ours sometimes has to reconstruct underlying theories of change by focusing on what program workers actually do and through probing questions and logical inference work backward to understand and articulate the theories of change that apparently guided their program.[11]

In our study, the main purpose was to make an inventory of theories of change and concrete practices in six Swedish programs that all used dialogue as a means for facilitating integration of immigrants. Next section describes the design of the study, the empirical data collected and the analytical procedure followed.

---

[11] Argyris & Schön (1974) used the distinction between "espoused theories" and "theories-in-use" to point to the possibility that people might say and believe that they operate according to certain principles, but their actual practice might not reflect those principles, but may follow a different logic. It is therefore advisable to focus on what program workers actually do. However, we have not been in a position to conduct participatory observation to any significant extent. The interviews, however, focused on inviting program leaders to describe their actions, rather than their philosophies.

Study Design and Implementation

This article reports on results from a research study carried out in 2017-2019 by three researchers, Thomas Jordan (project leader and author of this article), Pia Andersson and Björn Andersson, all three researchers at Gothenburg university, Sweden. The purpose of the project was to develop knowledge about the theories of change that explicitly or implicitly form the basis of programs that use a dialogue-based approach in order to bridge gaps in views and norms, support relevant knowledge acquisition and support empowerment of immigrants who are still living on the margin of the Swedish society. The study was based on the premise that experienced program leaders probably have developed a considerable amount of know-how about how to make it possible to create a group environment where dialogue, reflection and empowerment can happen. A broader question is how experienced facilitators concretely go about scaffolding developmental transformation when working with this particular group, immigrants from traditional societies. As mentioned in the introduction, the study was limited to making an inventory of theories of change and practices in the programs, leaving analyses of whether these practices actually produced desired outcomes for later studies.

The study comprised detailed case studies of six programs, focusing on the program leaders' narratives, goals, practices and theories of change. In the initial phase of the study, we formulated criteria for selecting programs to study. We wanted the programs to:

- have aims relating to facilitating empowerment and/or integration of immigrants;
- be intending to support transformative change of the meaning-making systems of participants in order to bridge intercultural gaps, and/or reduce problematic differences in norms and/or strengthen the participants' competences in actively integrating themselves in the Swedish society;
- have operated for at least two years and on a scale that warrants the expectation that there is a considerable amount of practical experience and build-up of know-how;
- be led by persons who have been driving forces in developing and leading the programs and who are willing to take part in rather comprehensive interviews.

We also wanted a certain variety of types of principals and target groups. The experience in looking for eligible programs was that rather few programs fulfilled our criteria. Quite a few programs existed only in project form and were discontinued when the project funds ran out. The six programs we finally studied were:

- **Källan**, an interreligious open house center, including conversation groups, situated in Fisksätra, a suburb to Stockholm with a large share of immigrant inhabitants.

- **Att vara förälder i Sverige** [Being a parent in Sweden], a parent support program for immigrant parents, in the city council district Hässelby-Vällingby in Stockholm.

- **Elektra** Gothenburg, offering a leadership development program for suburban youth.

- **Mixgården**, a youth centre in the Gothenburg suburb Hammarkullen.

- **Bygga Broar** in Hörby, a municipality in the south of Sweden. Bygga Broar in Hörby is a branch of a project that aims at preventing honor-related threats and violence, but in Hörby it has been made an integral part of Swedish language courses for immigrants.

- **ENIG** [Establishment program for newly arrived in groups], a program used in several municipalities in the south of Sweden on contract with the Swedish Public Employment Service. The participants were immigrants who have had particular difficulties to enter the labor market and/or learn Swedish through the regular Swedish courses for immigrants.[12]

For each of the programs, we collected available documentation, such as grant applications, reports, plans of operation and manuals and sifted through them for information about the narratives, goals, theories of change and activities. The main basis for the study, however, was the interviews we made with program leaders. We interviewed the program leaders comprehensively about the background of the program, their problem formulation, goals, assumptions, activities, practices and theories of change. The interviews were transcribed and analysed, leading to the construction of comprehensive tables of the program theories of the six cases. The tables have for columns: *Narrative* (problem formulation, assumptions and values), *Theories of change, Practices* and *Goals*. The tables comprised between 2 and 6 pages for each program. The process of identifying and summarizing key elements of the narratives, practices and goals was rather straightforward. The underlying theories of change, however, were only sometimes explicitly formulated by the respondents, and had to be inferred by the researcher. We presented the program theory tables to the program leaders and asked them to comment on formulations that ought to be revised or complemented. This meant that the researcher's interpretations of theories of change were reviewed and confirmed as valid by the program leaders. A further step was to make an inventory of different types of practices mentioned in the interviews and written documentation. A list of 72 practices was compiled (see appendix 2). This list was then presented to the program leaders and they were asked to rate to what extent each practice played a role in their program. This allowed us to gain an overview of which practices were common to all or most of the programs, and which practices were dependent on program-specific conditions or (in a few cases) on differences in theories of change. I also used the program theory tables to identify which practices contributed to which of the three general tasks of establishing relationships and trust, creating an open dialogue climate and scaffolding developmental transformation.

---

[12] After the conclusion of the data collection phase of our study, the two last programs listed have been discontinued for reasons unrelated to their effectiveness.

Tasks and Challenges Facing Program Leaders Working with Integration

Based on the interviews and conversations, as well as document analysis, it seems reasonable to conclude that program leaders who want to create favourable conditions for developmental transformations have three major tasks to handle. The *first* task is to establish contact and relationships between leaders and the participants, so that participants have enough trust in the leaders to be prepared to engage and open up in the group process. The *second* task is to create an open and mutually respectful dialogue climate in the group, so participants feel they can express themselves freely, without risking being put down or attacked when they voice what they really feel and think. These two tasks must be minimally achieved before the *third* and main task can be engaged in earnest: scaffolding developmental transformation among the participants.

It was obvious from the case studies that none of these three tasks is trivial. On the contrary, it may require considerable efforts and skills in order to accomplish the tasks in this particular setting. I have, again based on our case studies, made an inventory of the challenges program leaders may encounter (see the overview in Table 2). Groups and individuals are, of course, very different. In some cases groups present a large number of the challenges listed in Table 2, in other cases conditions are favourable, and the tasks are relatively easily accomplished. In the main section of this article, detailing the different practices found in the analysis or the program theories, the strategies used by program leaders to manage the challenges described here will be discussed.

Table 2. Potential challenges when addressing three tasks

	Trustful relationships	Open dialogue climate	Developmental transformations
Challenges program leaders might face	– Distrust towards representatives of the majority society – Fear of social services – Frustration and anger – Negative preconceptions of the host society – Lack of knowledge about how the host society functions – Defensive attitude due to low-status position – Recourse to traditional norms and identities due to marginalized status	– Expectation of hierarchical leadership – Group dynamics affected by collectivist norms – Status hierarchies between different immigrant groups – Intolerant attitudes and behaviors toward others' belief and value systems – Strong affect in encounters with views that differ significantly from own beliefs, values and norms	– Traumatization leading to reduced openness due to strong affects and defense mechanisms – Lack of language for articulating own feelings and reactions – Lack of experience in reflecting on psychological and relational causality – Lack of experience of being expected to form and express individual views – Low self-esteem and shame – Strong and rigid norms, attitudes and reactions, e.g. in relation to gender norms, sexuality and parenting

Foundational Theories of Change

I reconstructed a large number, more than 60, of theories of change from the narratives of the program leaders. Some of these are very general and foundational for the approaches developed in the programs, while others are quite delimited to achieving very specific outcomes (e.g. increased ability for parents to really listen to their childrens' experiences). I have selected the eight theories of change that seemed to be both foundational and also shared by all the six programs we analysed (se Table 3). In later sections further significant theories of change found in the six programs will be presented.

Table 3. Eight theories of change

Relationships	Building relationships with trust and respect makes openness and developmental transformation possible.
Acceptance	Relating to people with positive interest and a non-judgmental and accepting attitude is crucial for building trustful relationships, an open dialogue climate and for enabling developmental transformation.
Practical activities	Doing practical activities together, both rather unstructured as well as more organized activities, facilitates contact, communication and the building of relationships.
Rules	Establishing guidelines and rules for group conversations and interventions to stop dominating, disparaging and aggressive behaviour among participants, facilitates the emergence of a group climate of mutual tolerance, respect and openness.
Personal stories	Sharing and listening to personal stories invites reflection, e.g. about alternative possible views and courses of action.
Questions	Skillful use of questions can lead to contact, increased trust, reflection, insight into psychological and social causality and development of more mature values, norms and behaviours.
Non-judgmental response	If adversarial opinions and conflicts are received and responded to in a non-judgmental and inquiring way, they can be fruitful starting-points for reflection and developmental transformation.
Knowledge about host society culture	Transfer of knowledge and understanding of how the "new" society functions, both regarding institutions and culture, empowers immigrants to develop action competence.

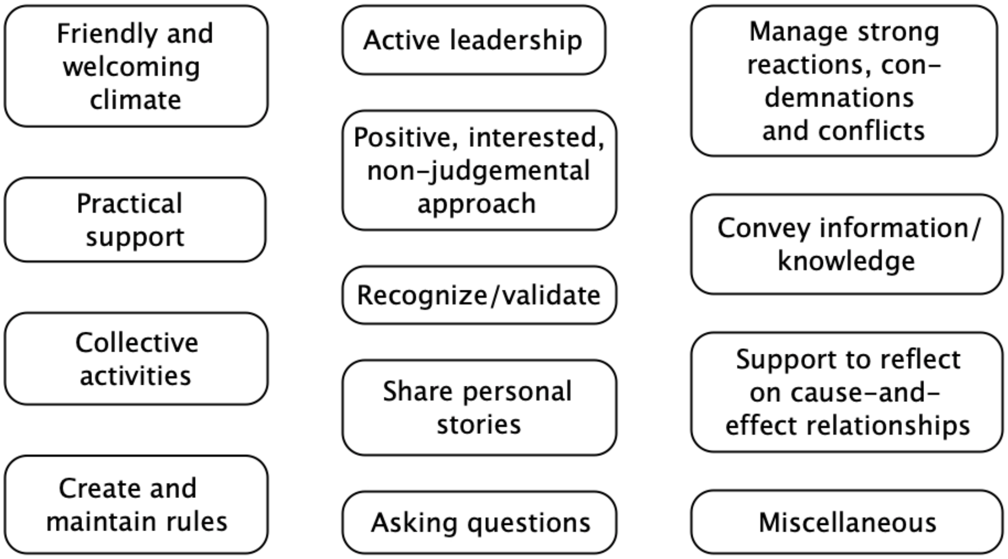
Articulating theories of change in this way is a first necessary step in a process of developing more well-grounded knowledge about effective ways of scaffolding developmental transformation under different conditions (in this case relating to immigrants with significant elements of early conventional forms of meaning-making). Having articulations of the core theories of change makes possible a critical analysis of their credibility, and eventually empirical testing of the extent to which they are actually effective.

Practices

Overview

In the literature on program theory (see e.g. Funnell & Rogers, 2011), attention is focused on what kinds of activities a program comprises. In this study, I found that a more fine-grained approach is needed, as the active ingredients in the programs are less well captured by describing certain types of activities, but are rather found in the ongoing practices of the program leaders. Practices refer here to recurring attitudes and behaviors program leaders believe to be helpful in their work, particularly in group dialogue situations. I believe that a concrete description of such practices is a valuable source of insight into productive ways of scaffolding developmental transformation of such competencies and forms of meaning-making that are necessary in order to handle the mental demands facing immigrants from traditional societies in a modern/postmodern society.

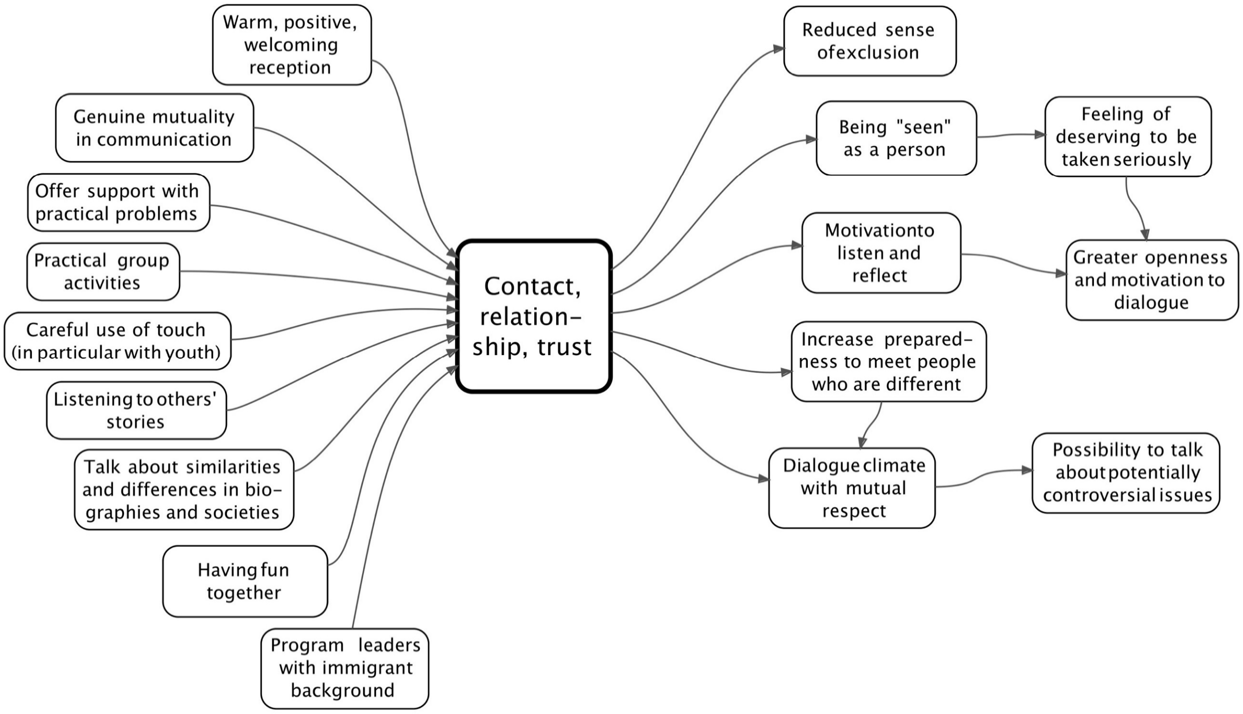
The analysis lead to the identification of 72 practices (some of them overlapping somewhat) that program leaders described as contributing to accomplishing the three tasks of creating trustful relationships, establishing an open dialogue climate and scaffolding developmental transformations. The 72 practices are listed in appendix 2, which also shows to what extent each practice was regarded as important by the program leaders of the six programs. The practices can be subsumed in 12 categories (see Figure 1, with a further "Miscellaneous" category for some practices that were deemed significant but were not as widely used as the others).



Friendly and welcoming climate
Practical support
Collective activities
Create and maintain rules
Active leadership
Positive, interested, non-judgemental approach
Recognize/validate
Share personal stories
Asking questions
Manage strong reactions, con-demnations and conflicts
Convey information/ knowledge
Support to reflect on cause-and-effect relationships
Miscellaneous

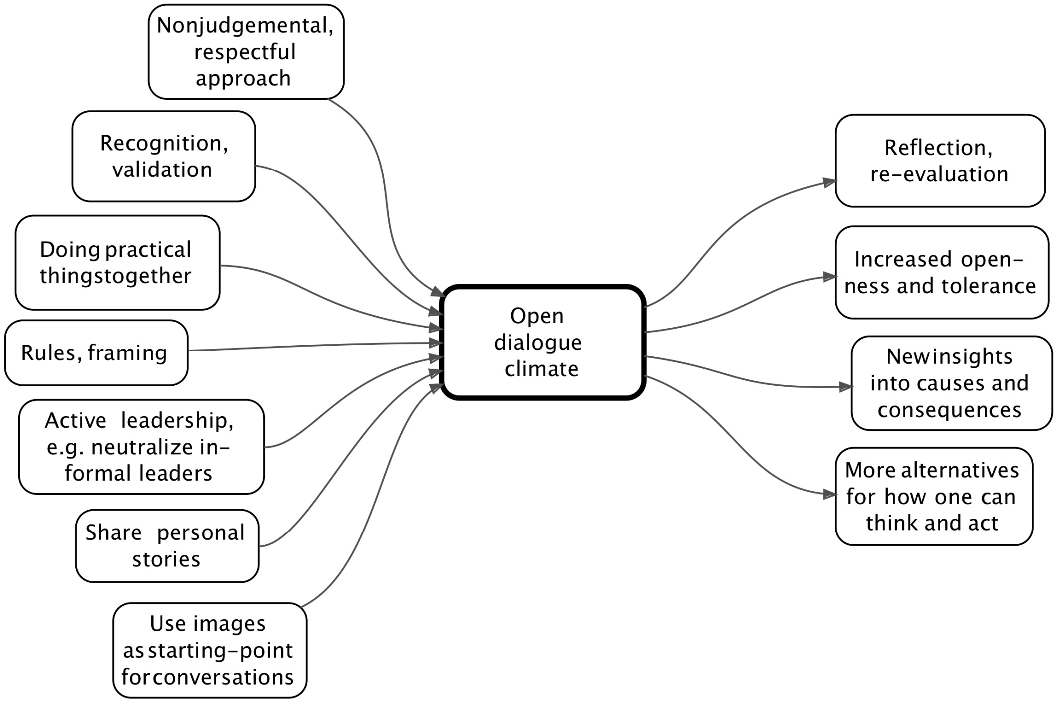
Figure 1. Overview of 12 + 1 categories of practices

Figures 2 - 4 give overviews of the most important practices and how they are explicitly or implicitly thought to contribute to accomplishing the three basic tasks outlined earlier. The underlying theories of change are discussed in later sections.



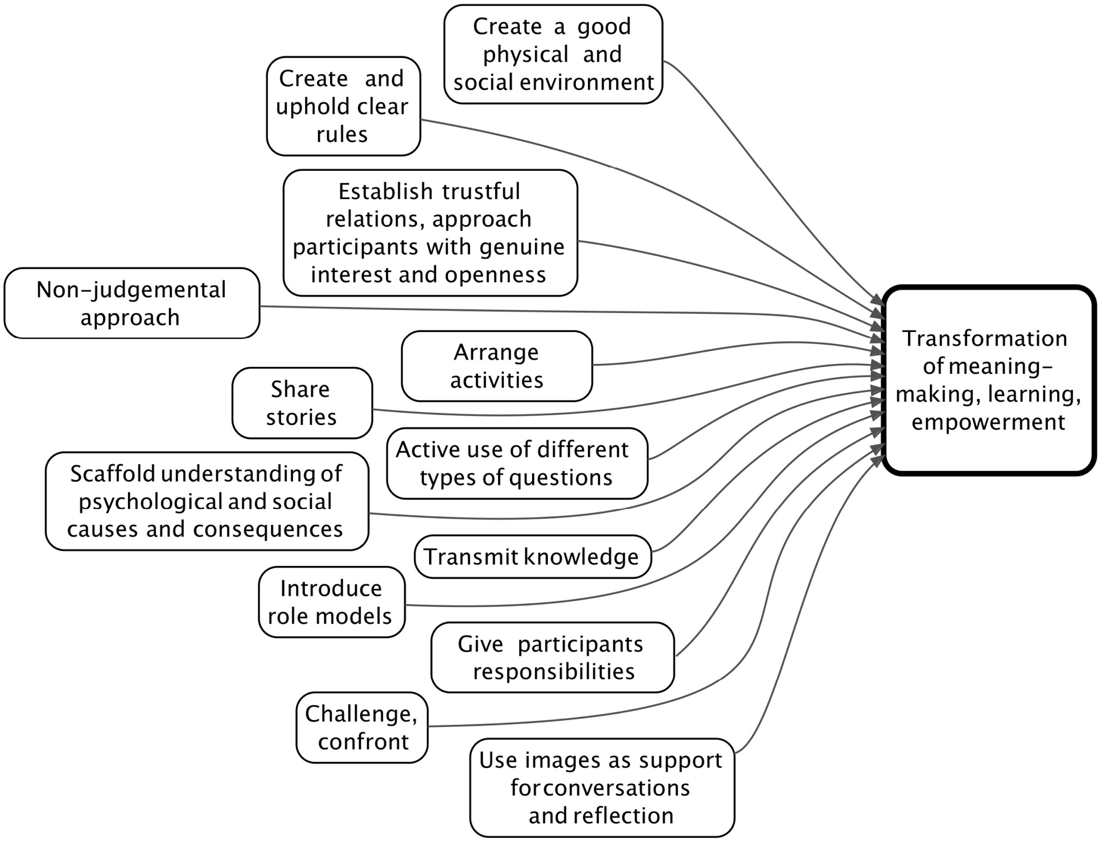
Warm, positive, welcoming reception
Genuine mutuality in communication
Offer support with practical problems
Practical group activities
Careful use of touch (in particular with youth)
Listening to others' stories
Talk about similarities and differences in biographies and societies
Having fun together
Program leaders with immigrant background
Contact, relationship, trust
Reduced sense of exclusion
Being "seen" as a person
Feeling of deserving to be taken seriously
Motivation to listen and reflect
Greater openness and motivation to dialogue
Increase preparedness to meet people who are different
Dialogue climate with mutual respect
Possibility to talk about potentially controversial issues

Figure 2. Practices contributing to establishment of contact, relationship and trust



Nonjudgemental, respectful approach
Recognition, validation
Doing practical things together
Rules, framing
Active leadership, e.g. neutralize informal leaders
Share personal stories
Use images as starting-point for conversations
Open dialogue climate
Reflection, re-evaluation
Increased openness and tolerance
New insights into causes and consequences
More alternatives for how one can think and act

Figure 3. Practices contributing to establishment of an open dialogue climate



Create a good physical and social environment
Create and uphold clear rules
Establish trustful relations, approach participants with genuine interest and openness
Non-judgemental approach
Arrange activities
Share stories
Active use of different types of questions
Scaffold understanding of psychological and social causes and consequences
Transmit knowledge
Introduce role models
Give participants responsibilities
Challenge, confront
Use images as support for conversations and reflection
Transformation of meaning-making, learning, empowerment

Figure 4. Practices contributing to developmental transformation

In the following sections each of the categories of practices are described and their functions in relation to the three main tasks facing program leaders are discussed. Also included in the respective section is a textbox listing theories of change articulated by the program leaders in the interviews we made. The items in the textboxes are not straight quotes, but keep close to the formulations used by the respondents.

1. Friendly and Welcoming Climate

The conditions for hosting are very different depending on whether the program has its own premises and an open-house component or if it is a closed group of recruited participants who meet for a series of meetings, possibly in premises belonging to a different organization. In open-house programs people come for different reasons, sometimes simply to meet other people to socialize with, sometimes because they need help with a specific problem they are facing. For casual visitors to an open-house program, the character of the initial contact with the program leaders is a decisive factor for the likelihood that the visitor gets interested and motivated in participating in a more regular and committed way, e.g. to become a member of a conversation group.

The program leaders working in such programs stressed the importance of greeting each and every visitor in a friendly and welcoming way and show that one is happy to meet the person. Asking open-ended and skillful questions (see the section on questions below) is probably the most important practice for initiating contact and building relationship and trust. The program leader needs to be aware of and sensitive to the fact that visitors may not at all know what to expect from the program leaders, who they are and what role they play (see the section on tasks and challenges above). There may even be a considerable level of mistrust, if the visitor has had negative experiences with representatives of the host society and authorities. All the program leaders agreed that it is very important to have a lot of patience, it may take quite a long time, for very understandable reasons, until visitors or group participants feel ready to open up about their experiences and views.

Again, regarding open-house programs, program leaders stress the importance of quickly learning names of visitors and maybe also learn about their social networks: who they are friends with, family members and other connections. This is particularly important for visitors coming from a collectivistic background, where membership in collectives may be of great importance.

In closed groups, where participants have signed up or been assigned to the group from elsewhere, a friendly and personal hosting is of course also very important in order to build relationship, trust and openness, but the commitment to participate has already been made.

Three of the programs we studied owned or had exclusive use of their premises and were thus free to furnish and decorate the premises according to their own wishes. Program leaders at one of the programs, the youth center Mixgården, strongly stressed the importance of creating a cosy, clean and beautiful environment visitors can feel at home in, identify with and eventually feel proud of. Mixgården also takes care to use symbols in the form of pictures, photos and artifacts from different cultures, in order to create a visibly multicultural environment.

One practice where program leaders had quite different views was the use of physical touch with visitors. Mixgården, the youth center, regard this as a very important practice. They have a massage chair they invite visitors they know well to use. Giving a shoulder massage (with clothes on, of course) creates an opportunity to ask questions about how life is going, build connection and trust that may open up for quite personal conversations. Some of the other programs reported that physical contact is a relatively or very important part of connecting to participants, but then in very mild forms, such as touching an arm or shoulder. But there was also one program leader who avoids any form of physical contact, as it can be inappropriate in some cultures, in particular between men and women. Obviously physical touch can be a powerful means of building rapport, but it has to be used in a very sensitive and prudent way. It is probably far easier for a female program worker to use touch with participants than for a male leader, because of cultural norms about the appropriateness of physical contact between males and females.

Theories of Change

- If visitors are met in a warm, inviting way, they dare to participate.
- If you create an empathic and warm climate, it is easier to establish trustful relationships.
- If there is a welcoming and agreeable hosting, it is easier to establish a constructive and well-functioning social climate.
- If you create cosy and neat premises, a sense of pride and positive self-image is supported among participants.
- If there are visible symbols for different cultures in the premises, the emergence of a multicultural identity is facilitated.
- If you create a social climate that strengthens the sense of belongingness, integration is facilitated.
- If you create a well-functioning social climate the participants are offered a model for how a good social context can function and how one can relate to one another.

2. Practical Support

Some of the program leaders stressed the importance of having been in a position to help visitors/participants in problematic situations, such as handling contacts with authorities, filling out forms and applications, giving advice in difficult family situations or helping people get clothing, dental care or getting other types of basic needs met. The programs we studied have very different circumstances influencing this practice. In the case of Källan, the interreligious center, many of the visitors sought out the center precisely because they had very concrete difficulties: poverty, ignorance of how to deal with authorities or social isolation. At Källan they could talk to people who can give advice, explain letters from authorities, help filling out forms and get warm second-hand clothes for the winter. At Mixgården, the youth center, teenagers can get help with school homework, someone to talk to about family conflicts and other difficulties. In a third program, Bygga Broar, refugees coming to the municipality were received and helped by the same persons who also lead the conversation program that was integrated with the Swedish courses. Also in the other programs, practical assistance was mentioned as a very important factor in establishing contact and building trust, which lowered the thresholds to further engagement.

Theory of Change

- If visitors get concrete help with practical problems, rapport is created and it is easier to build trustful relationships.

3. Collective Activities

Several program leaders regard collective activities, doing practical things together, as an easy and effective way of creating trust, building rapport and creating low tresholds for starting conversations about personally significant issues. In the simplest forms this might be offering coffee or tea without having a specific purpose or agenda. Several of the programs also included more organized activities, such as cooking together, making excursions, having story-telling events or dancing.

One of the good things with arranging collective activities is that doing practical things together without having a more specific goal, such as bridging cultural differences or talking about values, is a very natural and easy way to get to know each other. Conversations start in an unforced way, relationships start to form, trust grows and often people gradually open up and spontaneously start talking about the issues that are important to them. Sometimes this might lead to committing to participate in a more structured program, such as a course or a conversation circle.

For open-house type programs, visitors can come and participate in different activities, which might also offer opportunities to develop social skills. Again, at Mixgården, the youth centre, engaging the youth in working in a music studio or in arranging different kinds of events requires them to take responsibility, collaborate, solve problems and develop discipline and patience.

Theories of Change

- If you do practical things together, you create natural opportunities for people to get to know each other, build relationships and start having conversations.
- If you offer visitors coffee and snacks without a particular agenda, it might be possible to reach people who are not enticed by invitations to participate in a program.
- If you do fun things together, the atmosphere becomes less reserved and more open and relaxed.
- If you arrange activities with low thresholds for participation and if the program leaders are continually available, it becomes easier to get in contact with people and build rapport.
- If participants with different ethnic backgrounds get involved in shared creative activities, xenophobia is counteracted.

4. Creation and Maintaining of Rules

All of the six programs use some set of rules for participation in the program, mostly just a few and rather simple ones. Having a set of rules creates an opportunity to talk about norms for communication and mutual treatment and what behaviors are not acceptable in the context of the program. In the cases where there are structured programs with fixed groups, rules are generally introduced in the introduction to the program. Establishing and upholding rules is, of course, especially called for when working with youth, where adults more or less automatically get the role of conveying norms and enforcing compliance with them. When working with adult participants, there is no mandate to be a moral leader in the same way, but having introduced a couple of rules can be an important form of support in situations where a participants gets upset and acts in an aggressive or disrespectful way. In more serious situations, having an established set of rules can make it easier to temporarily ban a participant (mostly applying to youth) and thereby sending a strong signal about what norms apply.

Theories of Change

- If you have a set of rules it is easier to create a safe and respectful climate.
- If there are clear rules and norms, the participants get a model for how a social community can function.
- If program leaders consistently require compliance with rules it is easier to create a safe and respectful climate.
- If there is clarity about norms, there is support for development of ability to follow social norms, conflict management skills, capacity for adaptation to a social community and ability to take responsibility for shared tasks.

5. Active Leadership

All the programs, in somewhat different ways, include a mandate that the programs leaders are in charge of the group. This role can be used in a number of active ways in order to serve the three tasks described above: create relationships, create an open dialogue climate and scaffold transformation of meaning-making. Being a leader in a group offers the opportunity to lead conversations in ways that ensure that all participants are invited to become active and be open about their experiences and views. The leader may use rounds, where every participant can share what they think, or direct open-ended questions to participants who are shy, reserved or feel unsafe. If the leader notices that there are tendencies for the formation of informal groups that exclude some participants or if there is someone who takes a dominant role or acts in a way that hinders an open and mutually respectful climate, the leader can counteract such patterns by raising the issue with the group, mix up participants in smaller sub-groups for conversations or other activities, or have separate conversations with individuals.

The leadership role is particularly important if someone gets very upset and aggressive, criticize others for their views or in some other way restricts other participants freedom to participate on their own terms. I will return to this issue further below.

Theories of Change

- If the leader actively ensures that everyone can participate actively and be respected, an open climate can develop in the group.
- If a leader intervenes when participants are dominant or disrespectful, an open and mutually respectful climate can emerge.

6. Positively Interested, Non-Judgmental Approach

The program leaders in all six cases we studied stress, in slightly different ways, the fundamental role of meeting the participants with an attitude of genuine interest, acceptance and non-judgment. This is seen as particularly important when the participant is cautious, suspicious, frustrated or preoccupied by other negative feelings, or advocates views that run counter to the program leader's own values. Instead of entering into argumentation, the basic practice is to listen, trying to understand and asking open-ended questions.

There is a striking similarity between the approach voiced by the program leaders and Carl Rogers (1957) conclusions about what enables a positive transformation in psychotherapeutic processes. Rogers' view can be summarized in this way: *If the therapist is congruent (authentic, sincere), shows unconditional positive regard and experiences empathic understanding of the client's internal frame of reference and endeavors to communicate this experience to the client, constructive change will follow.* This is a very clearly articulated theory of change, even if it only maintains that a certain approach works, but doesn't explain the mechanisms by which it works. All the programs leaders we interviewed expressed variants of this theory of change.

Theories of Change

- If you meet participants with a non-judgmental and interested attitude, you can create psychological safety, and the safer you feel, the more you dare to share.
- If there is a genuine mutuality in the communication, trustful relationships can evolve.
- If program leaders can create a sense of safety in the group, developmental processes become possible.
- If an open and non-judgmental conversation climate is created, participants can articulate their questions and prejudices about Swedes and the Swedish society, e.g. regarding parenting and teen sexuality.
- If prejudice and condemnations are met with openness and genuinely inquirying questions, prejudice can be weakened or transformed.
- If one feels that one is free to say anything without self-censorship, it becomes possible to inquire into the background of certain views and formulate and reflect on alternative views.
- If program leaders listen to parents in a respectful way, the likelihood increases that the parents will listen to their own children in a respectful way.

7. Recognition/Validation

Various ways of supporting participants through validation is a common practice in the programs we have studied. The foregoing practice of acceptance and non-judgment in the ways program leaders react, respond and ask questions can be seen as a way to show that one understands and accepts the participant's experience and views. An individual in difficult circumstances might feel incompetent and have low self-esteem. This might evoke defense mechanisms in the form of anger, aggressiveness and a disparaging attitude. Validation in the form of someone else showing understanding for one's feelings, reactions and past actions might normalize the reactions, leading to a greater sense of self-acceptance and a weaker need for upholding defense mechanisms.

Validation can be difficult to practice when a program leader is faced with a participant who states problematic views (see also section below). Validation might here entail showing appreciation for the participant's willingness to be open with opinions and feelings, without agreeing or disagreeing with the content of the statement. One step further is to show one's understanding of the fact that the person has the views he or she has, still without agreeing or disagreeing with the contents. Such an approach might be of great importance in order to create a dialogue climate, where participants feel welcome to be open with their feelings, opinions and thoughts, even regarding issues where there are very diverging views.

A different form of validation, also common in the programs, is to show appreciation and approval of actions participants have taken, for example in their roles as parents. Leaders might also invite other participants to offer positive feedback to each other.

Theories of Change

- If participants get validation from other participants and/or from leaders for good things they do, their social skills are strengthened.
- If participants' actions are validated, a positive self-image and hope for the future can be strengthened.
- If participants' difficulties are normalized, their prospects for handling crises are improved.

8. Sharing of Personal Stories

For programs where groups meet over an extended period of time, the sharing of stories about personal background, experiences and other personal issues is an important activity. The sharing of stories, among participants, but also by leaders, may have several functions. It creates rapport and is a way to initiate conversations about personal experiences and views. The telling of personal stories, and in particular the listening to others' stories, creates relationship, understanding and respect. By listening to others' stories about their experiences, participants have the opportunity to reflect on similarities and differences in relation to their own stories. People deal with and think about situations in different ways, which offers the individual a broader range of alternative ways of interpreting and feeling about significant matters. A particularly important effect can be when someone has an acute challenging situation and by listening to stories of how others dealt with similar situations might get hope and motivation about his or her own challenges.

Several program leaders mention how they, often with some caution and reservations, share stories from their own personal lives with participants. Sometimes leaders share something about how their personal (but not too private) situation is at the moment, in order to set a more personal tone in the conversation. Some leaders also tell participants about their own backgrounds, events they were part of, or experiences that illustrate existential human dilemmas and consequences of different courses of actions. Being more personal creates rapport and contributes to open up the informal norms regarding what is spoken of and how one can talk about personal matters.

It might be difficult for program leaders to know how to act when participants want to know the leader's personal opinions in, for example, political issues, religious beliefs or attitudes to controversial phenomena. Most program leaders have roles in which they feel that they should be restrained in voicing personal opinions regarding contested issues. However, there are situations where it feels appropriate to share personal views, in particular when it might lead to a genuine dialogue about themes that might involve divergent opinions.

Theories of Change

- If participants share personal stories, mutual respect and trustful relationships are likely to develop.
- If participants get the opportunity to hear others' stories, they can reflect on their own experiences, on causal relationships and on alternative courses of action.
- If participants get to hear how other people have dealt with similar difficulties, they might get new insights about how they can navigate their own challenging situations.
- If a program leader shares stories about his or her own biography and own experiences, it is easier to create rapport, trust and openness.

9. Asking Questions

Asking questions is one of the most important tools of a program leader. Different types of questions can be used in order to scaffold the attainment of all the three goals mentioned earlier: establish trustful relationships, create a respectful dialogue climate and transformation of meaning-making in order to empower participants. Simple, ordinary questions are a natural way of making contact and start conversations with people. The way questions are asked can convey that you are benevolent, interested and genuinely open to listen to the other person. This creates rapport and trust and is the start of building a relationship that allows conversations about personal and significant issues, including sensitive and controversial themes.

However, questions are also a powerful means of influencing other people in potentially profound ways. A program leader often asks questions not in order to get certain information, but rather to offer the participant an opportunity to reflect on matters that have not been objects of reflection before, at least not from the particular angle the question invites to. Since questions might influence people to think and feel in new ways, asking questions does mean that there is a power dimension in the relationship: the program leader wants and can influence the participant in certain directions without the participant being fully aware of the intention behind the questions asked.

The analysis of the interviews we made led to the identification of nine categories of questions used by program leaders (see appendix 2).

The two first types are used for initiating contact and conversation and for creating a relaxed and respectful conversation climate. Program leaders use open-ended questions about how different daily life themes are handled in the participants' home countries, such as: What did your family and closer relatives network look like at home? Who took care of your children when they were small? What kind of school did the children attend? How did you support the family? What was it like to be a teenager? Some questions are rather innocuous, while other questions might lead to more sensitive themes requiring more of a safe group space, such as questions about differences in parenting styles or questions about how the participants came to leave their homes and travel to Sweden. A particular way of using the same type of questions is when a program leader notices that one or several participants are very reserved and silent, maybe due to insecurity or lack of practice with talking in front of people they don't know very well. In such cases, a program leader can direct innocuous questions to these participants in order to get them to participate in the conversation, such as what they usually had for breakfast, or what kind of home they lived in.

The other categories of questions found were all used for supporting reflection, clarification and insights. Some types of questions are used at occasions when a participant voices views or emotions that need to be handled in order to maintain an open and respectful dialogue climate, such as when someone makes strongly disparaging comments or is very upset. As already mentioned, in all six programs we studied, program leaders mostly do not start arguing against problematic views, but remain anchored in an attitude of acceptance, curiosity and respect. Exceptions to this basic approach were reported in the two programs working with young participants, where program leaders sometimes feel called upon to challenge participants about problematic speech. Open-ended questions about the participants' personal experiences or other background to opinions and emotional reactions mostly leads to a calming down of the situation and it becomes possible to explore different possibilities for how one can think and feel about different themes. Several of the program leaders reported that they often handle situations when one participant voice problematic views by asking other participants how they think and feel about the issue in order to get a more reflective conversation going.

A particular category of questions are intended to support a person to direct his or her attention towards own emotions, reactions and thoughts, in order to gain more clarity about how one feels, the underlying reasons for one's reactions and not least in order to support the person to find words for describing what is going on in one's interior.

In German literature on conflict management (see e.g. Thomann, 2002), there is a pertinent word for this: *Selbstklärung,* self-clarification. The word points to the process of developing clarity about how one feels and thinks about a particular issue or experience. Assisting the conflict parties to gain clarity about their feelings, needs, values, thoughts, priorities and what outcome they want can be a crucial element in a conflict management process, and is also highly relevant in this context. Some of the questions asked in order to scaffold such self-clarification are rather simple: How do you feel about this? What thoughts do such situations trigger in you? What is most important to you when such things happen? How would you like it to be? Is there something specific you are worried about?

Theories of Change

If a program leader skillfully uses questions, outcomes can be:

- increased rapport and trust;
- that participants feel seen and therefore also welcome to participate actively;
- that conversations get started and participants increasingly open up;
- that participants who are upset calm down, talk in a more open-ended manner, start reflecting and make decisions in a more considered way;
- that participants by articulating their feelings, reactions and views gain more clarity about themselves and what is important to them;
- that participants become more aware of other people's reactions, feelings and views;
- that participants gain new insights into causal connections in interpersonal relationships, such as how different parenting styles affect children;
- that participants start reflecting on taken-for-granted views, beliefs and attitudes, and maybe reevaluate them;
- that participants reflect more concretely and realistically about their own and their families future and what they would like to accomplish.

10. Handling Strong Reactions, Disparaging Attitudes and Conflict

Significant differences in norms, attitudes, beliefs, knowledge and behaviors among participants and between immigrants and the Swedish society are an integral aspect of the programs we have studied, and for some of them the very reason that they exist. These differences can, when they surface, elicit strong reactions and conflict. The encounter with norms and beliefs that are very different from the ones participants have taken for granted and may be strongly identified with can be felt as strongly provoking. In addition, many refugees and other recent immigrants have had frustrating experience with authorities and in other situations in the new society, and may carry along negative and strong emotions and/or have developed a considerable degree of distrust in relation to representatives of the host country. Some participants may also be traumatized by experiences in war-torn regions when fleeing and by loss of relatives or friends. Conversations in a group may activate strong painful emotions, like anxiety, despair and fear for the safety of relatives.

A program leader must be prepared to deal with situations where participants react with painful emotions or tell stories with horrible and traumatic ingredients. However, in situations when participants express hostile and disparaging views towards other participants in the group, towards the Swedish society or towards specific groups, e.g. homosexuals, the leader's skillfulness in upholding an open and respectful dialogue climate is really put to the test. Some views expressed by participants may feel provoking in relation to the leader's own values, e.g. when someone maintains that it is a good thing to use corporal punishment with their children, or condemns certain categories of people. But even if the leader does not have their own reactions to deal with, there is still a need to handle the group dynamics in order to create and maintain an open and respectful climate.

When emotionally charged situations happen, in particular when a participant expresses problematic views, the program leader will have to choose to what extent these statements should be received with a non-judgmental and inquiring attitude, and to what extent it is called for to challenge the views or even stop a participant from hurting other participants.

Theories of Change

- If strong emotional expressions and disparaging attitudes are met with a non-judgmental and inquiring approach, shared reflection and reevaluation may become possible.
- If participants get support to reflect on conflicts, misunderstandings may be reduced, insight into causes and consequences in social relationships may increase and stereotypical conceptions may be dissolved.

11. Inform and Educate

All of the programs regard sharing of information and knowledge in order to make the new host-society intelligible as an important component of their work. Understanding of causes and consequences in relation to contested issues, such as parenting styles, sexuality and differences in norms and lifestyles, is likewise regarded as a central task. Several of the program leaders stress that it is important and helpful to take care to refer to research results and verifiable facts in order to gain credibility and legitimacy, as well as providing a good starting point for reflection and dialogue.

Immigrants need knowledge about Swedish laws, rights, institutions and regulations in order to be able to advocate their interests and handle different situations they may find themselves in. Some recurring topics is to explain the taxation system, the roles and principles of the social service authorities, laws, the judicial system, the compulsory school system, etc. Understanding how these systems work can reduce misunderstandings and strengthen action competences.

There is also often a need for understanding a range of phenomena in the Swedish society that are not part of the societal structure, but rather cultural phenomena, such as pervasive norms, attitudes and behavioral patterns, e.g. regarding parenting, sexuality, gender roles and equality, leadership styles, the weak role of religion and widespread patterns of social interaction that may be very different from what participants are used to.

The programs that aim at preventing honor-related violence and promote respect for individual rights include further forms of knowledge dissemination. Specific themes that are part of some programs are knowledge about children's needs, consequences of different types of parenting, risks related to cousin marriages, facts about the hymen and risks related to circumcision.

Theories of Change

- If the program conveys knowledge about laws, rights, regulations and about how Swedish institutions function, misunderstandings and anxiousness can be reduced, and participants can better advocate for their interests in the Swedish society.
- If leaders share knowledge relating to potentially controversial themes, such as parenting, the hymen and family violence, it becomes easier involve participants in reflection and possibly also reevaluation of problematic attitudes, norms and beliefs.
- If participants get support in understanding psychological causality (e.g. the mechanisms of shame), the amygdala can be calmed down, the frontal lobe can be strengthened and it becomes easier to mobilize hope and motivation to develop new behaviors.
- If participants gain greater understanding of the challenges one faces when one migrates from a traditional society to a secular and modern society, reorientation is facilitated.

12. Support for Reflection on Causal Links

A large share of the participants in the studied programs grew up in social environments that lacked scaffolding for reflection on psychological and social causality. Several of the programs use activities that actively invite to such reflection. One example, used in Elektra and Bygga Broar, is to ask participants to draw "life lines", a line symbolizing high and low points in the biography with marks for specific life events. The line can be used for reflecting on how different events and circumstances in one's biography has contributed to forming one's personality and attitudes. Another example is when program leaders talk about how family structures may be impacted by migration, differences in living in a society in war and a society in peace, and how the difficulties facing immigrants in a society that is very different can lead to shame and avoidance. Here sharing of concepts and theories are combined with invitations to reflect on causal links in the participants' own lives and predicaments.

A further variation is to invite participants to tell each other how it feels and what other consequences follow in particular situations. One example is how leaders at Elektra have invited girls to tell boys how it feels for them when the boys look at porn. In programs for parents, program leaders may invite participants to imagine how it feels for their children in certain situations and when they are treated in certain ways.

The practice of scaffolding reflection on psychological and social causal links is, of course, a key element in promoting transformation from pre-formal to formal cognition, i.e. from early conventional to late conventional meaning-making.

Theories of Change

- If participants are supported to articulate their feelings and reactions, they feel seen and validated and it gets easier to reflect on own experiences and their consequences.
- If parents are invited to reflect on their children's situation and experiences, the likelihood increases of functional parenting adapted to the situation of being an immigrant in the Swedish society.

Miscellaneous Themes

In addition to the themes discussed above, there were seven practices that were deemed potentially significant, but were only mentioned in some programs. Some of them are only relevant under specific conditions, such as in programs targeting youth.

Images. All six programs reported that they use images for supporting conversations and knowledge transmission, but there were significant differences in how this was done. In Bygga Broar the use of images is central to the whole program. In Bygga Broar a lot of time and effort has been invested in developing a series of 40+ drawings intended to facilitate starting conversation with immigrant parents about a broad range of themes, mostly relating to the situation of their children. Many of the drawings show children in different situations, inviting conversations about children's feelings, parenting, gender roles, family violence, circumcision, etc. The experience in the program Bygga Broar is that the images make it much easier to initiate constructive conversations about potentially charged issues. The other programs often use images as a support when talking about various themes, but not in the systematic way characteristic of Bygga Broar.

Individual feedback. Offering individual feedback to participants is a practice that played a role in only a few of the programs, in particular Elektra. Since Elektra essentially is a leadership development program for suburban youth, leaders have a natural mandate to take initiative to have an individual conversation with a participant and offering observations and suggestions regarding behavior in different situations and sharing own experiences and learning about leadership. In other types of programs, the mandate for giving individual feedback is weaker, but may be called for in specific situations.

Training skills. Participation in a group led by someone who is skillful in creating an open and respectful dialogue climate implies in itself training in listening and talking skills, in particular for participants who have little experience with such forms of communication. However, there were not many examples in our case programs of activities that were specifically intended to train particular skills. In the ENIG program, one session is devoted to understand and train validation, i.e. giving and receiving positive feedback, including a homework assignment for training with family members and other people. The program that could be said to offer most opportunities for development of social skills is Mixgården, the youth center. Mixgården offers a range of activities, including, as mentioned above, giving participants responsibility for certain tasks, but also participating in activities that require sustained learning and training, such as dance, recording music or planning and carrying out various types of events. Such activities offer opportunities to develop social skills, such as collaboration, problem-solving, taking responsibility, develop more patience and work discipline, planning and tolerating differences.

Responsibility. A couple of the program leaders pointed out the importance of assigning real responsibility to participants for various tasks, as a way of mobilizing engagement, commitment and development of social skills. This is a very significant part of the youth centre Mixgården's approach. Teenagers in different constellations are invited to assume responsibility for roles like operating the café or the music studio. They also have the practice of picking a number of participants each year to form a group that is given a set of responsibilities over the whole year. In the program Bygga Broar (not so much in the part we included in our study, but elsewhere), immigrant women were invited to take on the role of being cultural interpreters and speak in front of groups of Swedish preschool and school teachers. The program leaders reported that this element of the program had a large impact in generating engagement and commitment, as well as increasing self-esteem and a sense of personal agency. Using the practice of assigning responsibility for real tasks and roles is much easier in programs having a variety of activities going on. It is less easy in programs comprising a series of conversation meetings. However, even in such groups the practice of assigning responsibility can be used to some extent, for example by giving participants homework assignments and ask them to report back on these.

Role models. Some of the programs, in particular Mixgården and Elektra which work with youth, regard working with role models as an important practice. They may, for example, invite guests, such as former participants who have managed to establish themselves in a particular role in the wider society. By meeting people like themselves who have succeeded at getting a meaningful job or becoming an artist, for example, participants get living proof of the possibilities that exist for themselves and their own future.

Referring to religious norms. In two of the programs leaders sometimes referred to religious norms in relation to participants for whom religion has a personal significance. In the cases this was mentioned as a practice, the leaders themselves had a background in Muslim societies and were familiar with the Koran and could therefore with some credibility use relevant quotes. For example, a program leader could say "Only God can judge" when a participant expressed him- or herself in a disparaging way about other people. However, some program leaders also expressed a certain ambivalence about using religious authority as a strategy.

Working with oneself. Practices explicitly emphasising the need for program leaders to work on themselves were not often mentioned in our interviews. Some program leaders, however, did refer to the importance of working on being aware of one's own state of mind and actively taking care of, for example, strong emotions or particular moods, as well as continuously training on being able to maintain an empathic attitude towards participants.

Similarities and Differences Among the Six Programs

Of the 72 practices identified in this study, a large share, about 32, were reported as very important by all or most of the six programs (see details in appendix 2). This means that there seems to be a rather large set of practices that are common to practitioners in this field, even though they have built their programs independently and don't have a background in a particular methodology.[13] However, there were about 40 practices not used by all programs in a regular way. The reasons for this were different. For about 14 of the practices, it was apparent that their relevance was dependent on specific program conditions. Some practices are only relevant for programs owning or having exclusive use of their premises. Other practices are only relevant or important when working with youth. A third type of differences in conditions are between open-house programs and programs in the form of a series of group meetings with a more or less structured agenda. In the former case, different types of activities can be offered, in the latter case teaching about different topics is a common ingredient in the programs.

Surprisingly few differences in what practices are used (about 16) can be related to differences in theories of change, i.e. beliefs about what is helpful. None of these represent strongly diverging philosophies. The most significant differences concern to what extent program leaders should try to influence participants in particular directions, such as challenging views perceived as problematic or actively inviting participants to reflect on certain issues. Most differences, however, can be interpreted as differences in emphasis, i.e. what is regarded as more or less important to do.

The remaining about 10 practices, where there were differences between the programs, did not seem to have particular explanations. The respondents simply could not report that a particular practice had been called for, or they had never considered that it might be useful.

Quite a few of these practices may sound very ordinary, almost trivial, but in the programs we studied it was clear that they were practiced mindfully and methodically, as elements in an cohesive "method" or approach.

Conclusions

In this paper I argue that it is important to provide scaffolding for immigrants faced with the challenge of acquiring knowledge, skills and meaning-making patterns necessary for self-directed integration in individualistic societies expecting citizens to be self-authoring. Failing to provide such scaffolding increases the risks of growing marginalized groups, forming enclaves with much worse living conditions than the majority population. This might lead to increasing tensions in the society and increased appeal for young immigrants to join criminal networks, thus not only affecting the immigrants themselves, but also to the stability and dignity of the society at large.

---

[13] We asked the respondents if they had participated in courses in any particular methodology. Some of them are familiar with MI, motivational interviewing, and have attended shorter trainings in the methodology. However, it was apparent from the interviews that none of them regarded this as a major and formative influence in their approach, but rather a complementary input.

The study reported here aspires to contribute to our knowledge about how developmental transformation can be scaffolded, with particular reference to immigrants from traditional societies. Leaders of the six programs we studied share the foundational theory of change that building trustful relationships is a crucial precondition for creating an environment conducive to empowerment. Establishing trustful relationships and an open, respectful dialogue climate under these conditions may require more of program workers than in settings were participants have a similar cultural background.

The analysis of the program theories of the six programs included in our study yielded an inventory of 72 practices used by all, most or some of the interviewed program leaders. A large share of these practices were regarded as very important in all or almost all of the six programs we studied. Some practices are only relevant under certain program conditions (such as having own premises, or working with youth). One might have expected that some differences in what practices were used in the different programs would reflect different profiles of the program leaders' theories of change. However, few such differences could be discerned in this study.

The study did not aspire to measure to what extent the identified practices actually contributed to the empowerment of program participants. We therefore cannot assess if the theories of change shared by the program leaders are effective. However, it can be argued that the practices identified constitute a comprehensive set of "promising practices," worth further exploration, and development. They are the result of the accumulation over time of know-how among program leaders with a considerable experience in meeting and working with people with an immigrant background, primarily in group settings. Anecdotal evidence suggests that practices such as a positive and non-judgmental approach, skillful use of different types of questions, sharing personal stories and support to reflect on psychological and social causality can be powerful forms of developmental scaffolding.

The inventory of practices (see appendix 2) can be regarded as a framework that can be used both by researchers in further investigations and by practitioners who want to reflect on and develop their skills and practices. The identification of a comprehensive set of practices and their underlying theories of change is a first step in an investigation into effective ways of scaffolding empowerment of individuals to increased ability to navigate life in society that expects and requires meaning-making and action patterns corresponding to late conventional stages of ego development.

Appendix 1. Theoretical Controversies in the Application of Adult Development Perspectives in Migration and Integration Studies

The writing of this article and the reactions the first version evoked among those who read it (researcher colleagues and reviewers) opened a can of theoretical worms. The contents of the can seem to involve deep-seated differences in perspectives within the adult development field that would deserve to be thoroughly explored. However, the issues involved are too complex to be satisfyingly resolved within the context of this article, which was meant to focus on rather concrete results of a case-based study of scaffolding practices. The feedback I received gave me reason to rewrite the problem framing section of the article to accommodate the critical objections. I am not fully satisfied with the result, though, and I think it is relevant to outline some of the interesting theoretical tensions involved.

My personal problem framing that lead me to design the research project reported in the article were based on assumptions that might be described something like this:

- Adult development theories offer a unique (but partial) interpretative approach to understand and manage important aspects of complex societal problems, such as the integration of refugees and other immigrants from low-income and war-torn countries to high-income, democratic societies.

- Adult development theories describe significant and hierarchically ordered levels of cognitive skills, social awareness, self-awareness and self constructions (e.g. Kegan's subject-object balances).

- Different societies scaffold its members' development up to, but not beyond, a certain expected level. This expected level is different in different societies.

- Some societies actively discourage its members (or some of its members, e.g. girls and women) to develop beyond the wanted level.

- Some societies, or rather social milieus, in the world function according to an early conventional, or conformist, mindset. An early conventional, conformist, society is one where:

    - members are expected to believe in and adhere to a quite narrow and rigid set of norms and beliefs;
    - there is a lack of tolerance towards deviations from these norms;
    - there is a considerable tendency to divide people into Us and Them;
    - narratives about who is good and who is bad are prominent aspects of the worldview;
    - the cognitive world is rather undifferentiated, dominated by black-and-white, either-or thinking; and
    - authority is perceived to be external rather than internal.

Often, but not necessarily, the social order of the society, organizations and families is hierarchical and patriarchal.

- Immigrants originating in early conventional societies are a very diverse group, but some have not had the chance to develop beyond the early conventional ego stages. When people embedded in an early conventional (conformist) stage of meaning-making migrate to a society that expects its members to function at late conventional levels (for example be self-authoring and having principled, world-centric values about tolerance for diversity), they are faced with challenges they have not been equipped for. These challenges may for some be very difficult to handle and thereby become obstacles to integration.

- If immigrants from conformist social milieus do not adapt to the host society's norms and practices, there is a considerable risk that they will remain outsiders in relation to the majority society, economically (support oneself and one's family), socially (segregated lifestyle) and culturally (rejecting the host society's values and norms, and, possibly, acting out norms that are in breach of the host society's laws and prevalent norms).

- Social exclusion of whole groups of immigrants may lead to several social ills, such as widespread long-term unemployment, dependence on social security benefits, increased propensity for young men to be attracted to criminal networks, suppression of in particular girls' and women's rights (according to the host societies legislation) to make their own choices and ethnic conflict. Some of these phenomena may also reinforce tendencies to xenophobia and ethnic discrimination.

- It is, for these reasons, a crucial task for the receiving societies to provide effective scaffolding for the immigrants, to facilitate their empowerment and enable self-directed and constructive integration.

The problem framing in the first version of the article was not spelled out in the detail given above, but enough of the underlying assumptions were present to evoke objections from colleagues and reviewers. The most fundamental objections are, according to my interpretation, related to differences in convictions about the nature of adult development.

One objection is based on the conviction that it is fundamentally misleading to describe adult development in terms of individuals developing through a sequence of general stages, as the ego development framework do. According to the view behind this objection, development is localized, i.e. domain-specific and highly dependent on situational factors, such as what particular task the individual is engaged with, what scaffolding is provided in the actual situation and the properties of the social setting the individual is embedded in. Individuals are not "at" a certain stage, but operate on different levels of complexity on different occasions. There is research (e.g. by Kurt Fischer, Theo Dawson and their colleagues) that shows that individuals' performance and developmental trajectories in terms of complexity levels are domain-specific. In the light of this view, it is highly misleading to make generalizations about what stage a person is at.

A second objection is related to the concern that the stages and levels frameworks developed in the adult development field reflect what is valued and regarded as mature in North American and Western European societies. The cultures in these societies are strongly individualistic, whereas large parts of the world have collectivist value systems. However, the theoretical frameworks developed in the Western environment, in particular the ego development frameworks, claim to represent universal developmental patterns. This is deeply problematical and risk portraying meaning-making systems based on other cultural values and norms as less developed, thereby also contributing to a deeply misleading "deficit" stereotype of immigrants as a collective. Serious consideration of the variability in forms of social organization, cultural patterns and value systems raises the question if it is at all possible and meaningful to create universally valid theoretical frameworks for adult development.

Two reviewers recommended that I, in the light of these objections, should remove the references to needs for vertical development among (some) immigrants, and frame the challenges involved in terms of a need for horizontal learning about cultural differences. This could still be thought of in terms of developmental transformation, but not in relation to a universally valid hierarchical model of adult development.

Even though I recognize the validity of the objections sketched above, I have been quite reluctant to completely abandon the vertical development angle. I do believe it *is* relevant and meaningful to apply concepts like early and late conventional meaning-making to collectives that to a considerable degree are communities of shared values, norms and assumptions. However, I have only anecdotal rather than systematically documented evidence to go by regarding the presence of early conventional systems of meaning-making among (some of) the participants in the programs we have studied. There is also, as far as I know, no stringent theoretical framework that would allow us to define the properties of early and late conventional and postconventional *societies* and "score" particular societies. The objections concerning the potential incommensurability of different cultures of course also call into question if it is at all defensible to develop and use such frameworks. I believe these issues deserve to be explored in depth and with intellectual rigor. That, however, is a task far beyond the scope of the present article.

Appendix 2. Practices: Compilation of Responses from Six Programs

The table below shows how program leaders rated the use of each of the 72 practices found in the analysis.

Explanation of symbols used:

–	Not used by us
*	Used to some extent
**	Relatively important
***	Very important, central for my/our approach

K: Källan; A: Att vara förälder i Sverige; El: Elektra; M: Mixgården; EN: ENIG; BB: Bygga Broar

Categories	Practices	K	A	El	M	EN	BB
Basic attitude	1. Being anchored in a curious, positively interested and non-judgmental attitude in the lifeworlds of participants. Listening with an open-ended attitude, rather than advocating or teaching.	***	***	***	***	***	***
Friendly and welcoming attitude and environment	2. Having a friendly, welcoming and inviting way of hosting.	***	***	***	***	***	***
	3. Taking care to greet each person, learning everyone's name, learning the social networks of participants.	**	***	***	***	***	***
	4. With sensitivity for boundaries using physical touch: shake hands, touching visitor's arm or shoulder, hugs.	*	***	**	***	_	**
	5. Creating a cosy ambience in the premises.	**	***	**	***	*	***
	6. Creating a multicultural ambience by having symbols of different cultures, and learning and using words from different languages.	**	**	_	***	*	**
	7. Being patient that it may take some time before participants are prepared to be open with their experiences.	***	***	***	***	***	***
Practical support	8. Assist individuals in problematic situations, such as contacts with authorities.	***	***	***	***	_	**

Collective activities	9. Create relaxed and unpretentious opportunities for taling, establish contact and build relationships by offering coffee or tea, eating together, being available for spontaneous contact.	***	***	***	***	*	*
	10. Arranging activities that create opportunities for contact, conversations, creating rapport, such as cooking together, arranging events, making excursions.	**	*	***	***	_	*
	11. Arranging and/or creating conditions for creative activities, such as working with art, making music, dance courses.	***	*	***	**	_	*
	12. Taking care to have fun together, joking with participants.	*	***	**	***	***	***
	13. Organizing solidarity activities, such as collecting money for aid projects.	_	_	*	***	_	_
Create and maintain rules	14. Present rules for participation in the program, such as respect for other participants' views.	***	***	***	***	***	***
	15. Require compliance with rules, making sure that violation of rules have distinct consequences, and following up and reintegrate those who have transgressed rules.	***	**	***	***	_	*
Leading	16. Distribute talking time in order to activate everyone or giving everyone opportunity to speak.	***	***	***	***	***	***
	17. Actively discourage the emergence of informal groupings and informal leaders.	***	***	***	***	*	**
	18. Raise the issue with the group if someone is marginalized.	_	***	**	***	_	***
	19. Taking care to uphold a leadership role - not becoming a friend.	***	***	***	**		*
	20. Intervene when a participant inhibits other participants. Request that participants respects others' views. Refer to rules, negotiate contracts.	***	***	***	***	***	***
Recognize/ Validate	21. Welcome when participants express problematic views by conveying that it is	**	***	***	**	***	***

	good that they are open, rather than entering into polemics.						
	22. Show understanding and acceptance (without agreeing) in relation to participants' attitudes, opinions, feelings and judgments, even when they are problematic (e.g. racist opinions, authoritarian convictions).	_	***	**	**	***	***
	23. Show understanding for the challenges and difficulties facing immigrants to a different type of society.	**	***	***	***	***	***
	24. Offering validation to participants for the constructive and good things they do, and inviting other participants to offer validation.	**	***	**	***	***	***
	25. Conveying that it is OK to be wrong and not knowing everything.	**	***	***	***	***	***
Being personal in the leader role	26. To some extent share personal information, in order to model what can be talked about.	*	***	***	***	***	***
	27. Sharing aspects of own life story and own experiences.	*	***	*	***	**	***
	28. Stating own opinions regarding different issues.	*	*	*	***	*	***
	29. Sharing own experiences of coming to Sweden as a foreigner.	*	***	_	***	**	***
Asking questions	30. Asking open-ended questions about how different issues are handled in the home countries of participants, such as childcare, parenting, freedom and control.	**	***	*	***	***	***
	31. Asking questions, e.g. about the home country, directed to participants who are reserved, in order to activate and include them.	*	*	***	***	***	***
	32. Asking non-judgmental questions that invite to reflection on the background to problematic attitudes (e.g. racism, disparaging judgments of others or moralizing about others).	**	***	***	**	***	**

	33. Asking questions in order to explore the background of strong emotional outbursts, in order to deescalate the situation and/or to support the participant's own insights into the reasons for his or her own emotional reactions.	**	***	***	***	***	*
	34. Asking reformulating questions in order to support insight into own feelings and needs (e.g. "When you say bloody idiot, do you mean that you are disappointed?").	**	***	*	***	***	*
	35. Asking questions that support awareness and clarification of participants' own feelings and needs.	**	***	***	***	***	**
	36. Asking questions that invite participants to reflect on psychological causality, e.g. emotional consequences of certain behaviors (e.g. "How do you think your children feel when ...?").	*	***	***	?	***	***
	37. Asking challenging questions about a participant's opinions and behavior (when there is a relationship that allows for challenging).	*	*	***	***	***	***
	38. Asking open-ended questions about possible future scenarios, such as "what would you do if your daughter don't want to marry the man you parents find suitable?".	*	***	***	***	***	***
Managing strong reactions, disparaging attitudes and conflict.	39. Being unafraid, open and non-judgmental when participants' have strong emotional outbursts, such as aggressiveness or despair.	***	***	***	***	**	***
	40. Support participants in letting other participants feel and express emotions without trying to distract them.	***	***	***	***	***	***
	41. When someone expresses categorical and disparaging views invite other participants to talk about their experiences and life stories.	*	***	***	***	***	***
	42. Return to and clarify conflict incidents: what happened?	***	***	***	***	***	***

	43. Using mediation situations for supporting awareness of underlying feelings and needs.	*	_	***	***	**	_
	44. Consistently protect and convey values.	***	*	***	***	***	*
	45. Making time for talking through or return to charged issues until the participants have arrived at a natural conclusion.	**	**	**	***	*	***
	46. Inquiring into underlying reasons when some has a negative attitude.	***	_	**	***	**	**
	47. Calling into question and challenging a participant with problematic views, attitudes or behaviors.	*	_	***	***	*	**
Informing	48. Conveying research based knowledge about relevant topics, such as the effects of different types of parenting, facts about the hymen, or homosexuality.	*	***	***	**	***	***
	49. Inform about Swedish laws and about how authorities and other Swedish institutions function.	***	***	***	**	***	***
	50. Informer about and explain citizen obligations and rights, such as paying taxes, notify the social insurance agency, housing allowances.	**	***	*	*	***	***
	51. Informa about widespread views, values and norms in the Swedish society and explain their background.	***	***	***	*	***	***
	52. Explaining aspects of Swedish political conditions (e.g. about the Sweden democrat party's views on immigration and their influence on policies).	**	*	_	***	***	**
	53. Using own experiences and own competence to explain possible consequences of different actions (e.g. regarding parenting or interactions with authorities).	*	***	*	***	***	***
	54. Inviting external speakers, arranging study visits in order to elucidate relevant topics.	***	***	***	**	_	**

	55. Repeating issues that have been treated at earlier meetings and control for understanding.	**	***	***	*	***	***
	56. Informing about how to apply for grants for certain initiatives and about how one might influence political decision-making.	**	*	***	***	*	**
Offering possible interpretations of causal connections	57. Pointing out emotional or other consequences triggered for other participants when someone expresses condemning or disparaging views.	*	–	***	**	***	**
	58. Teaching about models that describe different types of societies: traditional, modern.	–	*	*	*	***	*
	59. Teaching about levels of validation: how to give validation to others.	_	*	***	*	***	
	60. Teach about how feelings of shame arise and what consequences they have (e.g. avoidance of exposure to situations that might trigger shame).	_	_	***	*	***	_
Offering individual feedback	61. Offering individual feedback and advice about personal patterns observed, perceived needs for training and suggestions of strategies and effective behaviors.	*	_	***	**	***	*
	62. Individual sharing and explanation of the leader's own strategies in different types of situations, in order to clarify leadership in concrete situations.	_	_	**	*	?	_
Training skills	63. In due time and scope assigning real responsibilities to participants for various tasks.	–	**	**	***	***	***
	64. Training validation and invalidation.	_	_	_	_	***	_
Working on oneself	65. Being in touch with own state of mind. Noticing own reactions in the present moment in order to be able to take responsibility for managing one's reactions, e.g. by sharing with others what is going on for oneself.	***	?	_	**	***	***

	66. Being aware of and sensitive in relation to power differentials between leader and participants: the leaders are established in the Swedish society, the participants are not.	***	***	_	**	***	***
	67. Train own ability to remain empathetic.	***	?	–	***	***	***
Other themes	68. Being **transparent**: taking care to inform concerned individuals about contacts taken with authorities or other actors.	***	?	***	***	*	**
	69. Using specifically designed and selected **images** as support for conversations about charged issues.	**	**	**	***	***	***
	70. **Using established relationships** in order to get in touch with new participants.	**	*	**	***	_	**
	71. Introducing realistic **role models**, e.g. by inviting former participants to the program.	**	_	***	***	_	*
	72. Referring to **religious** norms: e.g. using quotes from the Koran or Bible in order to reinforce desirable norms and behaviors (e.g. "Only God can pass judgment).	*	_	_	***	_	**

The Prometheus Leadership Commons: A Meta-Framework for Leadership and Leadership Development

Tom Bohinc, Jonathan Reams, Richard Claydon[1]

Abstract: Leadership development suffers a plethora of problems: complexity, competitiveness, pressured stakeholders and unmet needs only start to express the challenges. These issues are suitably summarized by this meta-problem for the subject of leadership: How to navigate the territory? How can a student of leadership, a middle manager, an L&D specialist or a CLO plot a pathway through such a confusing landscape? The Prometheus Project initiated a cross-disciplinary research team to conceptualize a framework that addresses this meta-problem. This paper introduces and discusses the resulting framework, describes our method, and asserts recommendations for expanding the circle of consent for a clear framework for developing the capacities and skills of leadership.

Keywords: Adaptive change, coaching, development, executive, framework, leadership, leadership industry, organization development, performance, personal development, training.

Introduction

Barbra Kellerman summarizes the state of leadership research and practice in direct language; "there is a lot of stuff out there that is less than wonderful" (in Volkmann, 2012, n.p.).

She is not alone in her opinion. Pfeffer (2015) talks about "Leadership BS." Gurdjian, Halbeisen, & Lane, (2014) outlined four key points driving failure in leadership development programs. Beer, Finnström and Schrader (2016) went as far as calling it the "great training

robbery" (p. 3) with global training and education spending reaching $356 billion in 2015 with very little return on investment.

It is our view that the persistence of these issues, despite intense intellectual, emotional and financial investment, suggest that we need a structural shift in leadership development, treating it as an adaptive problem rather than a technical one (Heifetz, 1994, Heifetz, Grashow, & Linsky, 2009; Fritz, 1989). Continuing to invest time and effort to address the issue with more of the same type of resources will not adequately address these issues and may in fact exacerbate the problem. Rather, a structural shift and alternative approach is necessary to see systematically different results.

It was to the purpose of these structural adaptive changes that the concept of The Prometheus Project was conceived on a sunny July day in Barcelona, 2018.

One of the structural issues underpinning the general failures in the leadership development industry is perceived to come understanding of the phenomenon itself. A CEC[2] report (2017) noted a profound confusion about leadership and leadership development. Veldsman and Johnson (2016) wrote: "To the best of our knowledge, no overall, systemic, integrated and holistic view of leadership exists, and few organizations adopt a systemic, integrated approach to leadership" (p. 2). Likewise, Reiche, Bird, Mendenhall, and Osland (2017) summarize that the research literature in this field

> has lacked a coherent and agreed upon classification scheme that helps scholars to clearly describe their research samples, compare and contrast their research contexts and findings with other studies and contribute towards a cumulative and growing body of knowledge about the predictors, correlates and outcomes of global leadership. (p. 564)

Moldoveanu and Narayandas (2019) identify the underpinnings as related to conflicting motivations, a gap between leadership skills, the actual needs of organizations and incomplete learning cycles, in that the skills taught are not transferred or applied.

In our zeal to explore and clarify the essence and features of leadership, we define more and more distinctions and conditional situations for leadership. These are reasonable paths for constructivist learning and both theoretical and applied research, but are not sufficiently realistic for creating a useful body of knowledge for leaders. We cannot express enough our support and appreciation for these explorations. We only counter them with the need for pragmatic effect and the collective responsibility of our profession to be the ones accountable for creating useful constructs, as well as valid ones.

Therefore, it was logical that the first initiative of The Prometheus Project would be to address a framework that could open collective consent across a diverse range of stakeholders around what capacities and skills make up the subject of leading. It sought to create a framework that was simple, valid and generalizable, and useful for any stakeholders, contributors or sponsors of leadership development. From that point-of-consent, the collective influence and ambitions of structural change could advance.

---

[2] CEC is an association representing about one million European managers. https://www.cec-managers.org/

For this, we formed a diverse team of researchers and practitioners to undertake responding to this question:

What would a usable proof of concept for such a framework look like?

This article has two goals:

- To introduce this framework as a simple and digestible tool for a complex group of subjects, like leading, development and the human individual and social identity, and
- To provide the more systemic background of the professional roots of this framework.

Therefore, the article outlines the theoretical and conceptual context that bounded our framework design, describes our method, introduces and discusses the resulting framework, and offers observations and recommendations for expanding the circle of consent for a clear framework for developing the capacities and skills of leadership.

Theoretical/Conceptual Context

Our research draws from several areas that shape the resulting framework. This section covers the theories and concepts we considered most relevant.

The objective of the Prometheus Leadership Commons™ framework is to define elements of leadership that are generalizable and accurate. In other words, they *could* be usefully applied by every stakeholder in any context, including; an organization defining its own development strategies, any individual self-determining their own leadership path, by researchers shifting the blocks and constructs of knowledge and by any of the helping professions who have individual and organizational leadership transformation goals.

We[3] aimed for something that would enable leaders, organizations, consultants or coaches to orient themselves and then to navigate all corners of the capacities and skills of leadership. But also, to open comparisons, contrasts and socialization to enrich the learning process, expand the scope of what is learned and align and influence collaborators as a force for a wide set of use-cases. In simple terms: the framework had to include diverse perspectives, or lenses, so that the result held-up as useful for all of those perspectives.

---

[3] The 'we' here is the research team for this project, (including the article's three authors), which was intentionally assembled to meet these criteria; global footprint, depth in multiple disciplines, diversity of experience/roles that simulate a design-thinking team. The structure of the team included a primary work group and secondary reference and supplemental group. The primary workgroup included experience in qualitative research, including dissertation chair and dissertation committee experience.

Therefore, we had to consider which concepts we would want to test-for-fit and include those in our research. While our considerations went far beyond what is presented here, we chose these four broad themes as necessary contexts for satisfying the goals for the framework.

Personal Capabilities of the Leader

We are still surprised to find how persistently the idea of leadership as solely an executive function holds in day-to-day discourse and thinking, and ultimately shapes the services and business models of the industry. We want to make it explicit that we have framed our exploration with the lens of leadership as an attribute of the person/leader, not as a role or a position in the hierarchy and that the demands of leading may be applicable to any person given a fit to their context. Some leadership demands may be simple, to fit simple contexts. More complex contexts require more complex capacities and skills.

When you read sources on the topic of leadership development, it is easy to notice that there is an assumption that development strategies include strategies for developing the internal capacities of leaders as well as their skills.

Day, Harrison and Halpin’s (2009) approach integrates adult cognitive development theory with the areas of leadership identity and expertise that “appl[ies] to leader development across a wide spectrum of organizations” (p. 4). They note that leadership development implies growth, or change, over time and “includes topics such as personal trajectories, growth modeling, lag times, end states, and a whole host of other related topics. ... [that have] to be as much about development as leadership” (p. 5). Finally, they highlight the need for supporting structures that enable; competency acquisition, leader identity formation, and the process of identity formation that is supported by adult development.

This is further illustrated in Day and Dragoni’s (2015) review of leadership development research. They identify four key indicators necessary for leadership development; leadership self-efficacy, self-awareness, leader identity and leadership knowledge, skills and competencies.

Finally, leaders need to have a high degree of personal wellbeing, focusing strengths of their personal capabilities on their leadership context. For this, we draw on positive psychologists’ focus on wellness, including Csikszentmihalyi and Csikszentmihalyi (2006), Seligman (2002), and Ryan and Deci’s (2017) fundamental motivations.

This framing provided us with key ideas related to attributes for including in our framework.

Leadership as a Contextualized Process

Leadership can happen in any context. Therefore, the framework design would need to show capacities and skills suitable for the agency of leading in any context. Further, a leader would have to assess that context and design their leadership agency accordingly.

The combination of both work and relationship as a context is seen in a number of places. Reiche, et al. (2017), Adams and Anderson (2016, 2019) as well as Warren (2017) all identify capacities for leading work as well as leading relationships. Kotter (1999) defines the practices of leading change to include work and achievement as well as influence and motivation. Kockelman (2007) identifies the elements of agency from a cultural anthropological perspective as both relationship and a process. This is not an exhaustive list.

Other perspectives frame leadership as a process or function, (e.g. Drath, McCauley, Van Velsor, O'Connor, & McGuire, 2008). To illustrate such processes, we utilized Drath et al. (2008), who argue for moving away from an ontological orientation of a leader, followers and a common goal (Bennis, 2007) and towards a process orientation. This means that any activity that contributes to direction, alignment and commitment can be viewed as an act of leadership. Similar sets of distinctions for leadership can be found in Heifetz's (1994) model of adaptive leadership and Grint's (2005, 2010) approach to matching leadership to context.

We also see leaders in a collective creative learning context, as illustrated in contemporary product design practices including design-thinking (Kelly & Kelly, 2013) and dynamic product learning activities such as lean startup (Ries, 2011), leadership in organization crisis (Goldberg & James, 2017) and also in deep traditions of lean and agile transformations where goal, action, reflection, change and iteration learning cycles are a central leadership process (Deming, 2018). Situated with these creative processes are collective leadership constructs that emphasize networks and connectivity across collaborator leaders (Western, 2019).

Finally, a leader can prepare their capabilities but must apply the type of leadership that is required in-the-moment. Their choices of leading must be made based on an assessment of their context.

An illustration of contextualization can be found in Snowden's (2007) model of decision-making. His Cynefin model describes a heuristic for helping identify the type of context one is in. On one hand, there are more predictable contexts, either clear or complicated, but on the other hand, there are less predictable contexts, either complex or chaotic. As well, we often begin in a place of confusion, which triggers a process of identifying what type of context we are in. So, a leader's capacities and skills must be suited to predictable challenges, but also dynamic uncertain extremes.

The framework design considers that leaders (and the participants in the development of leaders) require the capabilities to assess the context that they are leading in and respond by employing a variety of collaborative modes and resources as aids to navigate their decision-making, capability development and deployment and interventions.

Learning as a Leadership Capacity

One of the aims of the framework is to enable learning experiences that develop leadership both individually and collectively. The framework's organization, levels and distinctions are constructs to support finding salient and relevant learning objectives for individuals, sponsors, program designers, and experience designers.

The framework is not only a learning and development tool, but also includes learning as an element of leadership capacities and skills. The processes of learning and the processes of leading are seen to be inseparable.

Learning theory and learning models weighed heavily in our design. The resulting framework had to address several learning-related challenges. These include; the personal capacity to learn as a capability of leaders, the process of leading includes learning as an intentional outcome and leadership development is a complex process inclusive of short-term acquisition, short-medium term integration, and long-term development and integration.

Meeting this list of criteria became an important element of the Prometheus Framework.

We approached learning based on Fischer's (1980; Fischer and Bidell, 2006; Mascolo and Fischer, 2010) dynamic skill theory and Dawson's (2020; Dawson and Stein, 2011a, b) virtuous cycles of learning (VCoL) model. Learning is understood as incrementally making connections with existing knowledge and skills by setting appropriately challenging goals, gathering relevant information, applying it to real world challenges and reflecting on outcomes to build new skills.

Motivation for learning can be seen in terms of the dopamine opioid cycle, where goal setting stimulates dopamine production which stimulates incentive salience (Berridge, 2007), motivating one to meet a challenge. Achievement of the goal releases opioids, our reward for the effort that makes it easy to reset the goal and to go around the cycle again (think of an infant learning to walk). Applied to learning and leadership in adulthood, the cycle enables us to reconnect to our natural learning experience and becomes the engine of leadership development.

Development Strategies

The framework has to be useful in the process of setting leadership development strategies with both short-term and long-term trajectories.

Building a leader's capabilities is a continuing journey, which can start at a young age. Navigation through development is unceasing, as outlined in Vaill's (1996) discussion about learning to navigate modern leadership challenges. Leadership development includes psychological development, which is masterfully synthesized by Basseches and Mascolo (2009).

Roux (2020) identified life-long learning as a key theme for leadership. She concludes that leadership adequate for the 21st century is;

> integrative, complex and multi-layered. There is a need for lifelong horizontal and vertical development journeys using adult development theory, virtuous cycles and neuroplasticity as core theories of continuous growth. Leadership needs to be scaled to enable work in new contexts of digital, virtual and flexible environments that are in constant flux with wicked problems that can only be solved collectively. (p. 30)

Stage-based interpretations of leadership (e.g. Kegan and Lahey, 2016; Torbert & Associates, 2004; Joiner and Josephs, 2007; Kuhnert and Lewis, 2006) spotlight a significant practical problem. These models all note that very few people, perhaps no more than 2-5% of the population, ever achieve the highest levels of adult development, which correlate with leadership having the capacity to best address the most complex challenges. Collins (2007) writes that only 12 of the 14,000 leaders he observed reached his criteria for a Level Five leader.

This premise spotlights a number of issues related to leadership development strategies.

- First, development processes to these higher levels take a long time, are too costly and too risky for many companies experiencing the war for talent and retention.

- Secondly, organizations must be able to map the leadership competencies of job-hoppers, new members and joint-venture members, so they can rapidly deploy and use them.

- Thirdly, with a limited supply of high-functioning members, rigid traditional deployment practices, there is likely to be ever more frequent capability mismatch conditions between individual leaders and their contexts.

- Therefore, you almost certainly need to engage in real-world challenges with the leaders that you have, not the leaders that you want.

In summary, the framework should allow for flexibility in development and maintain utility for these real-world complex challenges where development may be likely across the lifetime of the leader, but at the same time they are called to lead in the moment, ready-or-not.

Methodology

Mortimer Adler was faced with a similar dilemma to ours in the field of western philosophy, which spurred a lifetime of scholarship. When faced with the problem of existing terms being irreconcilable, Adler (1967) took on a necessary re-synthesis of topics in a process he called “syntopical analysis” and “coming to terms.” Literally, the process of choosing the best unifying terms across complex seemingly disconnected diversity.

Constructivist Grounded Theory

Our research was designed as constructivist grounded theory (CGT) (Bryant, 2017 & 2009; Charmaz, 2000; Corbin & Strauss, 1990; Mills, et.al., 2006; Thornburg & Charmaz, 2010). Bryant (2017) asserted that insightful research adopts one or more methods that are complementary to their specific project context. Our CGT adopts contemporary deliberative practices of Collective Intelligence (Engle, et al., 2014), lateral thinking (De Bono & Zimbalist, 1970) and creative problem solving (Treffinger, 2005).[4]

---

[4] Much of our method included leadership and development theory and to that extent our methodology also followed the steps of meta-theory as a method (Edwards 2010) and certainly shares the intentions of that school of theoretical research.

Bryant also asserts that while CGT can vary in its details, it should be consistent to its core elements. In an interview late in his life, Strauss, one of the founders of the grounded theory methods, identified three elements necessary to meet grounded theory requirements (Legewie & Schervier-Legewie, 2004). Our research addressed each of these:

- Theoretical sensitive coding. This means that there is a strong instinct and capacity to ‘listen’ to the essential stories underlying the ground, and to construct useful parts to be used in sense-making and organization of the ground (data).

- Theoretical sampling. This means choices of data are well considered to advance the learning and creative formation spiral.

- Comparison. Choices for what to compare are fearless so as to stretch the theories, test them, sharpen thinking, and cull bias.

The mechanics of CGT have been described as a spiral (Mills et al., 2006) of learning and discovery that materialize with many variants. Our spiral is expressed as:

- Green-field. Theorizing (as much as feasible) without bias or pre-condition of existing structures.

- Sample. Data which can be any kind of source that informs the theoretical process.

- Conceptualize. Building the linguistic labels, from which an overall theory will be constructed, technically referred to as ‘coding.’

- Frame. Positing exploratory and partial concepts and segments of theory, technically referred to as ‘memoing.’

- Form. Expanding or synthesizing a more integrated theory or model.

- Test and Compare. Constant comparing and lateral thinking to cull out bias, pre-conception and refine thinking and articulation of the theory.

While inductive and deductive reasoning are prevalent as part of the creative process (Treffinger, 2006), CGT especially emphasizes the essential process of *abductive reasoning* in which the theorist creates the simplest and most likely explanation for making sense of the grounded observations. This result is “plausible and useful” (Bryant, 2009, np) but is qualified as uncertain or provisional pending experience and confirmation in use.

How do you know how flexible your process mechanics should be? CGT practitioners consistently remind us that the *principles* of the process are primary to the *mechanics*. Balancing orthodoxy with the pragmatic, if your sources are reams of paper, emails or physical evidence, then meticulous tagging and organization are a pragmatic requirement to make sense of the data. In our methods, we adjusted to the age of virtual communication and collaboration and leverage the practices and technical tools to conceptualize and frame our primary, secondary and tacit knowledge into discrete parts. We were intentional, conscious and methodical, but also agile and pragmatic.

How do you know when you are done with spiraling? Following Eisenhardt (1989), our perspective is that you are sufficiently done when you have consistent experience as you test and compare. In other words, “we have seen this before” or “this fits well.” Interdisciplinary comparisons led us to conclude sufficient consistency to warrant a release of the framework, opening further experience and confirmation in practice and research.

Data Choice and Theoretical Sampling

Our data and theoretical sampling included three classes of sources. First, the intentionally diverse experience of the research team, second, a selected extended reference group to provide feedback for bias and critical thinking, and lastly, published and unpublished scholarly work, selected based on preliminary rounds of analysis (see below).

The analytical team members hold two PhDs and three Masters, have decades of practice in leadership development, education, business transformation, coaching, training. Members have engaged in thousands of leadership development interactions from the role of coach, organization sponsor, executive, development professional, researcher, and educator. They have depth of knowledge across disciplines and roles in the leadership development context and have methodology experience with dissertation chair and committee experience. Members were located from Asia, Europe and North America. All were English speakers.

The extended reference group included some who were not available sufficiently to the process, so became ancillary resources. In other cases, these resources represented specializations that we targeted for exploration.

Cross-disciplinary theoretical comparisons included; learning objectives and processes in learning theory, from Bloom (1956) through Gagné (1985) to Dawson and Stein (2011a, b), psycho-therapeutic development objectives synthesized across the major psycho-therapeutic disciplines by Basseches & Mascolo (2009), leadership development practice from the US Army, (e.g. (Day et al., 2009)) whose programs range from the ranks to top echelons (Gavin & Watson, 2019), executive leadership education from Moldoveanu & Narayandas (2019) and finally, leadership assessment models of Anderson & Adams (2016, 2019) and Warren (2017) which infer leadership attributes and developmental factors from observed traits.

Pedagogical Considerations

Pedagogical learning objectives and pedagogical sequence were weighed to support the clustering phases and the cohesiveness of the framework groupings. The framework is intended to facilitate setting and sequencing learning goals and objectives from general to detail/micro-learning and from fundamental to advanced development objectives. Here, we also weighed usability as part of strategy and design of leadership development programs.

Theory Finalization

Comparisons and refinement are a key part of meta-framework finalization. To this end, each team member applied the framework in small field-tests or reviewed the framework with peer advisors and experts to gauge any indications of change or refinements. In addition to the peer/expert feedback, the frameworks' systems and subsystems were cross-referenced to a sample of independently defined inventories of leadership development and curriculum subjects from public and private executive development programs. Notably, we leveraged the extensive anthologies of leadership knowledge from Bass (2008) and Nohria & Khurana (2010) to confirm the grounded field of our consideration and inform design choices.

In finalizing the framework, the structure evolved from an initial three to five and then six meta-categories identified as leadership systems and spanning the whole of the leadership phenomenon (figure 1 below). The same process was used to further divide these system categories into a second level of detail sub-systems (figure 2 below). We held a constraint of no more than five of these subsystems in each of the six level meta-categories. This constraint was not easily fulfilled, but ultimately led to satisfying abstractions that can have resonance across the stakeholder spectrum, from academic, to clinical to popular consumption.

This research did consider many samples to form a hypothesis of the nature and composition of a third level of detail in the framework. However, we did not attempt an inventory and organization of the large number of leadership topics that fit into level 3 and defer this to further research. However, we did define this level in the framework.

It is our view that the framework meets its goal of providing simple, valid and generalizable (useful) meaning-making that can open communication and hold focus on these complex topics which are otherwise often deflected or bogged-down. Our goal is a semi-stable standard reference that is usable by all stakeholders and that allows orderly evolution. We invite engagement and refinement as we expand the circle of contributors and the complexities of the level 2 and 3 domains, what Kockelman (2007) refers to as flexibility and accountability.

Results

We express the research results as the Prometheus Leadership Commons$^{\text{TM.}}$ framework (PLC):

- "Prometheus" because it represents "forethought," the Greek archetypal meaning.
- "Leadership" because this is the concept that we wish to unchain and maintain.
- "Commons" because, even as it is facilitated and governed by a central organizing group, it is framed to become the shared open-source framework for all stakeholders' uses.

The PLC framework is structured in 'levels' with the first level showing 6 meta-categories, grouped between inner capacities and adaptive behaviors. Categories A, B, and C are personal capacities of leadership.[5] Categories X and Y are skills adaptive to engaging in contexts of leading relationship or task. Category Z are the skills adaptive to the action of leading.[6]

Level 1 is useful in application and should not be seen as only a way to organize lower-level details. Its simplicity belays its approachability and easy navigation power which opens conversation, comparison, deconstruction and exploration (see figure 1).

Developed Inner Capacities
Skilled Adaptive Behaviors
A. CAPACITY TO BE
X. ENGAGE PEOPLE
B. CAPACITY TO KNOW
Y. ENGAGE CHALLENGES
C. CAPACITY TO LOVE
Z. LEAD RESULTS

Figure 1. Prometheus framework level 1.

That simple and easy navigation is even more valuable because it supports confident exploration into additional details found in level 2 and level 3. This layering allows explorations with more granularities for each area while keeping confidence in the relationship to a whole system of a leader's capacities and skills.

Level 2

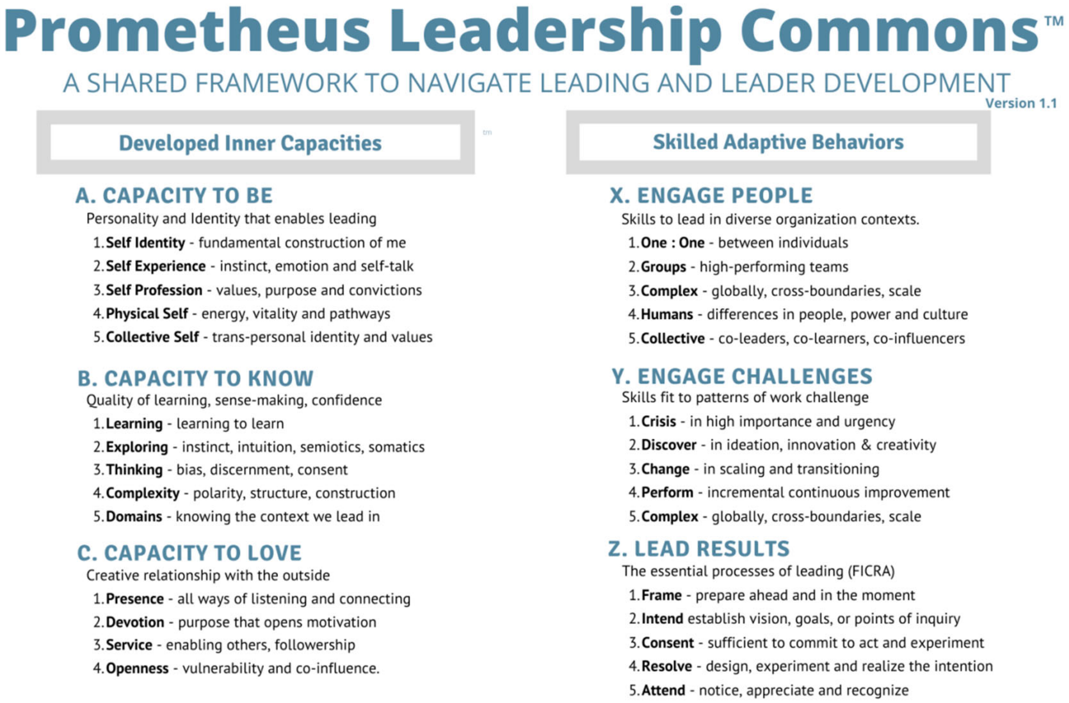
Level 2 shows twenty-nine sub-categories (or subjects) nested within the level 1 meta-categories (see figure 2). For each of the level 1 systems, there are 4 or 5 subsystems (or subjects). Examples of the subsystems include one-to-one engagement skillsets vs. the skills to engage in groups.[7]

---

[5] The most unique category (relative to comparative frameworks) is the Capacity to LOVE (to be gracious or serving) and is the 'object' of our self-consciousness in contrast to the Capacity to BE as 'subject.'

[6] We observe that many resources on leadership express differences in practice or types of leaders, but not as frequently express the act of leading. In the PLC LEAD RESULTS domain frames this. The primary sources for the LEAD RESULTS domain is a synthesis of the essential practice of leading from well-researched models including Adaptive Leadership (Heifetz, 1994), Change Leadership (Kotter, 1999), social anthropology concepts of agency (Kockelman, 2007), and learning cycles of Dawson and Stein (2011a, b).

[7] There are some PLC sub-systems that may stand out against convention and are invitations to mainstream as well as fringe ideas if they are substantiated and rationally articulated. These include a category for collective transpersonal identity which may include spiritual traditions, physical capacity that



Prometheus Leadership Commons™

A SHARED FRAMEWORK TO NAVIGATE LEADING AND LEADER DEVELOPMENT

Version 1.1

Developed Inner Capacities

A. CAPACITY TO BE

Personality and Identity that enables leading

1. **Self Identity** - fundamental construction of me
2. **Self Experience** - instinct, emotion and self-talk
3. **Self Profession** - values, purpose and convictions
4. **Physical Self** - energy, vitality and pathways
5. **Collective Self** - trans-personal identity and values

B. CAPACITY TO KNOW

Quality of learning, sense-making, confidence

1. **Learning** - learning to learn
2. **Exploring** - instinct, intuition, semiotics, somatics
3. **Thinking** - bias, discernment, consent
4. **Complexity** - polarity, structure, construction
5. **Domains** - knowing the context we lead in

C. CAPACITY TO LOVE

Creative relationship with the outside

1. **Presence** - all ways of listening and connecting
2. **Devotion** - purpose that opens motivation
3. **Service** - enabling others, followership
4. **Openness** - vulnerability and co-influence.

Skilled Adaptive Behaviors

X. ENGAGE PEOPLE

Skills to lead in diverse organization contexts.

1. **One : One** - between individuals
2. **Groups** - high-performing teams
3. **Complex** - globally, cross-boundaries, scale
4. **Humans** - differences in people, power and culture
5. **Collective** - co-leaders, co-learners, co-influencers

Y. ENGAGE CHALLENGES

Skills fit to patterns of work challenge

1. **Crisis** - in high importance and urgency
2. **Discover** - in ideation, innovation & creativity
3. **Change** - in scaling and transitioning
4. **Perform** - incremental continuous improvement
5. **Complex** - globally, cross-boundaries, scale

Z. LEAD RESULTS

The essential processes of leading (FICRA)

1. **Frame** - prepare ahead and in the moment
2. **Intend** establish vision, goals, or points of inquiry
3. **Consent** - sufficient to commit to act and experiment
4. **Resolve** - design, experiment and realize the intention
5. **Attend** - notice, appreciate and recognize

Figure 2. Prometheus framework levels 1 and 2.

The X Y Zs

There is a daily deluge of posts, promoted content and publications on leadership and leadership development on our sites and in our inbox. We easily find discussions across the rainbow of leader models (authentic leaders, transformational leaders, adaptive leaders, vertical leaders, situational leaders, etc.). It is also easy to hear exhortations to discover our purpose, center our being, to explore either our strengths or our innermost fears.

It is rare to find a simple description of what we are doing when we lead. Yet, this is the basic focus that any of us must hold as we engage in the agency of leading – or as we orient ourselves for learning and development.

We include that description of what leading is in the PPLC as level 1 domain of (Z) LEAD RESULTS (figure 3 below). Even though the authors normally eschew clever acronyms, we did articulate FICRA as the mnemonic for this domain (and it is hardly clever!).

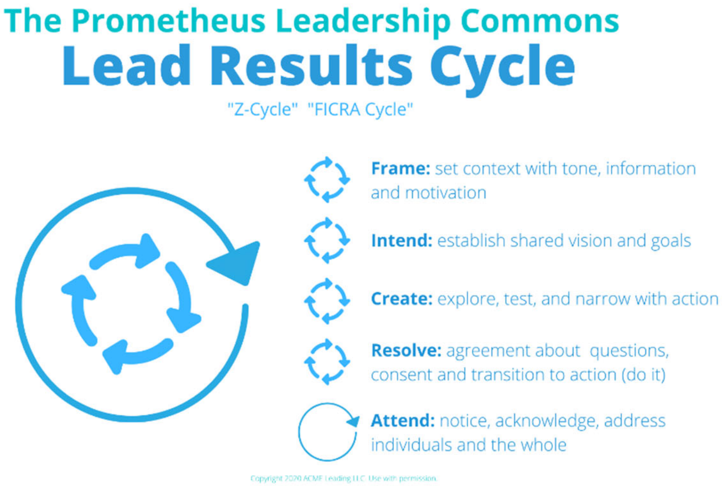
But, we like it because a mnemonic is good for quick recall.

We hope that supplying this mnemonic will help anyone maintain clarity in the heat-of-the-moment, when *all* of the leader's faculties may be challenged by the heat or complexity of the work and people at-hand.

---

includes connection to the idea of personal energy fields, instinct and intuition as a component of intelligence, inclusion of business or technical domain knowledge as a leadership attribute, the reality of people, culture and power as a context, and the identification of love as a leadership capacity.

Two further domains in the X Y Zs grouping are (X) Engage PEOPLE and (Y) Engage CHALLENGES (see figure 4.). They represent skills for relationships and for work, respectively. Considering development sequencing, some of these are markedly cumulative. For example, engaging one to one (commonly referred to as 'people skills') includes skills as diverse as listening, feedback, feedforward, coaching and the less intellectual practices of touch, presence or even eye-reading. Yet, these skills are also foundations to more complex engagement, in a group or team and potentially across more globally diverse and complex relationships.



The Prometheus Leadership Commons
Lead Results Cycle
"Z-Cycle" "FICRA Cycle"
Frame: set context with tone, information and motivation
Intend: establish shared vision and goals
Create: explore, test, and narrow with action
Resolve: agreement about questions, consent and transition to action (do it)
Attend: notice, acknowledge, address individuals and the whole
Copyright 2020 ACME Leading LLC. Use with permission.

Figure 3. The lead results cycle.

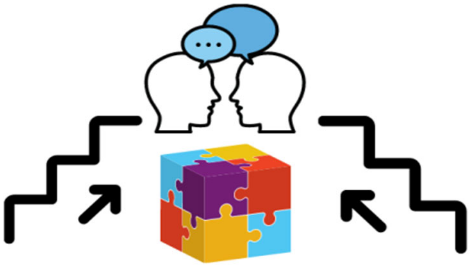


Figure 4. Engage people and challenges.

The Engage PEOPLE domain includes two higher-order subjects.

Humans includes the skills to assess and adapt to the human context for leading, including your individual constituents, and the constraints (or enablers) of power, politics and culture. The framework sees them as realistic contexts that leaders-on-the-ground struggle with every day. In our thousands of leadership development interactions, we find that members of the profession prefer the soft subjects such as inner discovery and affirmative relationships, while our clients – from the front line to the boardroom – are living in the rougher reality of teams, organizations and communities. The framework asserts both of these perspectives as necessary for effective action.

Collective includes the skills to learn, decide, act, reflect and lead *collectively* in order to be effective in the moment and in real-world contexts. These collective skills may be the most important emphasis in the framework and least in-focus across leadership programs.

Taken as a whole, these five Level 2 domains create a very rich and robust span of skills related to the engagement of PEOPLE in the dynamics of leading.

The Engage CHALLENGES domain, (figure 5) identifies skills for four archetypal patterns readily found in teams, organizations, industries, networks, or communities regardless if they are for commercial, altruistic, civic, political or social purposes.

Figure 5. Engage challenges.

In addition to these basic four patterns, there is a fifth subject in the CHALLENGES domain that focuses on skills for leading work in contexts that are more complex than the norm; such as combinations or parallels of the four basic patterns, which are often mixed in real-world complex settings. For example, crisis, operations and innovations may be simultaneous challenges.

Of all of the domains of the PLC, this set most reflects executive business thinking and skills which we place in the realm of positional leadership across a wide range of contexts.

The A B Cs

The level 1 A B C capacities of BE, KNOW and LOVE, (figure 6) are about personal development, versus skills and behaviors, or versus simply holding *knowledge about* those capacities.

The A B C domains support what Krathwohl, Bloom and Masia (1962) would identify as affective learning objectives as contrast to cognitive or operational. The strategies for developing these leadership capacities do include supporting objectives of *learning about* these concepts, and putting them into practice, but in support of the primary objectives of *internalizing* these capacities.

BE
LOVE
KNOW

Figure 6. The A B Cs.

The framework also considers *the combination* of these three domains as how the leader constructs their identity-as-a-leader, beyond their self-identity as a being. So, the self, (BE) is also component of the leader's identity, which includes the components of their relationship to knowledge (KNOW) and the outside (LOVE).

Capacity to LOVE is the leader's relationship to "the outside." This part of the framework includes the concepts of dedication to purpose and learning, selflessness in relation to the other, but also their openness and being affected by the other. This progression is consistent with adult maturity stages that are conventional and post-conventional, where the leader's consciousness extends from themselves to things and others-beyond-themselves.

Capacity to BE is very much the range and balance of self-experience of the leader, as is richly expressed in psychological lenses. In addition, it provides two areas that are not often emphasized in leadership development. The first is Physical dimensions of leader self-experience. The second is the Collective dimensions of self-experience, or trans-personal consciousness.

Finally, the Capacity to KNOW is the leader's capacity to have a relationship with knowledge, with truth and bias, polarity and paradox, and with the continuing experience of learning. There two subjects that stand out from the conventional leadership content: the challenges of complex knowledge and the place of domain knowledge as an attribute of a leader.[8]

Ultimately, the framework wants to lead the learner to a place of harmony and integration across all three of these domains, as what we experience in ourselves and bring from ourselves to the process of leading.

Sequencing and Complexity

The level 2 sub-systems are defined with sequence and hierarchical complexity in mind, where earlier subjects can be prioritized differently from more advanced or complex development subjects. For example, in the skill domain of Engage PEOPLE, there are two early subsystems (one: one and group) that easily illustrate a sequence relationship, where mastery of the former is a substantial prerequisite for the later.

Level 3

The PLC framework acknowledges the vast number of topics in the knowledge-sphere of leadership and provisionally created the construct of level 3 for them. We classify the elements for level 3 as topics or composites; *topics* being made up of single subjects that are seen as first-order constructs used for higher-level abstractions as well as for assembly into composite elements and *composites* made up of compound and complex attributes that may even span the level 1 categories and level 2 subjects.[9]

These topics and composites were part of the research ground used to conceptualize the meta-structures of the PLC framework. The sheer numbers, and the absence of an aligning or comparative framework, make these difficult to adopt and integrate – so the PLC framework is a way to organize as well as open a more integrated view.

The framework, in its current version 1.1 does not attempt to fully inventory all possible level three topics or composites. However, some of the level 2 subject descriptions do provide a good set of examples of what they might be. The subject of Exploring, within the Capacity to Know includes the specific topics of; instinct, intuition, semiotics and somatics, which make a very suitable inventory of what would be level 3 topics in this sub-domain.

---

[8] We had some discussions about if bundling the Capacity to Know with Be and Love was the right framing and noted that many in the industry see intellectual and cognitive capacities as skills or see them as distinct from personality, emotion and relationships. It became clear to us that this combination in the internalized domains was one of the biggest values in including cognition, truth and knowledge as intimately human and internalized experiences.

[9] An example of a composite element may be the popular concept of "grit," which may be composed of topical elements such as emotional maturity, persistence, goals setting and holding dedication to principles.

It *may* be valuable to organize or catalogue these further, articulating explicit relationships and sorting the more valuable from the questionable. Some of this may be explored in further research and in The Prometheus Projects' structured communities and initiatives.

We do not see this kind of complex analysis as a pre-requisite to the framework's value, and it may be unrealistic and unnecessary. There is evident value in being able to traverse between a given topic or construct and contextualize them. This traversing and contextualizing is a valuable learning and communication practice.

Walkabouts

This framework with two simple divisions, six major domains and twenty-nine sub-domains (or subjects) is both simple and complicated. As you test and digest it, you likely will need to adjust your incumbent thinking and make new comparisons and contrasts. Some areas of the framework will be familiar, others highlight new connections and still others unrecognized gaps. This kind of opening awareness, contextualization and re-combination is exactly the navigation that the framework is looking to serve.

We also assume that the PLC framework is new content for anyone reading this article, so some illustrations (in lieu of conversation) would help move it from strange to familiar. We offer just a few of these (reference figures 3-6).

You can read figure 1 from upper left to lower right, as if it were a shipping manifest. However, we recommend reading top-to-bottom from top layers to lower detail, and from the lower right (starting with Z).

Top-to-bottom simply means that you consider the inner capacities and adaptive skills as useful navigational constructs to explore and to explain. Try thinking or conversing just with those. You might ask: "What part of this leadership subject is about inner capacities and what part is about adaptive skills?" We have found that this question and the simple discussion it invites are helpful.

Then, try the ABCs and the XYZs. As a group, how many examples can we find for each of these domains?

Starting from lower right, LEAD RESULT, offers the perspective of observation of the leader in action, and the development needs that might illuminate. Try asking questions such as:

- What inner capacities (or adaptive skills) do you draw from when you (insert one of the FICRA subjects)?
- How do your adaptive skills and inner capacities serve or derail the action of leading?
- Where are your strengths and which areas may be under-explored?
- What areas might you co-lead as a 'spiky'[10] strategy?

---

[10] See elaboration of this concept below.

From here, you can naturally walk back through the framework for exploration as development goals or co-leadership strategies. This walk back might be facilitated by developmental assessment techniques, coaches or mentors.

Another illustration of applying the PLC framework is our conversations around the immunity to change (ITC) process for leadership development with Minds at Work.[11]

The ITC process includes a first step to set personal commitments or improvement goals. The insights for setting these goals often come from self-reflection, strengths and weaknesses feedback, psychometric and 360 assessment results. However, these also always need the subject to make some kind of self-assessment and to make a choice; and this can be difficult without a context of what a leader and leadership means.

For example, an assessment of 'low on big-5 openness' is a useful fact, but abstract in terms of what behaviors one may want to change. The PLC framework points to skilled adaptive behaviors in leading. For example, how do I 'attend' to the participants in the action of leading? What 'attending' behaviors do I see (or not see) that I want to change? Then, further along the ITC process, the explorations of the framework's inner capacities can also aide the exploration of immunities and hidden assumptions about that specific area, such as exploring intuition or devotion to others or principles.

A third illustration addresses the hypothesis that the framework might help to better sort the good from the not-so-good from the leadership echo-sphere.

I recently watched a presentation from a high-profile practitioner on 'centering practices,' that was part of a new leadership development product from an established consultancy. It introduced some popular thoughts about neuroscience (cortisol, testosterone, oxytocin), asserted that leaders should build a habit of 'centering,' and spoke about (more than demonstrated) techniques "so that cortisol can be reduced and ("not too much") testosterone and oxytocin can be released" and finally included a fair amount of asserting that 'centering' should be more prevalent.

Anyone watching might experience a range of satisfaction or tension from the presentation, but few would be able to understand what they did not already know or believe about why it was included in a session on leading, or to understand or repeat the techniques so they can be transferred to behaviors and internalized. Of course, I have re-watched this segment a half-dozen times, wearing my best humble learner hat. Still, I find it wanting as a communication or a development experience.

How might walking through the framework help navigate this?

The simple answer is that having a persistent shared mental framework gives you a context to understand and evaluate some bit of content that may come your way. I can better understand criteria for quality. I can better think critically (logically) about what I am presented. I can better engage and ask questions. I can more quickly determine: Is this worth my time? Is this going to hold up politically and experientially in my organization if I spread this content? Can I bring this to a better place? If not, I can feel good about walking away.

---

[11] Unpublished conversations with Deb Helsing Ed, Co-director, Minds at Work. Minds at Work are the authors of the ITC process and providers of certifications and consulting services using the ITC model.

Finally, with the framework as a context, I can ask: How does the concept of ‘centering’ or ‘mindfulness’ fit in to this PLC framework?

Here is a quick summary of how we might ‘connect the dots’ with the PLC (with the strongest connections first):

> (Z) LEAD RESULTS includes the skill of *framing*. A leader may choose to apply the ‘centering’ skills to prepare themselves or the group to be attentive to the dynamics at hand.
>
> Capacities to BE, KNOW and LOVE are about what you (the leader) bring to (the action of) leading. ‘Centering’ practices (mindfulness, clearing) are leader-capacity practices. There is a direct relationship, with PLC subjects like self-experience, physical capacities, exploring, and presence.
>
> (X) Engaging PEOPLE and (Y) Engage CHALLENGES are leader-member exchange skills and process leadership skills categories. This is a fine point of communication about traversing the framework. Yes, you bring your inner capacities as a leader to the action. So, yes, you may bring personal mindfulness capacities to this action. Yes, skills of mindfulness may be part of your affective development. But, these parts of the PLC highlight skills-based engagement. They are compartmentalized in the framework but exist as a whole in actual experience and practice. They are distinct in the PLC so that you can (remember to) (better) make the distinctions and can design learning and development at incremental (micro) levels.
>
> Do these walkabouts illustrate that the framework has value for navigating?

We think that they do and that it does. A framework does not eliminate the complexities, paradoxes or subtleties of these subjects, nor does it eliminate the flaws that many encounters may include, but does help you walk-through them, make distinctions and contrasts, expose your learning edges and bound the scope of your collaborations.

Finally, consider the value of the framework with a group of like-minded peers. You may find some rise in enthusiasm and a new sense of alignment as you explore perspectives with this new framework. But also consider a group of participants from diverse backgrounds, and little common ground. Without the framework, this group could be quickly lost.

Discussion

Language

The framework is intended to help navigate the complexity of leadership and leadership development. It helps to answer these kinds of questions:

- What part of leading are we talking about?
- What part of leading are we observing?
- What part of leading does this program address or not address?
- What do executive leaders and front-line leaders have in common and what distinguishes their leadership capacity?

The language used for the framework has to be pragmatic in a few ways; first, to be sufficient for consent by a wide spectrum of stakeholders; second, to allow for sensible use in everyday language in any context; third, to allow for flexibility and its evolution.

We have tirelessly worked to choose terms that can be used in conversation. In some cases, we found a great fit and in other cases learned that no single term is perfect. So, we think using these terms is important, but that there is room for alternatives, aliases and evolution. To borrow from Waterman and Peters (1982), the language of leading and development requires 'simultaneous loose-tight properties.' The right terms should fit the context, but without losing the rich meaning in the minds of the stakeholders.

An illustration of language differences that might be opportunities for opening communication is one practitioner we observed using the terms 'emotion and cognition' in a similar way that we speak about BE KNOW and LOVE. Our perspective is that, for a comprehensive framework that covers all the corners but also all the levels of maturity, we have correctly positioned the concept of emotion less prominently than this practitioner has. Emotional awareness and processing our emotional self-experiences are important capabilities, but they are only a part of what we see as the self-experience of the leader.

Terms Across Disciplines

We chose terms from the education profession that we realize may be confusing to some readers, as a central organizing criterion for the level 1 domains. We think this is worth addressing.

We recognize that many conflate the terms 'affect' and 'affective.' Affect is a term in psychology that aligns with the term 'emotion,' which is also part of the common dictionary use of the term. In the PLC framework, when we talk about the sub-domain of 'self-experience,' we are including what the psychologist would speak of as 'affect.'[12]

Affective is a term from learning theory (Krathwohl, Bloom and Masia, 1962) to describe a specific class of learning outcomes. Affective learning outcomes are not emotions, per se. They are internalized experiences of any content. A Jungian may talk about ‘individuation’ of experience or knowledge.[13]

---

[12] Affect is also a verb with two meanings. We use neither in the PLC. First is taking on a false persona or emotion, and we do not use the term in that sense. Second, as the pair to 'effect.' In the simple case 'affect' is the object in the sentence and 'effect' is the verb and would be the fair synonym of creating an outcome or result.

So, the ABCs of the framework are grouped as such, because they all have affective learning objectives for leader development. Even commonly thought of cognitive subjects such as ‘domain knowledge’ define primary developmental outcomes for these areas of the PLC framework and as such are *affective,* in Bloom’s sense of the word. In the case of domain knowledge, it is awareness of the capacity and commitment to building it, vs the gathering of specific knowledge content.

The Work of a Framework

To examine why leaders are failing to engage with the more rigorous leadership models, or why practitioners and consultancies continuously re-invent and reduce leadership into consumable bits, it is useful to turn to an older idea that is still true.

In Weick’s (1979) observations of organization studies, he argued that there were three types of organizational texts.

1. Simple and generalizable, but not accurate (reductionist)
2. Simple and accurate, but not generalizable (narrow, un-contextualized)
3. Accurate and generalizable, but not simple

Any text that tried to be all three (simple, accurate and generalizable) tended to contain little useful advice and lots of regurgitated clichés. We suggest that leadership industry content in 2020 is in much the same state.

Leaders in 2020 are drowning in the complexity. In such situations, humans are biased towards reaching for simple stories that feel right and protect their sense of self, shutting out and closing down information coming from challenging or critical sources. Consequently, the aspiring leader of 2020 tends to be drawn towards simple stories that are inspiring, but either not accurate (e.g. Simon Sinek’s (2009) *Start with Why*)[14] or not generalizable (e.g. leadership biographies). Cognitively and emotionally overwhelmed, they reject the more complex, accurate and generalizable texts and theories, and can regard those suggesting and producing them as threats or fools.

---

[13] In contrast, knowledge/skill are in described by Bloom as ‘cognitive’ outcomes; where high-functioning outcomes might be described as ‘evaluation’ or ‘synthesis.’ Similarly, this concept is confused with the notion of ‘cognition’ in psychology and learning theory.

[14] Sinek’s focus on purpose is appealing yet can leave many feeling unfulfilled. As well, balancing inspiration with access for implementation and worthiness of purpose is more complex than Sinek makes it out to be. Further, Sinek’s approach has been critiqued as oversimplifying complex topics such as neurobiology and being overly selective in choosing evidence to support his claims, (such as the Wright brothers vs. Langley first to flight race, where Sinek focuses on the Wright brothers having a *why* while Langley is characterized as being after fame and riches. Yet evidence shows institutional constraints as well as a lack of sharing information from the Wright brothers were among the many factors involved).

This state of affairs is not helped by business schools tending to employ simple and accurate case studies that leave students with little access to the deeper more complex meta-frameworks that do provide accurate and generalizable models of leadership. Leadership development providers tend to be locked into simple and generalizable theories of leadership that, while perhaps contextually appropriate to the time they were written (e.g. transformational leadership in the 1970s and 1980s), fail to accurately address the challenges of the real world. Finally, the "business guru" publishing phenomenon, initiated by Tom Peters' solo career after *In Search of Excellence*, has resulted in a completely deregulated market of simplistic, silver bullet "solutions" that do more harm than good.

We hope our framework will allow the aspiring leader, the humble practitioner and the researcher, to develop the capacity to critically determine the value of a leadership text or development program, and appropriately categorize it, while simultaneously being able to extract valuable ideas that are contextually relevant to their specific leadership situation and developmental state.

Collective, or *Spiky* Leadership

To be effective, universal and adaptive, leadership strategies will maintain three complementary but distinct practices: long-term and just-in-time *development* and a flexible leadership *deployment* strategy.

Short-term *development* strategies will focus on more easily adopted and integrated subjects, which pragmatically means they focus on the XYZ skills domains, on leveraging individual strengths in the ABC domains and set those development experiences in a context where they can be real-world applied and socialized.

Long-term *development* involves the life-long navigation of individuals with the potential goal of reaching the higher levels of leadership outlined in stage-based models. For this to be useful, three things need to happen.

- The locus of long-term development cannot only be with the organization.
- Members must be able to plan their own developmental journey and take it with them as they change organizations.
- Lastly, objectives for development need to encompass an assumption of flexibility and agility about leadership itself.

A just-in-time *deployment strategy* relates to the possibility of being able to select and rapidly deploy contextually appropriate co-leadership teams to emerging leadership challenges. Implementing these co-leadership teams requires a change in the concept of leadership (that we have dubbed *spiky leadership)* where a much greater emphasis is given to collective leadership capacity realized through the aggregation of individual 'spikes' of talent or competency into co-leadership alliances that are creatively selected, deployed and dissolved as and when needed, a variation on the idea of lead-with-the-leaders-that-you-have – co-lead-as-you-need.

The notion of *spiky leadership* is already visible at a popular consciousness level. From children's cartoons, such as *Paw Patrol* and *Teen Titans*, to the deeply drawn fantasy of the *Game of Thrones* books and TV show and the comic-inspired *Marvel Cinematic Universe* and *The Walking Dead*, we see exceptionally talented but flawed people come together in teams to solve problems beyond the capacity of any single one of them. Within the long narrative arcs, we also see significant character development as individuals wrestle with their flaws, such as Tyrion Lannister's poor sense of self-worth and deep cynicism in *Game of Thrones* to Tony Stark's ego, self-interest and hubris in the *Marvel Cinematic Universe*.

This notion of flawed leaders is not a new concept, being a core element of ancient Greek tragedies (as explored in, for example, Knox, 1998; Engle, 2008). Unfortunately, in recent times, we have had a tendency to forget such ancient insights thanks to the dominance of what Western (2019) terms *The Leader as Messiah*, with models such as transformational and authentic leadership, and the gushing profiles of leaders in business media, having the tendency to paint rosy pictures of great people with special talents that pay no attention to any darker, shadow sides.

Flawed leaders have received some attention in the realms of psychoanalysis and clinical psychology. Manfred Kets de Vries has spent decades analysing the darker side of leadership (e.g. in de Vries, & Miller, 1985; de Vries, & Balazs, 2010; de Vries, 2010). The awareness of derailers in one's psychological make-up plays a significant part of Ron Warren's 360-degree leadership personality model (Warren, 2017) as well as Anderson and Adams' (2016, 2019) mapping of creative competencies in opposition to self-limiting tendencies such as complying, protecting and coercive control.

Spiky leadership occurs when tragic flaws are overcome by a group of leaders undertaking mature teamwork that enables their collective intelligence (Wooley et al., 2010), capacities and talents cover for their weaknesses, biases and blind spots in an environment of psychological safety (Edmondson, 1999).

Utilizing the PLC framework to unpack this, at the inner capacity level, this will involve:

- A deep understanding of their drivers and derailers, or light and shadow sides.
- Awareness of their level of understanding of a subject or situation, and where their gaps and biases might lie, and the appropriate way they can contribute to further exploration.
- An understanding of their motivational styles, and the situations in which they will and will not be appropriate.

At the skilled adaptive capacity level, this will involve:

- An awareness of how many people their leadership decisions will impact and the degree to which they can or cannot frame and communicate those decisions in culturally and situationally appropriate and engaging ways.

- Understanding the degree to which they can or cannot frame complex challenges in a manner that enables comprehension, ideation and effectiveness in others.

- An awareness of how well they can or cannot drive results without sacrificing opportunities to explore and experiment with other potential methods and practices, or to appropriately reward contributors.

We feel that this concept of spikey leadership captures something essential about this emergent phenomenon captured in popular media of a more realistically human, complex and even deliberately developmental understanding of the need for collective leadership in facing complex adaptive challenges.

Assessment and Orientation

The usefulness of a framework to develop leadership raises the topics of assessment and the following questions: How can a person find their location within the framework? How can they use it to determine how to further their learning journey?

The framework is a real-world example of Piaget's (1970) concepts of epistemological and cognitive structures and of the hierarchical complexity of task accomplishment (Commons, Trudeau, Stein, Richards, & Krause, 1998). In other words, the framework serves as the mental structure, enabling and enabled by resources such as coaching, feedback, psychometrics or 360s, to navigate your leadership objectives and to navigate the steps of learning-cycle paths:

a) Orient oneself in terms of the skill levels and capacities across the framework.
b) Prioritize specific learning goals or development intentions.
c) Gain relevant information, explore and observe.
d) Experiment through practice in context.
e) Reflect on experience to connect new knowledge gained.
f) Iteratively reset goals and repeat the cycle.

This type of learning is exemplified by the learning cycle model of Dawson and Stein (2011a, b), where this action-reflection process generates micro adjustments enabling a robust and agile acquisition of the new level of capacity or skill.

Recommendations

Additional Research

In our design, we did include sources and feedback from the leadership traditions of social-justice, political and community development, as well as business anthropology traditions. However, we see potential in a more comprehensive exploration and integration with the PLC framework. For example, social activists' distinction between community organizing and community leading is something where we see common ground with the PLC, but different language. We are curious to learn if these are only language differences or if exploration would illuminate more substantial distinctions.

The discipline of *business anthropology* has been focused on technology and innovation and we would extend this lens to explore the subjects of leadership and leadership development more with the anthropologists' eye.

We also see the subject of humor as under-appreciated as a leadership capacity and a skill that can reduce tension, open relationships, create safety and is rooted in lateral thinking and consciousness of mindsets and culture.

There is room for a stronger integration of the disciplines around lean and agile practices and leadership. The business community wants more agility but often does not understand the technologists' practices and principles. The leadership development community wants to appeal to the business sponsors so they adopt, co-opt and corrupt the idea of agile, and the lean and agile communities have been overly focused on the processes and practices while working to formulate how leadership skills are important and what they are. Empirically, there are lean and agile contexts, but not something unique that is lean or agile leadership.

Finally, some research can focus on the further delineation and exploration of the detail topics that we frame as level 3. As more of this detail is exposed and organized, there will be constructs for pedagogical sequencing and more resources for practitioners.

Community Engagement

Once there is a published PLC framework, that framework has to be discovered, understood, welcomed and applied to be useful and to affect the change it is meant to support. An adequate strategy will require substantive relationships with all classes of associations, institutions, commercial and benevolent organizations. Engagement should be through relationships across stakeholders in the process of leading and developing leaders, as well as across disciplines. With regard to this, we have initiated a broader set of engagement programs.[15]

Reciprocal Sensitivity

The PLC framework is sensitive to the inevitable diversity of knowledge in the globalized world. We are respectful of contemporary ideas and the depth of work using theories and models that pre-existed today's discourse. Unrecognized differences, personal tendencies to fix positions, familiarity or past contexts cannot and should not be discounted, even if they seem challenging, clumsy or outdated. Consequently, the evolution of the framework must strike an elegant balance between useful theories of the past and multi-cultural sensitivities and new knowledge of the present. From this, it is our recommendation (and a principle of operation for us) that the framework is not meant to dominate or over-take other constructs but align with them and increase approachability for them across the whole of the range of stakeholders.

---

[15] For this we have opened a way to engage in stakeholders' collaboration through additional Prometheus Project initiatives of We Lead Global and The Clear Council, For more information please go to www.theprometheusproject.info

Governance

Deft choices of governance will be critical to establishing and attending to a common accessible leadership framework that serves its mission to open access and align quality across all stakeholders. The efficacy of the framework will be achieved as a collective ambition, and through collective influence. It has to be a part of the identity of a wide constituency. It cannot be dominated by one community, discipline, profession, economic class or culture.

We have an intention in our agency. We intend to establish a governance function that represents the best aspects of a purpose driven community, using collective intelligence, collective influence, and collective ambitions (*spikey leadership)* in the practices of framework innovation and the continued application of design-thinking principles and practices.

Cultural Assumptions

As in any substantive change initiative, there will be continuing attention to cultural adaptive change. These are a few of the changes that have more than a small immunity.

We have repeated experience speaking to executives who are impatient with program recommendations from mainstream leadership sources, yet they do not have an alternative frame of reference, advisors have investments in the status quo, executives hold personal immunities to changing accountabilities for leading. Many of those in the system are sustainers of the status quo.

Practitioners and experts are invested in their business and branding models, as well as in their identities and cultural assumptions around achievement, intellectual property rights, influence and dominance in the market.

The capabilities required to be an individual leader are idealized by both individual perfectionism and social norms.

The cultural component of leadership patriarchy is persistent and language is both a reflection and influencer of culture. Reserving the terms 'leadership' for the capacities of any role or position, 'executive' as the strategic authority of an organization and 'follower' as one of an array of choices *that leaders may take* would be progress.[16]

We assert that these and other, cultural assumptions are severely limiting as cause, not only evidence of effect.

---

[16] We find some vestiges of patriarchy is actually preserved in the popular distinction of leader vs follower. This is one of the reasons we explicitly included 'followership' as part of the engagement level 3 details. Leading includes situationally following, versus an alternative to following.

Conclusion

Speaking about the demands of leading in today's complex contexts, John S. Kem, (Major General, U.S. Army War College, who led the US Army officer leadership development programs) says it well; "the environment rewards clarity and punishes those who wait for certainty" (in the forward, Gavin & Watson, 2019, np).

This quote epitomizes the imperative for leading change in complexity. It is the imperative of our profession, not of our constituencies, to create clarity in the real world. Therefore, our priority must be to create and invite consent to a clear framework of the very capacities that we want to develop.

At the same time, even as the framework has immediate value, we expect to collectively learn as a stakeholder community. Naturally, some are disposed to wait for more or gather more. Reiche (2019) writes of the phenomena of the Fear of Better Options (FOBO) that applies to leadership, where consent and action are withheld in deference to diffusion of efforts or paralyzing detail. But often, there is sufficient knowledge consent for action and attention to learning.

To reach the point of our collective ambition, where leadership is understood, accessible, normalized and even *professionalized,*[17] then we must engage in adaptive work that is fueled from collective knowledge and collective influence.

This is why we are initiating two continuing structures, the engagement of a larger circle of stakeholders through We Lead Global, and the open, diverse, independent governance for framework, aptly named The Clear Council.[18]

We foresee a day when leadership development sponsors and practitioners readily find a flexible and cohesive field of resources, committed executives and self-determining learners at all levels of leading and effective organization and community-wide intentional development.

We invite you to join us on this adventure!

---

[17] Contributing to Kellerman's (2018) call for professionalizing leadership is part of the longer-term aspirations of The Prometheus Project.

[18] The Prometheus Project has a series of initiatives, including the Prometheus community forum of We Lead Global, The Prometheus Leadership Commons and its governance board, the Clear Council, and public events series related to all areas of The Prometheus Project mission. Stage Models of Adult Development: A Critical Introduction to Concepts, Debates, and Future Directions

Ben Bjorgaard[1]

Abstract: Diverse approaches have modeled and characterized a number of trajectories of adult psychological development that originate in stage models of developmental psychology. The number of these approaches has increased significantly in recent decades as stage models have become more popular and been applied outside of the academe, along with innovations occurring within the academe. Additionally, multiple stakeholders have sought knowledge about the types of thinking and psychological development suited for contemporary contexts and needed by individuals and communities to adequately respond to present and anticipated circumstances; this has gone hand-in-hand with psychological developmental models being increasingly applied across disciplines. The challenges involved in this research area have led to novel critical debates and developments. However, details about the theoretical and methodological foundations of these approaches are often underexamined, which can lead to misinterpretation and misapplication. This article sets out to survey some of these theoretical and methodological issues. Surveyed concepts and issues include functional, soft, and hard stages; metrics, models, constructs, and domains; and the relationship of stage models to the broader field of developmental science. Finally, suggestions about the study of adult development beyond stage models are provided including the need for interdisciplinary research and frameworks.

Keywords: Adult psychological development, applied developmental science, postconventional development, postformal development, problem-focused methodological pluralism, relational developmental systems.

Introduction

Many terms refer to trajectories and stages of psychological development that occur throughout adulthood. *Postformal* and *postconventional*, named in relation to Jean Piaget's (Inhelder & Piaget 1958) formal operational and Lawrence Kohlberg's (1984) conventional stages, may be the most common. Other suggested terms include, but are not limited to, *integrative*, *relativistic*, and *dialectical* (e.g., Kallio, 2011). Simply referring to these trajectories as adult development is another alternative. However, in most populations studied, individuals exhibiting characteristics of the most advanced stages are rarely found (e.g., Cook-Greuter, 2011); therefore, *exceptional* adult development can be a useful descriptor. Corresponding to these terms, a wide range of frameworks include a focus on adult development. This wide range lends itself – upon a close

examination – to overlap, isomorphism, synonymity, parallelism, as well as differences (both nuanced and radical), bifurcations, contentions, and misunderstandings. By and large, these adult development frameworks stem from a tradition of developmental psychology with a primary heuristic of stages going back to James Mark Baldwin (1895) and Piaget in the early 1900s with many approaches branching along the avenues paved by other historical and contemporary researchers (e.g., Basseches, 1984; Case, 1985; Erikson, 1982; Fischer, 1980; Gilligan, 1982; Kegan, 1982; Labouvie-Vief, 1982; Loevinger, 1976; O'Fallon, 2020; Pascual-Leone, 1970; Sinnott, 1998; Wade, 1996). Because a grasp of developmental stage models in general is needed to understand contemporary stage models of adult development, this article spans stage models at large while focusing on exceptional adult development; postformal and adult development are sometimes used as catch-all terms, although others are used when referring to specific frameworks.

This article presents a selective literature review in order to introduce concepts and distinctions relevant to evaluate and compare adult development frameworks – and particularly to provide an understanding of stage models that can support integrative and applied projects related to adult development. The study of adult development beckons integrative and synthetic frameworks from diverse fields. I set out to weave a condensed narrative that can introduce readers to important considerations of stage models and their context within developmental science. I use broad brushstrokes in an attempt to provide an overarching orientation to components of stage models of adult development and select examples in order to flesh out implications of how these components interact – although in many cases alternative examples could have been used. As a brief overview and introduction to a diverse territory, this article does not do justice to any particular model. It also omits concepts important to more detailed comparisons of some models, as well as alternative directions of future development. It is hoped that it provides a general orientation to debates and future directions of stage models of adult psychological development and their relevance to integrative developmental theory. It may be of most benefit to readers who have some familiarity with a developmental stage model.

An overarching conclusion is that continued work is needed addressing integrative visions of adult development that move beyond developmental psychology, and beyond stage models in particular – and that assessing how stage models of adult development function within broader cross-disciplinary integrations will be crucial to their future development. Due to the philosophy of science, methodologies, and evidentiary basis undergirding stage models of adult development, cross-disciplinary comparisons can be vital for their evaluation and interpretation. Relatedly, these considerations can help to hone their pragmatic and ecological validity – how developmental constructs fair when applied in open systems in the real world, and how stage models can and should be used.

First, Cook-Greuter's (1999) expansion of Jane Loevinger's (1976) model, a widely used framework of adult development, is briefly summarized as a case study in order to contextualize and provide a foil with which to compare further distinctions, in addition to introducing contemporary trends. Next, distinctions between functional, soft, and hard stage models are introduced, followed by debates about metrics, models, constructs, and domains. Then, an underdiscussed relationship of stage models of adult development to a recent paradigm shift (termed Relational Developmental Systems) in the broader field of developmental science is considered. Last, a discussion about what these findings regarding stage models mean for broader, potentially transdisciplinary, approaches to adult development is provided, including suggestions about future directions. Interested readers can see Gidley (2016) for a wide-ranging overview and comparison of descriptive characterizations of postformal models.

Loevinger and Cook-Greuter

In her doctoral dissertation, Cook-Greuter (1999) built on Loevinger's (1976) Ego Development Theory and measuring instrument, The Washington University Sentence Completion Test (WUSCT) to research hypothesized further stages of postconventional development. Cook-Greuter accomplished this goal by comparing postconventional development categories in Loevinger's model to a number of other developmental theories. This project was motivated by rare outlier WUSCT results from previous studies that could not be meaningfully interpreted within Loevinger's model. In addition, Cook-Greuter tested her new conceptualization of stages by analyzing 145 postconventional WUSCTs to refine theoretical categories and 60 WUSCT protocols to assess for statistical validity and reliability.

An ego stage according to Loevinger's theory can be described as a particular cohesive view of reality – of self, external circumstances, and existential situation – that is part and parcel of one's sense-making (Cook-Greuter, 1999). Development is posited to occur through hierarchically complex and differentiated stages as an individual matures, as it is conceptualized in most stage theories. The WUSCT tests for ego stage by asking an individual to freely complete sentence stems (usually 36), which are then assessed by a researcher using a manual that categorizes elements of language corresponding with the various stages. According to Cook-Greuter, the WUSCT was thoroughly tested for reliability and validity at the time of its development; it has also continued to be tested and critiqued (Manners & Durkin, 2001).

In 2011, Pfaffenberger, Marko, and Combs published an edited volume that focused on Cook-Greuter's work and legacy, *The Postconventional Personality*. In this volume, Cook-Greuter (2011) described several developments that occurred since the publication of her dissertation. The WUSCT database continued to grow, which led to further nuanced findings that were important in refining the measurements of postconventional stages, since protocols scoring at these stages are rare. Protocols scoring at stage 10 (the highest stage) were found in an average of only .06% of sample populations. Cook-Greuter reflected on the relationship between a growing database and the models and methods used to assess it:

> The question is whether and to what degree to tailor the psychometrics to best reflect the findings or whether to *honor* a method now seemingly suboptimal in light of the data. How to do this in a valid psychometric fashion without employing Bayes' theorem is the challenge. As a developmental measure, based on empirical evidence, the SCT requires new theory and new measurement approaches when the data changes. Another pertinent and practical question is at what point in time does one introduce radical changes to an established measure including new metrics and recalculate, readjust older samples in light of the new evidence? (p. 61)

This quotation describes the interdependent relationship between research, theoretical models, and metrics, in addition to touching on several points that are discussed in greater detail below. Cook-

Greuter further stated that Loevinger's measure continued to be applied in new contexts, including longitudinally and across cultures. Several doctoral dissertations tested and applied Cook-Greuter's post-conventional stages (e.g., Boyer, 2005; Hewlett, 2004). Cook-Greuter (2011) considered additional differentiated stages and recently hypothesized a new substage (Ego-aware) that would help to explain certain discontinuities between the highest stages she originally proposed. New sentence stems and their scoring manuals were introduced in order to better fit contemporary contexts. Cook-Greuter developed a training program for scoring the tests and utilizing developmental perspectives for researchers and "coaches, consultants, and change agents" (p. 67). Cook-Greuter also discussed how Ken Wilber's (2000) integral theory and the integral community helped to popularize her work, and how this moved her away from research and toward applications in professional development. Relatedly, the WUSCT was increasingly adapted for applied versus research settings. Last, Cook-Greuter discussed how the WUSCT's growing popularity in applied settings had in turn led to a greater demand for trained individuals capable of scoring tests in the post-conventional stages and differentiating between new patterns in test results from high achievers knowledgeable about developmental theories versus the genuine stages indicated by them.

The foundations and developments Cook-Greuter (1999, 2011) described in many ways parallel those of other approaches to adult development. To summarize, Loevinger (1976) developed a theory of development rooted in the psychoanalytic theories of Henry Stack Sullivan (1968) and Erik Erikson (1982), and then refined several constructs of that theory, which remarkably could be validated and tested for using a relatively simple test that takes about a half hour to complete. Similarly, Cook-Greuter called upon additional theories that seemed to imply further stages of adult development, and continued to refine ego development theory and its operationalization through the WUSCT. Loevinger's and Cook-Greuter's process is representative of approaches to stage models of adult development in that particular theories of development rooted in broader psychological models, revolving around a certain aspect and construct of a given approach, are validated and tested through traditional psychometric methods, statistical analyses, and instruments.

The qualifications and grains of salt that go along with these processes, and powerful but limited methods, are often left in the background. However, these models have led to a variety of useful ways to conceptualize, research, and apply adult development. These include different takes on domains (what develops) and stages (with what structure), as well as how and why development occurs. They also include similarities and isomorphisms that lend themselves to the common practice of creating a diagram that aligns alternative models' conceptualizations of stages with one's own. This is commonly used to support the coherence and theoretical development of a given model; however, there is also a danger of conflation – the variety of viewpoints contained leads to a challenge of appropriately considering the gamut of theoretical and methodological variables in a synthetical or organizational project. The image of a kaleidoscope with shifting, interacting shapes and angles surfacing as one gazes at adult development goes some way to describe the state of the field and the difficulty of interpreting what one actually sees.

Functional, Soft, and Hard Stages

Many of the continued debates within the field of adult development relate to general debates and theoretical distinctions pertinent to the field of developmental psychology at large. They have been ongoing since the foundations of the developmental field and are best understood within that context. For example, Lerner's (2018) overview of the history of developmental theory included an explication of distinctions between continuous versus discontinuous change, nomothetic versus idiographic models, and elementarism versus holism. Lerner stated,

> The point of these examples is that, despite a relatively high degree of consensus about development being a theoretical concept that, at the least, connotes systematic and successive change in an organization, there is a good deal of disagreement among developmental scientists about what particular ideas need to be added in order to define the term adequately. These differences in definitions are associated with philosophical and theoretical differences which also divide scientists. (p. 11)

Although it is outside the scope of this article, a thorough comparison of approaches to postformal development would necessarily call upon these foundational distinctions and an examination of how they are employed in other areas of developmental psychology. For instance, stage models are largely nomothetic, generalizable across individuals, and omit idiographic considerations unique to each individual's development; however, this distinction also plays out differently within various stage models, and there are possible routes of synthesis as will be outlined below.

Perhaps the most foundational distinctions between postformal approaches are those between functional, soft, and hard stage models. Reams (2014) outlined four criteria attributed to Piaget that are used to make these distinctions: (a) stage models display a qualitative difference in the structures of stages, (b) stages develop in an invariant sequence, (c) there is an underlying organizational structure of the stages as a whole, and (d) later stages include and integrate previous stages while also displaying progressive differentiation of their contents. Functional stage models meet the fewest of these criteria, hard stage models meet all, and soft stage models fall in between. Erik Erikson's (1982) widely known model is an example of a functional model in that it is culturally relative, organized around responses to common life experiences particular to a society, and not structurally hierarchical in a strict sense (Reams, 2014). Functional stage models may be relevant and valuable to a specific community, but lack evidence supporting them as a veritable model of universal developmental structures.

Loevinger (1976) and Cook-Greuter's (1999) models, on the other hand, are examples of soft stage models. Their structures are derived hypothetically from the measurement of a construct inferred from categories of content on the WUSCT. Those categories are mixtures of content and structure thought to indicate a stable set of personality and ego functions. In this way, Loevinger's stages are "ideal type[s] based on [a] theoretical representation" (Reams, 2014, p. 129). While they have structural qualities, such as qualitatively different hierarchical organizations that meet much of the above criteria, they fall short of hard stage models in the following ways: The method and evidence by which the model is arrived at are more indirect and speculative; stages are defined by functions of a holistic self and its motives, as well as by linguistic content, rather than strict structures. This leeway enables soft stage models to formulate their characteristic broad, far-reaching theories, for instance, constructs that delimit universal patterns of meaning-making, yet may also tend to lose the trees in the forest, not be as rigorously defensible as harder stage models, or prove with further research to be as coherent and cohesive as their theories claim.

Hard stage models involve the delimitation of structures within discrete domains (Reams, 2014). For instance, in contrast to an ego developmental model, hard stage models would examine the specific acquired skills that the self experiences as unified (e.g., physical, emotional, and cognitive tasks) that relate to “empirically observable and measurable actions in direct ways” (p. 129), and by doing so, according to Reams, perhaps articulate more defensible, and universal, developmental logics that would continue to be applicable with the advancement of psychological knowledge. Lourenço (2016) offered a similar characterization of hard and soft stages of development and further qualifies that hard structural stages are

> necessary rather than optional tracks of development…, embody operative reasoning which represents interiorized and reversible forms of action…, distinguish content from the form or structure of thought…, can be formalized within a rational, normative model…, [and] appeal to an epistemic, or rational, general subject as opposed to a psychological, individual subject. (p. 124)

It is notable that characterizations of postformal development tend to blossom from soft stage models. The greater flexibility of soft stage models may serve in formulations of exceptional adult development. Postformal stages tend to highlight reflexivity; awareness of constructs; relativity; and a grasping of multiple points of view, systems, and paradigms. Perhaps structures explanatory of these functions are challenging to operationalize within the strict criteria of hard stage models. Along these lines, Stein (2008) suggested that developmental evaluations can be considered as “rational reconstructions of a kind of deep-seated intuitive knowledge that is *always already* a part of the network of practices and beliefs that constitute the lifeworld” (p. 3). In other words, there may be a tacit knowledge and “groking” of developmental trajectories, at least those of thought and language, at large in human interactions that are brought to consciousness in various ways by different developmental models and evaluations. Stein conducted an exploratory study to research this hypothesis by asking 181 non-specialist participants to rate the developmental levels of interview transcripts. In support of the hypothesis, Stein found general agreement between raters with each other, as well as between raters and the Lectical Assessment System’s formalized metric of development. Soft stages’ more speculative and holistic models may allow a greater operationalization of this intuition. However, particularly in soft models developing outside of academia, there are challenges in formulating defensible academic knowledge. There have also been major strides in hard stage approaches to postformal development in recent decades. These developments have led to current debates on properly differentiating and utilizing models, metrics, and constructs.

Models, Metrics, and Constructs

What does it really mean when an individual scores at Cook-Greuter’s (1999) Autonomous stage on the WUSCT, or at another stage on an alternative developmental system? How should those scores be interpreted? What are the standards and quality control procedures of developmental systems? Ross (2008) traced how information about developmental systems can become increasingly distorted when that information is distanced from the academic research contexts where it originates. For instance, qualifications of developmental systems that are implicitly obvious to researchers – who are trained in the specific psychometrics used to arrive at them – can be lost as that research is consumed, reinterpreted, and communicated by others. Ross used the metaphor of telephone games and outlined the particular example of how figures in Wilber's (2006) *Integral Spirituality* promulgated distortions and errors both in the discourse of academics specializing in other areas and especially outside of the academe.

Psychometric models, metrics, and measures are the lifeblood of postformal developmental systems and commonly underlie the misinterpretation of those systems (Stein & Heikkinen, 2009). Stein and Heikkinen set out to demystify these facets of psychometrics in order to offer a quality control framework. This framework is particularly valuable for users of developmental stage models who do not specialize in them. In addition, Stein and Heikkinen provided a "limited, exploratory" review assessing metrics currently in use by various developmental approaches, and found a "conspicuous lack of psychometric rigor on the part of some developmental approaches" (p. 5). Supporting the keystone quality of metrics, Stein and Heikkinen outlined that in developmental psychology, metrics are calibrated via psychometrics (in contrast to measuring methodologies of other fields such as biometrics or sociometrics). These metrics inform the discipline's discourse about models, which in turn inform applied technologies, such as testing in education.

Metrics and models can both be considered the development discipline's representational devices: symbol systems, methods, and propositions claimed to refer to actual developmental processes (Stein & Heikkinen, 2009). Metrics are used to determine the quantity or degree of a psychological attribute that is found in a set of performances. Metrics can take the form of calibrated measures or soft measures (not to be confused with soft stages). Calibrated measures rely more-so on quantitative protocols in their development, whereas soft measures rely more-so on qualitative protocols. Models account for and characterize – explain and describe – the presence of psychological attributes. Furthermore, Stein and Heikkinen distinguished different quality control devices for metrics and models. Metrics are controlled via psychometric tests of validity (reasonableness of inferences and claims) and reliability (quality of performance and error proneness). Models are controlled via disciplinary discourse, a community's critical interchange of arguments and evidence, both theoretical – targeting the "truth, coherence, and reasonableness of models" – and practical – targeting their "ethics, efficacy, and implications" (p. 7).

In developmental psychology, metrics are essentially "inter-subjectively codified modes of systematic differential classification" (Stein & Heikkinen, 2009, p. 10) that are proclaimed to be indexes of development. The degree and type of calibration a metric has undergone determines its status as a soft or calibrated measure. Stein and Heikkinen pointed out that the history of cognitive developmental research has been "a history of techniques for the classification of various performances and behaviors" (p. 11). Additionally, although there are some outliers such as Piagetian balance beam tasks, nearly all developmental metrics interpret linguistic performances. However, the modes and analyses of linguistic performances can vary subtly and substantially. For instance, Kohlberg's (1984) moral stage model relied on analyzing the content of interviews, Loevinger's (1976) model relied on the analysis of projected sentence completions, and other metrics such as hierarchical complexity (discussed below) analyze deep structures of linguistic performances rather than their content. Stein and Heikkinen summarized the general procedure used to develop a metric:

> the codification of a metric begins with a research team issuing relatively informal judgments about how the various performances in a dataset should be organized developmentally. That is, they argue about why one performance is more developed than another, suggesting various properties of the performances that should function as indexes of development. Then through iterative procedures for garnering intersubjective agreement, an explicit hierarchical taxonomy emerges and specific properties of the linguistic performances are promoted to the status of being indexes of development. That is, developmental metrics are built to function as *representational devices*; they are created to help us *see* development by privileging specific properties of linguistic performances that have proven useful for the purpose of reliable differential developmental classification. (p. 11)

When codification results predominantly from researchers iteratively surveying large longitudinal data sets until reaching an intersubjective agreement about their "inventory of level-specific conceptual content" (p. 12), it is a soft measure. Calibrated measures go through further quantitative analysis to refine the metric and ensure the validity and reliability of fine-grained individual distinctions. The soft/calibrated categories are relative to a degree. Metrics can be more specifically described in relation to the variety of types of validity and reliability, the claims of the model they correspond to, and the context in which they are used. Additionally, soft measures can become calibrated, and calibrated can become soft, depending on the quantitative evidence available at a given time. However, in general, metrics that are noisy (vary from rater to rater) within a reasonable range of error are soft measures. These differences can make soft measures unsuitable for applied settings, especially when purporting to draw conclusions about individuals. However, they are suitable for research purposes, especially when searching for patterns across sample populations. On the contrary, calibrated measures are more suited for applied settings and making distinctions at the individual level in addition to research. For instance, although Loevinger's metric was better calibrated than many soft measures, Stein and Heikkinen claimed that Loevinger explicitly stated "it was *not* [Stein and Heikkinen's emphasis] to be used for rendering measurements of individuals" (p. 9). Stein and Heikkinen also found that the Hierarchical Complexity Scoring System and Lectical Assessment System were the only truly calibrated metrics at the time, "using quantitative indexes of internal consistency" (p. 19).

As for the quality control of models, Stein and Heikkinen (2009) proposed that multiple frameworks of evaluation can be useful in determining a model's value. As an example, they suggested Charles Sanders Peirce's (1998) distinctions between *utility*, *security*, and *uberty*. Utility refers to a model's fitness as a means to an end. Security refers to what types of evidence a model is based on and how coherent is the model and this evidence. Uberty refers to the magnitude of a model's "world-disclosing power" (p. 14) and suggestiveness. A model may, for instance, have a low security value, lacking evidence, but a high uberty value, being comprehensive and shining a light on a variety of disparate situations. Thus, distinctions between soft and calibrated metrics (as well as soft, hard, and functional stages) do not imply value judgments in themselves, and should not motivate a homogenization or marginalization of metric and model types. Furthermore, Stein and Heikkinen suggested an "integral and problem focused metrological pluralism" (p. 20), a pragmatic ideal involving reflections on developmental metrics and their uses, including detailed validity and reliability profiles, to inform decisions about which metrics are suited for which purposes. This ideal can also be extended to other aspects of developmental approaches.

Soft, hard, and functional stages interact intimately with soft and calibrated metrics (e.g. functional stage models tending to use no metrics, soft models tending to use soft metrics, and hard models tending to use calibrated metrics), as well as with further distinctions outside of the scope of this article, resulting in advantages and disadvantages, including potential misapplication (e.g., soft measures inaccurately assessing individuals in applied settings, such as at work or school, and leading to negative outcomes for those individuals). In this way, there are a host of qualifications that should be brought to light about any developmental approach before it is put to use, perhaps the most important being qualifications about its metric and the metric's relationship to its model.

Additionally, there is a further layer that can be brought into the discussion of metrics and models: addressing construct validity theory itself. The categories of content, structure, and performance attributed to stages in developmental models are notably abstract constructs, especially those of later adult developmental stages. While metrics are designed to measure psychological attributes, they do so through constructs. For instance, Slaney (2017) stated, "Loevinger contended that while traits exist in people, constructs 'exist in the minds and magazines of psychologists…*Construct* connotes construction and artifice'" (p. 3). Therefore, more accurately stated, metrics measure the amount of a construct reflected in test performances assumed to refer to actual attributes based on limited statistical evidence. Some of these statistical limitations are further discussed in a following section. Statistical methods and criteria related to construct validity have continued to develop since their formulation. Current arguments go as far as to question the validity of the overarching paradigm of these statistical methods in certain contexts, particularly their relationship to environmental validity and applications in developmental psychology (Diehl, Wahl, & Freund, 2017; Lerner & Callina, 2013).

Of course, it is precisely the function of testing theories and studying hypothesized attributes with characteristics that are to a large extent unknown that necessitates the use of constructs. However, the potential conflation with their referents; the false ontology attributed to constructs (and thereby metrics, models, and whole approaches to development); the lack of qualifying their limitations, including their openness to further tests of validation and invalidation; and a potential blending of confirmatory and exploratory objectives and implicit circular reasoning (Slaney, 2017), can lead to an additional false security of developmental approaches. Furthermore, the reliance on psychometrics and relatively brief linguistic performances limit the developmental stage approach as a whole. In light of these considerations, it may be worth musing on how the oft-quoted Bronfenbrenner (1979) statement referring to methodological limitations in developmental psychology might apply to developmental stage approaches: "developmental psychology…is the science of strange behavior of children in strange situations with strange adults for the briefest possible periods of time" (Bronfenbrenner, 1979, p. 19).

Domains

Perhaps the most discussed distinction within developmental stage discourse is between domain general and specific models. Domains refer to the particular area that stages apply to. Do stages apply to the total structure of an individual's psychology, to specific skills and capacities, or is the structure of development somehow separate from any content, being able to be applied to any domain, general or specific? Are there primary domains necessary to develop before others? Are there particular domains that interact in patterned ways, following a more or less universal path across a lifespan? Or is the concept of domain itself simplistic, obscuring the complex, contingent, ever-shifting, individual webs of skills and capacities interdependent with one's environment that one can perceive more generally or specifically within different contexts, frameworks, and objectives? These are some of the questions scholarly discourse has examined. As it may be clear, conceptions of domains are interdependent with other aspects of developmental structures. Because of this, a brief account of stages themselves is called for.

As mentioned, that development occurs in discontinuous stages or through continuous change has been a dichotomy motivating reoccurring debate throughout the history of developmental psychology. Some continue to question the relevancy of stages (e.g., Truhon, 2012); others argue that there cannot be a developmental psychology without some concept of stages, whether going by stages or another term, such as "periods, levels, phases, cycles, seasons, [or] layers" (Lourenço, 2016, p. 126). Lourenço explicated several additional questions relevant to this controversy: Do stages exist? Where are they? What features define a sequence of developmental stages? What factors and processes underlie change, be it either continuous or discontinuous? Dawson-Tunik, Fischer, and Stein (2004) argued that stages should not be at the center of developmental theory, even of stage theories, nor did Piaget intend them to be. On the contrary, the psychological processes of equilibration and reflective abstraction were the centerpiece of Piaget's theory, and stages are a heuristic tool to aid the description and understanding of behavior developing from these and similar processes.

These are potentially muddy waters with different avenues for seeking clarity. Different domains and their conceptualizations can align to different sets and numbers of stages; relatedly, different domains can highlight different conceptions of change and stability, process and stage. Additionally, approaches focused more on content or structure attempt to integrate one another, with structural models being more apt and likely to do so. It is a diverse and shifting kaleidoscope indeed. For instance, Dawson-Tunik, Commons, Wilson, and Fischer (2005) pointed out that research has supported both continuous and discontinuous models of development and variations of them, and that development can appear continuous or discontinuous depending on the conditions.

To further research the contested "shape of development" using a domain-general approach – specifically Dawson-Tunik's Lectical Assessment System, which is based upon Commons' Model of Hierarchical Complexity (Commons, Trudeau, Stein, Richards, & Krause, 1998) and Fischer's Skill Theory (Fischer, 1980) – Dawson-Tunik, Commons, Wilson, and Fischer (2005) analyzed 747 moral judgement interviews for broad changes in conceptual development. A domain-general approach uses criteria that are independent of particular content and can therefore be used across domains of specific content (Dawson, Xie, & Wilson, 2003). Dawson-Tunik's system, Commons' model, and Fischer's theory have developed somewhat in parallel, spearheading contemporary versions of the domain-general approach. Dawson-Tunik et al. (2005) suggested that while most researchers acknowledge that different domains may develop at different rates, and different processes and structures may correspond to different domains, there may still be a more general developmental process and structure that applies across domains, which they termed *hierarchical integration* and/or *complexity*. They concluded that their results suggest "development [across the lifespan] proceeds in a series of spurts and plateaus across six complexity levels" (pp. 26-27). This, in addition to other examples of their research comparing the Hierarchical Complexity Scoring System with other domains and metrics further supports their domain-general approach (e.g., Dawson, 2001, 2002). Dawson-Tunik et al. (2005) provided the caveat that while hierarchical complexity explains a great deal about a performance (e.g., its form and order of abstraction), it makes no claim about explaining its content. Rather, its content must be assessed independently and then integrated with information about hierarchical complexity. It should be noted that this broad-brushed survey, in its attempt to introduce a variety of ways to conceptualize domains, is liable to leave a number of details unpacked that are vital for assessing an individual approach; for instance, important distinctions between the Lectical Assessment System, Fischer's Skill Theory, the Model of Hierarchical Complexity, and the Hierarchical Complexity Scoring System (e.g., see Commons, 2009). These details would require digging into a particular model and its supporting research.

It may be helpful to distinguish between general or specific domains (referring to the breadth of their content) and domain-general or specific approaches (referring to whether the developmental approach as a whole applies only to a particular content). For instance, Loevinger's (1976) model is general at a content level, encompassing the totality of a personality, while not addressing specific, individual skills. On the other hand, the Model of Hierarchical Complexity can be applied to any content domain, broad or specific. However, it does not necessarily imply a more general content domain. For instance, Mascolo (2008) stated that

> Individuals do not operate "at a stage of development." They operate at a range of different levels of hierarchical complexity depending on skill area, task, context, degree of support, and other variables. It is thus necessary to postulate the concept of *domain* to refer to the particular conceptual, behavioral, or affective area within which activity operates. (p. 330)

Yet, the Model of Hierarchical Complexity can also apply to general content domains. Wolfsont, Ross, Miller, Commons, and Chernoff (2008) described how it can account for the evolution of general intelligence:

> the evolution of humans required performing increasingly hierarchically complex tasks within multiple domains. Hierarchical complexity increases task by task. Tasks occur within, and differ by, determinable domains, their stages of performance measurable using the Model of Hierarchical Complexity. How well one performs within single and multiple domains is considered to indicate intelligence. (p. 416)

Murray (2009) questioned whether the Lectical Assessment System and Hierarchical Complexity can really apply across domains as coherently as their theorists suggest. Are certain metrics, even certain paradigms informing the development of assessments, limited to certain types of domains? Murray took what can be considered a softer stage approach and argued that some formal models, particularly ones that are cognitively-and-linguistically-oriented may be limited to a "cognitive line," which he partially characterized as the information processing and logical-rational functions of thought. Further, he suggested that these models might overlook an umbrella of "wisdom skills," functions he characterized as letting go, emptying, opening, un-learning, as well as "ego awareness, construct awareness, socio-emotional-relational skills, dialectical intelligence, negative capability, empathy, and compassion" (p. 353). He also suggested that perhaps the term *cognitive line* is more-so a term used to contrast with the host of functions overlooked by some formal models, and that other models such as Loevinger's (1976) might encompass some of these left-out wisdom skills.

Heikkinen (2009) countered Murray's argument. Heikkinen suggested that while many important changes in "body/mind/soul" (p. 369) such as Murray described, and other important human trajectories, may occur according to different logics than underlie a model like hierarchical complexity, arguing that those changes are equivalent to development rests upon one's definition of development and more-so on the evidence for that definition; otherwise, any sort of change could potentially be confused with development. Trickier still is operationalizing and measuring a concept of development to further test it, for instance, to differentiate it from confounding variables and assessing the validity and reliability of such a concept. When done so, alternative concepts of development may in fact be found to not follow a developmental pathway, or they might be found to be attributed to another underlying developmental logic, such as hierarchical complexity. Heikkinen argued that Murray's fundamental questions are empirical. She then provided an example of how hierarchical complexity could be controlled for in studies to differentiate it from ego development theory, or Kegan's (1982) constructive-developmental model, to explain how much of the variance of scores are explained by hierarchical complexity versus other systems, and to effectively see whether those alternative systems tap into hierarchical complexity or other truly different aspects of development.

To conclude this section, it is hoped that this brief overview of perspectives about domains has provided a sketch of their relationship with other aspects of developmental approaches, some contemporary avenues of debate and research, and the stakes of conceptualizing and operationalizing domains in the overall meaning of a developmental approach. Furthermore, it is hoped that the overarching review of functional, soft, and hard stages; and models, metrics, constructs, and domains, has been evocative of the complexity of interpreting and applying developmental stage models – to arrive more at open questions and possibilities of interpretation rather than a set of fixed conclusions.

Relational Developmental Systems

To open further beyond stage models: The stage model tradition of developmental psychology is a relatively distinct branch. This distinctness is emphasized by the particularity of constructs, models, and metrics of specific approaches. Once a specific model is formulated it can become an isolated tradition in and of itself, revolving around its own constructs and metric. While there has been continued refinement of methods and theories particular to stage traditions, there has been a paradigm shift within the broader field of developmental psychology that few stage models have grappled with.

Nearing the turn of the millennium the term *developmental psychology* began to be eclipsed by the term *developmental science* (Bronfenbrennar & Evans, 2000), including the renaming of journals and handbooks tied to the field. This rebranding went along with a heightened interdisciplinary focus, as well as reflection and debate about the fundamental assumptions, paradigms, theories, and methods of the field, which finally resulted in what has widely been heralded as a paradigm shift termed the Relational Developmental Systems Paradigm (Lerner, Overton, & Molenaar, 2015). This paradigm is characterized only very briefly and partially here. It is predicated upon a process-relational philosophical perspective thought to transcend Cartesian dualism, atomism, and positivist reductionism. It rejects "all splits between components of the ecology of human development (e.g., between nature- and nurture-based variables, between continuity and discontinuity, and between stability and instability)" (p. xviii.). It replaces these dichotomies with holistic syntheses using an "integration of three relational moments of analysis: the identity of opposites, the opposites of identity, and the syntheses of wholes" (p. xviii), which can have a profound impact on the methodology and interpretation of research traditions – in part by processually integrating dichotomies that the field of developmental psychology has struggled with at large. It emphasizes that "all levels of organization with the ecology of human development are integrated or fused" (p. xviii), that basic units of analysis are individual-context relations and co-actions of these, and that organisms are "inherently active, self-creating, self-organizing, and self-regulating nonlinear complex adaptive systems," which develop through embodied activities (p. xviii). Development is inherently context-sensitive, plastic, subject-specific, and stochastic (probabilistic or random) (p. 3). Interested readers can see Overton (2015) for a succinct overview of the Relational Developmental Systems Paradigm and its corresponding metatheory, and Dick and Müller (2017) for further exploration of the Relational Developmental Systems Paradigm and its application in different areas of developmental science.

Describing the paradigm in depth and unpacking the particular implications of this paradigm shift for stage models of adult development is largely outside of the scope of this paper due to its complexity and the number of possibilities of stepping down the paradigm into specific theories and approaches. While unpacking the implications of the paradigm for stage models of psychological development is needed – should stages explicitly be conceptualized as abstracted, partial moments embedded into a vision of an integrated, processual whole? – each individual stage model might also grapple with this paradigm in unique ways. However, the implication of the Relational Developmental Systems Paradigm for the integration of basic and applied research should be noted:

> in contemporary developmental science any splits between basic and applied research are regarded as anachronistic representations of the reductionist, Cartesian approaches of earlier eras. In short, the application of developmental science (optimization) is a co-equal partner with description and explanation within developmental science as it now exists. (Lerner, Overton, & Molenaar, 2015, pp. xvii-xviii)

The more distanced basic research and theorizing about stage models are from ecologically valid, applied contexts, the more suspect.

Furthermore, human development – the subject of developmental science – is now thought to be predominantly nonergodic. Ergodicity describes mathematical and statistical qualities of systems that must apply for standard statistical analyses to be accurate: “In developmental research, almost all functions of natural development and intervention processes are nonergodic. Therefore, standard statistical analysis of aggregate-level data is bound to result in descriptions of developmental structures that fail to describe the individual” (Lerner, Overton, & Molenaar, 2015, p. 803). This has led to a surge of methodological innovation and borrowing, as well as critique focused on the fundamental limitations and errors of traditional statistical methods applied in developmental psychology (Little, Gorrall, Panko, & Curtis, 2017). Two specific emphases are on the individual as a unit of analysis and the ecological validity of experimental designs (Diehl, Wahl, & Freund, 2017; Nesselroade, 2017). The outcomes of this paradigm shift have yet to reverberate throughout the kaleidoscopes of stage models and conceptions of postformal development, and that their evidence, methods, and models may look profoundly different in coming years. The Relational Developmental Systems Paradigm can also provide a new context from which to qualify, interpret, and apply stage models of development – and to scaffold the integration of stage models of adult development with other domains of developmental science and allied projects from other fields.

Discussion and Conclusions

Adult development can be seen through the kaleidoscope of diverse models and metrics, as well as their triangulations. It can be approached in versions of hard, soft, and functional stages; soft and calibrated metrics; and general and specific domains. While arguments can be made that certain stage models measure aspects of bona fide psychological development, we have seen that delimiting processes of development and its measurement within stage model discourse also requires contextualization, debate, and interpretation. Relatedly, the relative insularity of stage model discourse can tend to reify notions of adult development, as constructed within stage model discourse, as more comprehensive or substantive than they would appear with a more open and cross-disciplinary discourse about adult development. Different approaches and models have different uses, which an analysis of their components can help to identify. Many of these qualifications also apply to approaches to adult development stemming from other branches of psychology and other disciplines – although potentially requiring alternative criteria for making evaluations. Notably, many diverse models closer to or within the realm of psychotherapy can be thought to include their own theories of adult development (e.g., Maslow, 1971; Rogers, 1961; Jung, 1964). Furthermore, literatures within fields such as wisdom research, spirituality, self-development, health and wellness, contemplative studies, education, leadership, and epistemology, among many others, contain threads that closely relate to adult development. These examples are primarily intended to evoke the potential for more integrative models of adult development, and secondarily for more pragmatic, contextual models to suit certain purposes – that knowledge provided by stage models can be used to inform customized, integrative conceptualizations of adult development, which paradigms like Relational Developmental Systems can help to support. Stein’s (2008) notion of how developmental evaluations relate to “rational reconstructions of a kind of deep-seated intuitive knowledge” (p. 3) can again be applicable here. The potential to abductively infer conceptualizations of adult development best suited to a given context could be promoted via broader integrative frameworks and specialized customizations.

From this broader perspective, stage models of adult development can largely be characterized, as Stein and Heikkinen (2009) suggested, as the branch of adult development that specializes in psychometrics and construct validation. We have overviewed some of the methods and forms of evidence this entails. Of particular relevance here is Murray's (2009) and Heikkinen's (2009) debate regarding forms of development that stage models might leave out – or from the alternative view, perhaps should leave out. Furthermore, constructs such as learning, growth, self-actualization, individuation, change, wisdom, and transformation overlap closely with development. However, are there underlying logics, processes, and structures that are more defensible to claim as bona fide development? Are methods of construct validation, and even psychometrics at large, the best ways to certify that bona fide development? While there continue to be strides in psychometric methodology, there have also been challenges to some of its core assumptions. Walking the tightrope that these questions entail requires applying broader frameworks of assessment, akin to those Stein and Heikkinen (2009) suggested. This might include making criteria of hard stage models explicit in each case. It might also include applying metatheoretical distinctions such as Charles Sanders Peirce's (1998) utility, security, and uberty, or those from Relational Developmental Systems, or an alternative to the overarching scope of stage models itself.

Yet, from other disciplinary perspectives and paradigms, the assessment of security, utility, and uberty can shift. This includes when other methods and forms of evidence are incorporated into current stage models. It was suggested how the Relational Developmental Systems Paradigm may serve the integration of these points of view within developmental science. Other paradigms and disciplinary approaches may be relevant as well. With so many perspectives currently available, further work on adult development will likely entail comparing, integrating, and evaluating theories at a metatheoretical level (e.g., Edwards, 2010; Wallis, 2016); as well as the development of applied interdisciplinary specialists and frameworks of assessment (e.g., Bammer, 2013; Hvidtfeldt, 2018).

An important related consideration is that as scholars attempt to describe some overarching characterization of adult development at more abstract, synthetic orders, they can quickly enter the realm of philosophy and speculation – with its own set of strengths and limitations. Much of the work on adult development at this time is motivated by a search to grasp the types of thinking, and ways of being, needed for our particularly complex world and its related crises. The philosophizing that attempts to characterize this mode of thought is both inherent to many of the models and constructs in the study of adult development, as well as separate speculative work inspired by it. Basseches (2009) discussed the relationship between philosophical argument, systematic measurement, and forms of empirical data in these endeavors. He suggested that no "amount or form of empirical data can substitute for philosophical argument" (p. 312), and that the study of development is inherently philosophical. For example, he stated "Piaget's contribution was to offer observations of ontogenesis as a novel way of addressing existing epistemological questions, ontogenetic data were used in the service of philosophical argument and demonstration, rather than offered as a substitute" (312). Philosophical approaches are essential and inevitable; appropriately delimiting them and their relationship to empirical data are vital to their success.

This predicament – having multiple disciplinary and interdisciplinary approaches and paradigms relevant to the study of adult development, a need to understand the modes of thought most useful in contemporary contexts, and a need to evaluate these projects – emphasizes both the continued need for more typically hard science advances (for instance, generalizable measurement), and softer, functional, philosophical advances related to synthesis and contextual application – and greater coordination between the two. One side of this is bound to be greater incorporation of mainstream advances in developmental science. Another is likely to include applied problem-focused methodological pluralism, action research, and equivalent endeavors. One example along these lines is developmental maieutics (Dawson & Stein, 2011), which operationalizes a stage model of development in cycles of research and practice to produce usable knowledge in the context of educational assessment and in crafting effective learning sequences. Another is Collaborative Developmental Action Inquiry (Torbert, 2013), which although referring to a meta-paradigm of social science and social action, can in part be understood to operationalize stage models of development in the context of organizational change.

There are many paths forward for the study of adult development. This article primarily overviewed concepts necessary to evaluate stage models in general; thereby making suggestions about their continued refinement. Secondary functions of the overview were to set up a comparison to other paradigms – both in and outside of the developmental science discipline – and to emphasize a need for metatheory, metascience, and interdisciplinarity in the study of adult development. Hand-in-hand with this was an emphasis on problem-focused methodological pluralism – as humans are increasingly understood as embodied, context-ridden, becomings-in-process, many signs point to a need for interactive, ecologically-embedded, applied methods to develop an effective understanding of development, and to appropriately apply that understanding. As the popular interest in stage models of adult development is likely to continue, as well as their translation to academic and public discourses further afield, it is particularly important to delimit and qualify them – including the potential unknowns involved in the current most validated models.

Being Prepared to be Unprepared: Meaning Making is Critical for the Resilience of Critical Infrastructure Systems

John E. Thomas, Thomas P. Seager, Thomas J. Murray, Scott Cloutier[1]

Abstract: Infrastructure is essential to provision of public health, safety, and well-being. Yet, even critical infrastructure systems cannot be designed, constructed, and operated to be robust to the myriad of surprising hazards they are likely to be subject to. As such, there has been increasing emphasis in Federal policy on enhancing infrastructure *resilience*. Nonetheless, existing research on infrastructure systems often overlooks the role of individual decision-making and team dynamics under the conditions of high

ambiguity and uncertainty typically associated with surprise. Although evidence suggests that human factors correlating with resilience and adaptive capacity emerge in later stages of psychological development, there is an acute need for new knowledge about the human capacity to comprehend increasing levels of complexity in the context of rapidly evolving technological, ecological, and social stress conditions. Sometimes, it is this developmental capacity for meaning-making that is the difference between adaptive and maladaptive response. Thus, without a better understanding of the human capacity to develop and assign meaning to complex systems, unquestioned misconceptions about the human role may prevail. In this work, we examine the dynamic relationships between human and technological systems from a developmental perspective. We argue that knowledge of resilient human development can improve system resilience by aligning roles and responsibilities with the developmental capacities of individuals and groups responsible for the design, operation, and management of critical infrastructures. Taking a holistic approach that draws on both psychology and resilience engineering literature facilitates construction of an integrated model that lends itself to empirical verification of future research.

Keywords: Human development, human resilience, infrastructure, resilience, resilience engineering.

Introduction

National policies and guidelines for critical infrastructure resilience effectively acknowledge the complex, multi-organizational, and sociotechnical integration of people and technical systems (DHS, 2013; The White House, 2013). These policies support the concept of critical infrastructure resilience as a function of coupled social and technical systems' physical and functional characteristics (Madni & Jackson, 2009), which includes the dynamic relationships between systems (Hollnagel, Woods, & Leveson, 2006). The physical and functional characteristics are often considered in a context of spatial and temporal dimensions. These are standard dimensions for analysis using traditional systems theory and other deterministic methods well suited for technological systems. For example, the factors related to spatial and temporal dimensions of a power system failure can impact assessments of community resilience (Munzberg, Wiens, & Schultmann, 2016) in response to disruption. However, the incorporation of human systems requires an additional dimension of symbolic meaning be included (Holling & Gunderson, 2002) together with space and time. In an analysis of the scholarly literature comparing the theme of resilience in social psychology, ecology, planning, and engineering disciplines, Fleming (2016) found that engineering scholarship focused predominantly on the "highly technical" side of "natural systems," and tends to ignore social systems. Though perhaps not surprising, this is problematic.

The meaning-making dimension accounts for the dynamic properties of complex adaptive human systems embedded within technological systems and operating environments proximal to physical infrastructure. That is, the human capacity to assign meaning and to dynamically interpret events and information relevant to critical infrastructure operation and management in response to disruption can impact the resilience of human coupled infrastructure systems. While many systems are designed to limit or minimize the role of human interaction, human ingenuity may sometimes be relevant to successful adaptation. Therefore, without a better understanding of the human capacity to construct meaning, reductionist views of resilience and tacit assumptions about the complex roles of humans interacting with infrastructure will prevail.

For example, disasters such as the Three Mile Island accident in 1979, the Challenger explosion in 1986, and the New Orleans Levee breakdowns in 2005 illustrate how the complexity of human interactions with technology can amplify failures in coupled systems (Perrow, 2011). By contrast, events like the ditching of US Airways Flight 1549 in the Hudson River on 15 January 2009 (NTSB, 2010) and the safe return of Apollo 13 in 1970 (Madni & Jackson, 2009) demonstrate how human ingenuity and adaptation can overcome surprising technological system breakdowns. Each situation required unanticipated changes in operational complexity and performance and although these examples are extreme, other similar scenarios play out across multiple domains and scales that go unnoticed by the public or academia. In a worst case scenario, unexpected and unknown changes can lead to catastrophic system failures propagating across spatial and temporal dimensions and operating domains such as the Fukushima power plant disaster in 2011 (Park, Seager, & Rao, 2011). In each case, the people involved make decisions and take actions based on mental models – psychological renderings of perceived or imagined conditions (Olson, Arvai, & Thorp, 2011) – that may no longer be relevant when subject to surprise. This means mental models can fail when faced with unanticipated emergent phenomena requiring an adaptive response to ambiguity and uncertainty (Sweet et al., 2014). Therefore, disasters can create conflict between preconceived conditions and direct experience (Hollnagel, Paries, Woods, & Wreathall, 2011) that can impact human interactions with technological systems.

The unanticipated differences between actual and preconceived experience of a person in a disaster scenario may be incompatible with their designated roles and responsibilities corresponding to thoughts, actions, and behaviors. As such, effective adaptation can require dynamic adjustment of individual roles to accommodate unknown or unexpected conditions. In the examples above, human lives were dependent on the ability of the pilots, crew, operators, engineers, and others interacting with the relevant technical systems to comprehend the situation and adjust to maintain viable system performance levels. Responding to adversity with incompatible preconceived responses can amplify failures and make conditions worse (Hollnagel & Fujita, 2013; Hollnagel et al., 2011), which means the roles played by humans can be pivotal to critical infrastructure resilience. In other words, human ingenuity can either enhance or diminish resilience because the intentions, motivations, and judgments of a single individual can influence infrastructure meta-systemic (whole-system) dynamics and outcomes. Moreover, while it may seem apparent why “preparing a large population for any kind of disaster will require a developmental perspective on human resilience, risk, and vulnerability” (Masten & Obradovic, 2010, p-11) the dichotomy of possible roles played by humans in disaster scenarios highlights this important point.

From a resilience engineering perspective, resilient outcomes are a factor of the recursive processes describing the capacities of intentional systems – sensing, anticipating, adapting, and learning (Park, Seager, Rao, Convertino, & Linkov, 2013). Thus, the resilience processes involved with navigating actual versus preconceived experience are partly determined by the complex interactional dynamics between humans and technical systems striving to restore and maintain viable operating levels. Dynamic adjustments to roles and responsibilities can require reinterpreting existing information while giving rational meaning to new and sometimes conflicting information in response to unanticipated or previously inconceivable events (Hollnagel et al., 2011). With potential near-term outcomes ranging from widespread environmental contamination to loss of life, the cascading impacts of disasters can have long lasting social and economic consequences that are less apparent (Cardona, 2003). For example, the human ability to adapt to climate change is a long time scale event with broad impacts linking complex relationships reflecting values, ethics, and world views (Adger et al., 2009) with human development (O'Brien & Hochachka, 2010) and built infrastructure.

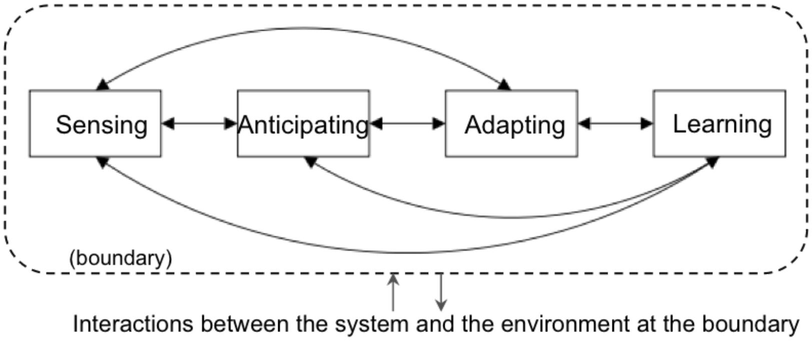
Although humans behave like complex adaptive systems, resilience research linking the dynamic interactions between humans and infrastructure is limited (Seager et al., 2017). As a result, it is difficult to communicate complex resilience concepts and collaborate across disciplinary boundaries like psychology and engineering. Moreover, the meanings and interpretations of knowledge, operational dynamics, and events influence human perspectives of system performance, which can vary across people and cultures involved. Other factors include the context of certain roles and responsibilities for a given scenario and corresponding environmental conditions. Thus, in addition to the epistemological perspectives representing multiple ways of knowing coupled systems across relevant spatial and temporal dimensions, critical infrastructure resilience must integrate epistemological diversity to form a holistic perspective reflecting how different human systems comprehend and interact with technological systems. This approach requires understanding how humans assign meaning and interpret knowledge, which includes experience in relation to infrastructure resilience operations and management and how the processes can change across time.

Human psychological development contributes to a body of knowledge and understanding about how people make meaning of the world and interpret experience. Disaster events identify knowledge gaps between the relationships of human resilience, development, and the ability of people to respond and recover (Masten & Obradovic, 2010), which is dependent on critical infrastructure. Although human agency influences behaviors, actions, and interactions with other systems (Brown & Westaway, 2011; Nelson, Adger, & Brown, 2007), there is little research integrating resilience and adult human development perspectives with the resilience of critical infrastructure operations and management. Although less is known about how resilience appears in adults given a significant research focus on youth (Campbell-Sills, Cohan, & Stein, 2006), progress in adult human development research has advanced and offers new insights about adult resilience. A growing body of research describes how human development endures well into adulthood and throughout a lifespan (Cook-Greuter, 2004; Kegan, 2002; Kohlberg, 1973; Loevinger, 1976; Vincent, Ward, & Denson, 2015).

In this paper, we address a gap in the resilience engineering and infrastructure resilience literature to consider how the psychological meaning-making of humans interacting with infrastructure operations and management can influence factors related to perceptions and interpretations of resilience. To accomplish this, we apply a holistic approach that allows for simultaneous perspectives drawing on the resilience engineering, psychology, and human development literature. We review multiple frameworks, synthesize diverse concepts, and propose a conceptual model for investigating the relationships between the developmental capacity of meaning-making and critical infrastructure resilience. The model effectively integrates the socio-technical resilience processes – sensing, anticipating, adapting, and learning – with human developmental capacities. Our analysis suggests that each stage of human development brings new psychological resources contributing to the capacity to comprehend and respond to increasing levels of complexity and uncertainty thereby enhancing the effectiveness of the socio-technical resilience processes. We contribute a conceptual model as a guide for future research. We argue that progressive stages of human development corresponding to more complex forms of meaning-making bring new qualities and capabilities for designers, operators, and managers that can strengthen and enhance critical infrastructure resilience.

A Holistic Perspective of Resilience Engineering Processes

A holistic approach incorporates epistemological diversity to understand the complexity and uncertainty of maintaining a viable operating performance level for critical infrastructure (Thomas, Eisenberg, & Seager, 2018). Whereas a focus on anticipating known failures related to operational disruptions and human interactions with infrastructure can enhance risks mitigation efforts (Cardona et al., 2012), preparing to be unprepared may require circumventing deterministic preparations and responses (Park et al., 2013). Moreover, the adaptive capacities of people, organizations, and engineered systems are interdependent on an ability to accommodate unknown *internal* and *external* changes (Hollnagel et al., 2011). In other words, adaptation to unpredictable system shocks may sometimes require abandoning prescriptive actions while dynamically constructing novel solutions. With regard to human systems, interactions and feedback loops maintain a sense of (rational) equilibrium by forming psychological structures that either filter incoming data to fit existing worldviews or creating new worldviews (John Manners & Durkin, 2000). Thus, a holistic framework of critical infrastructure resilience must integrate the endogenous human factors corresponding to the adaptive capacity of people and working groups interacting (proximal) with technology in addition to sensing, anticipating and learning (Thomas et al., 2018). Without consideration of human dynamics and developmental predispositions, which includes how people interpret and make meaning of information and events, even seemingly comprehensive analyzes of coupled social and technical systems risk offering partial solutions by ignoring critical dependencies.



Sensing

Interactions between the system and the environment at the boundary

Figure 1. Sociotechnical resilience processes – sensing, anticipating, adapting, and learning (SAAL).[2]

---

[2] The feedback loops represent the recursive and reciprocal relationships between processes. The boundary condition represented by the dashed line defines the physical and functional areas of consideration for a given scenario. The resilience processes interact with the proximal environment at the boundary (Seager et al., 2017; Thomas, Eisenberg, Seager, & Fisher, 2019).

The 'SAAL' processes (Figure 1) describe four abilities of resilient systems: sensing, anticipating, adapting, and learning (Hollnagel, 2014; Park et al., 2013). Sensing is the ability to detect system state variables; anticipating is the ability imagine changes in system conditions and state variables; adapting is the ability to adjust system performance while maintaining viable operation; learning is the ability to absorb, retain, and access knowledge from experience. The processes represent the recursive and reciprocal relationships between complex socio-technical systems that influence resilience. Taken together, the SAAL processes provide a coupling mechanism for linking dynamic interactions between humans and critical infrastructure (Park et al., 2013). For example, in addition to planning and preparation, humans are integral to the management and operational response to disasters and catastrophic events (Madni & Jackson, 2009). Moreover, officials and civil servants as individuals, teams, and organizations must coordinate and maintain critical infrastructure technical mitigation and recovery (and adaptation) policies and resources (Labaka, Hernantes, & Sarriegi, 2016) while also providing a diversity of rescue (recovery) and support services across other systems, (e.g. public health and safety). The four abilities are a way to describe the resilience of the coupled human–infrastructure system. Thus, the SAAL processes provide a means for describing the dynamic relationships between people and infrastructure (Thomas et al., 2019). In addition to adaptive behaviors, the relationships can also include maladaptive behaviors (Masten & Obradovic, 2010), as observed with events like Hurricane Katrina (Westrum, 2005).

The catastrophic consequences of Hurricane Katrina revealed numerous latent human inadequacies during the recovery efforts, including physical deficiencies, personnel failures, organizational failures, and bureaucracy failures (Westrum, 2005). Multiple breakdowns across operational domains exposed a myriad of individual and organizational deficits including poor leadership, poor judgment, and criminal behavior of officials. Over 200 civil servants either deserted or were absent without official leave including 25 police officers who quit while on duty at areas of intense stress and two officers who committed suicide (Westrum, 2005). "It seemed as if no one was in control. In a very real sense this was true" (Westrum, 2005, p. 5). In other words, there was a catastrophic breakdown in the human component of recovery management in multiple overlapping operating domains within the city of New Orleans. Beginning with a profound lack of preparation cited just a year earlier (Laska, 2008), a "social catastrophe" ensued (Cutter & Emrich, 2006) along with a complete loss of power, loss of the levees system, loss of communications, and a loss of civil obedience among numerous officials (Westrum, 2005). A capstone to the emergency management breakdowns in New Orleans in response to hurricane Katrina, the mayor of New Orleans when the hurricane hit in 2005 was sentenced to federal prison in 2014 (Murphy & Peristein, 2014) for corruption and gaff during and after the hurricane struck the city.

In contrast to the diminished moral capacity prevalent among a cross section of civil servants, there were also examples of exceptional human performance during Hurricane Katrina. Admiral Thad Allen, the commander of the U.S. Coast Guard gained high regard for his leadership during the recovery efforts (Sullenberger & Century, 2012). His rapid response was unscripted and credited with saving thousands of people. Allen was appointed Director of the Federal Emergency Management Agency at a time of organizational dysfunction. His ability to articulate and enact a set shared values among staff, was recognized as exceptional leadership in a most difficult of circumstances.

Moral development is relevant to critical infrastructure resilience engineering for two reasons. First, moral maturity is related to human resilience (Kumpfer, 1995), which means it is embedded in any consideration of infrastructure resilience that includes people. Second, because an individual's capacity for moral reasoning may be viewed as a protective factor for people (Stokols, Lejano, & Hipp, 2013), moral development is interrelated to the dynamic interactions between and among humans, technical systems, and environments.

Given the complex, interdependent, and interconnected nature of infrastructure systems, certain critical roles (e.g., managers and operators) require individuals to make sense of systems in complex ways that can involve high degrees of ambiguity and uncertainty. Evidence from research in developmental psychology suggest that human factors such as interpersonal awareness, the capacity to consider alternative perspectives, complex systems thinking, and adaptive capacities emerge and advance in later stages of human development (Cook-Greuter, 2004; Vincent, 2015). Moreover, research by Cook-Greuter (1999) supports the notion that capacities for complex systems thinking are rare human traits only accessible after passing through a sequence of developmental stages. Other evidence suggest that individuals are often discouraged from developing by existing educational institutions and management structures (Torbert et al., 2004). Furthermore, Cook-Greuter's data (n=4,510) indicates that fewer than 20% of the adult population arrive at the later (postconventional) stages of development (Cook-Greuter, 1999). As a result, certain catastrophic infrastructure breakdowns may exceed the capacity of some individuals to effectively function and cope with high degrees of complexity and uncertainty. The developmental stages support a holistic structure for linking diverse concepts of resilience involving human interactions with – operating and managing – infrastructure. Thus, in addition to the potential to enhance anticipation of potential threats and outcomes, a key benefit of a holistic framework integrating human development and critical infrastructure resilience processes is to align operations and management roles and responsibilities with individual strengths and adaptive capacities of people.

Human Development Theoretical Framework and Potential Implications for Infrastructure Resilience

Human development theory incorporates epistemological diversity to account for differences in how people make meaning and interpret knowledge in different contexts across time. That is, the way in which individuals experience resilience concepts and how those concepts and definitions influence relationships and proposed solutions over time correspond to the human capacity to develop more complex ways of interpreting and interacting with their environment. In this section, we examine different human development theories to identify one able to support a holistic framework for critical infrastructure management applications.

Early Developmental Theories

Jean Piaget (1954) is considered to have developed the first structural model of cognitive development (called "genetic epistemology"). He created a comprehensive empirical method to assess the capacity for rational thought and describe how patterns or stages of cognition emerge in developing children and adolescents. Piaget identified the important transition from "concrete" to "formal" cognitive capacities that allow for abstract concepts, logical reasoning, and the rigorous imagination of possibilities/alternatives.

Building on Piaget's work Lawrence Kohlberg developed a theory of moral development describing six types of moral reasoning in children and adults (Kohlberg, 1969, 1973). The six stages appear amongst three tiers – pre-conventional, conventional, and post-conventional (Kohlberg, 1969, 1973). A related pattern was found by William Perry's in his study of "epistemological growth," or how people relate to knowledge and belief – its sources, justifications, and evolution in people and society (Perry, 1970). Pre-conventional stages are not much concerned with either moral principles or how beliefs are justified. Conventional stages look to authorities and peer groups for both valid knowledge and moral rules. Post-conventional individuals have well developed "formal operations" that allow them to think autonomously and critically about both knowledge and ethical principles.

As noted with Hurricane Katrina, moral development is relevant to critical infrastructure resilience engineering partly because an individual's capacity for moral reasoning may be viewed as a *protective factor* for people (Stokols et al., 2013) impacting human resilience and decision making. In other words, moral development may influence the dynamic interactions between and among humans and technical systems. Epistemological sophistication is also relevant to critical infrastructure resilience because in unexpected scenarios the normative procedures may not apply, and critical thinking, reevaluation, and creative problem solving are needed. Importantly, research shows that under stress cognitive capacities can deregulate, which can be viewed as a developmental "down shifting" to earlier levels of complexity capacity (Goleman, 2006; LeDoux, 1996).

Development of Cognitive Complexity

It is now a cliché and truism that we live in a "complex and fast-changing world." Increasingly we understand that real-world situations are "ill-defined" or "wicked," characterized by "vague or broad goals; large volumes of data from many sources; nonlinear, often uncharted analytical paths; no pre-set entry or stopping points; many contending legitimate options; collaborators with different priorities; [and] 'good enough' solutions with no one right answer (Mirel, 2004). Robert Kegan (1994, p. 12) notes that "when we experience the world as 'too complex' we are not just experiencing the complexity of the world. We are experiencing a mismatch between the world's complexity and our own at this moment. There are only two logical ways to mend this mismatch – reduce the world's complexity or increase our own. The first isn't going to happen." This concept links the developmental complexity of the infrastructure managers to the operational complexity of the infrastructure systems.

Developmental stage theories provide a way to understand the relationships between coupled human – infrastructure systems. As described by Gardner (1983), people exhibit "multiple intelligences" – a framework extended by Wilber who articulated over a dozen developmental "lines" studied by researchers (Wilber, 2000). Although researchers differ on the mechanisms, stratification schemes, and definitions of developmental levels, there is a surprising degree of correspondence among dozens of theories as to the general outlines of adult cognitive development. Domains studied include cognitive development (Piaget, 1954; Murray, Hufnagel, Gruber, Vonèche, & Voneche, 1979), moral development (Gilligan, 1982; Kohlberg, 1969), ego development (Cook-Greuter, 2004; Loevinger, 1966, 1976) values development (Beck & Cowan, 2006; Graves, 1970), epistemic development (Perry, 1970), and socio-emotional development (Goleman, 2006). So-called neo-Piagetian theories have also emerged proposing underlying mechanisms involved in all forms of development (Commons & Richards, 1984; Fischer, 1980).

In practice the sub-skills underlying many of these "lines" have common roots and overlapping branches, and we can focus on two broad categories of cognitive development. The first is *cognitive complexity* (using the narrow definition of cognitive as intellectual skill distinct from social/emotional skill); and the second is *meaning-making* capacity, which is Kegan's term for a skill-set that substantially overlaps with Loevinger's construct of ego development (we treat the two as essentially equivalent).

Cognitive complexity refers to the complexity of mental operations applied to some task or problem. More complexity involves more parts, relationships, factors, dynamism, interdependence, and/or unpredictability (Benbya & McKelvey, 2006; Grünwald & Vitányi, 2003). Elliott Jaques, who studied the complexity of tasks, jobs, and cognition, states that “the true source of difficulty in any problem lies in its complexity” (1996, p. 64). Jaques applied his findings to management and organizational theory, finding that “complexity may be defined in terms of the number of variables that have to be dealt with in a given time in a situation, the clarity and precision with which they can be identified, and their rate of change" (ibid). He developed methods for matching task and job complexity to an individual's cognitive complexity. Coming to conclusions compatible with those of Commons, Jaques identified two fundamental elements of cognitive complexity (Jaques, 1989). First, understanding in an area develops from simply recognizing or defining things and working with one variable at a time ("declarative"), to understanding simple relationships among them ("cumulative"), to understanding more complex relational and cause/effect chains ("serial"), to inter-related co-causal relationships and whole systems that coordinate multiple relational chains ("parallel"). Second, this entire sequence of increasing complexity happens first for semi-concrete (and symbolic) information, and then it reiterates for abstract systems of information.

Our increasingly complex world requires increasingly complex cognition to understand it – and *humans* and human systems are among the most complex objects we must think about. Meaning-making capacity can be understood as the application of cognitive complexity to domains involving human emotions, interiors, groups, and knowledge. Intellectual skills by themselves are understood to apply to the domain of "it" or external objects, but these skills can be applied to, not *some* idea, but *my/your/our/their* ideas (or needs, values, etc.).

Loevinger and Wessler (1970) say that "conceptual complexity has proven to be an important clue to [stage of ego development]" (v. I, p. 115); and Kegan's model describes how underlying "cognitive, interpersonal, and interpersonal" structures ("lines") develop in parallel. These theories were developed to understand how the average person understands "the world," including self and other, but since our context includes the technical and engineering domains involved in infrastructure resilience, we need to clarify that the complexity we will focus on is “meaning-making” complexity, which includes intellectual (strictly cognitive) complexity, but only to the degree needed to understand "the world" at a given level of sophistication. It seems self-evident that one can have a high degree of complex intellectual knowledge about a system yet not have the ego development or meaning-making sophistication to, for example: question whether one is over-confident in one's knowledge, seek alternative perspectives, or flexibly adapt one's knowledge when it is proven inadequate. Strictly cognitive skills are important for routine (even advanced) engineering, design, and problem solving work, but in social-technical situations involving rapid change, multiple perspectives, or unpredictability, meaning-making skills are critical.

Constructive Developmental Theories

Researchers including Robert Kegan (1980, 1982) and Jane Loevinger (1979, 1983; 1970) created theories of "meaning making" (called "ego development" by Loevinger) that incorporate all of the above mentioned modalities – cognitive, epistemological, and ethical (including social/emotional) reasoning – into a single construct and framework. These theories are *holistic* – integrating cognitive, affective, and behavioral elements. Furthermore, these three core dimensions align with prior work relating human and technical resilience capacities through the SAAL socio-technical processes (Thomas et al., 2019).

A central tenet of these "constructive-developmental" theories is that people construct and interpret meaning and identity in an ongoing manner to understand and adapt to changing life conditions and experiences. The developmental perspective shifts the focus on human understanding from *behavior* and *what* people think to *how* people think – i.e. to underlying cognitive structures that influence how complex problems are perceived and approached and how solutions are proposed and justified (Cook-Greuter, 1999; Kegan, 2002).

The gradual accumulation of new interpretations and ways of making meaning constructs an invariant sequence of psychological structures identified as levels or stages of development representing increasingly complex, nuanced, and creative ways of interpreting and navigating life conditions and experiences (Cook-Greuter, 1999; Kegan, 1982; Kohlberg, 1969; Loevinger, 1983). Each level brings new capacities while strengthening and building on existing capacities. As the complexity and uncertainty of life conditions and environments increases, developing individuals are challenged to build more comprehensive psychological meaning-making systems (Cook-Greuter, 2004) and an increasing capacity for positive adaptation (Hauser, 1999).

Meaning making (or ego) development spans a spectrum from black-and-white, narcissistic, impulsive, us-vs-them, short-sighted, and simplistic thinking into increasingly complex, nuanced, flexible, adaptive, reflective, expansive, empathic, and pro-social thinking. Vincent notes that as meaning-making develops "each shift in stage offers greater cognitive complexity, a more integrated perspective, greater self and interpersonal awareness, responsibility and personal autonomy, decreasing defensiveness and increasing flexibility, reflection and skill in interacting with the environment" (2015, p. 3). Here the reader can recognize the close connection between the research in developmental science and the need for adaptive and resilient approaches to socio-technical systems.

A developmental perspective on human resilience offers a better understanding of what type of adaptive responses may be possible when critical infrastructure resilience includes human factors. Because developmental theories outline specific levels and detailed skill progressions, questions of resilience capability can be translated from vague notions or binary categories (is or is not resilient) into a more detailed and discriminating framework composed of multiple levels that have already been researched. A consideration of human development may assist, for example, with aligning management roles and responsibilities of people holding critical positions in emergency response networks. It can also help managers assess matches of tasks and situation complexity to human capacity in any situation, and especially in changing or uncertain contexts.

The Ego Development Theories of Loevinger & Cook-Greuter

Though Kegan's and Loevinger's theories cover very similar territory, we will focus on Loevinger's ego development theory (though "meaning making" development may still be a more apt term) because (1) it has been more used and validated, and (2) its assessment method, the sentence completion test (SCT) is more practical and also more strongly validated.

The literature drawing on Loevinger's ego development model is so extensive that it includes a number of meta-analysis and critical overviews, substantially supporting its validity and usefulness (Cohn & Westenberg, 2004; Holt, 1980; Jespersen, Kroger, & Martinussen, 2013; Manners & Durkin, 2001; Novy & Francis, 1992; Vincent, Ward, & Denson, 2013). According to an overview by Cohn & Westenberg (2004) the SCT has very strong psychometric properties, having "indicated excellent reliability, construct validity, and clinical utility" (p. 596). As of their 2004 article, "findings of over 350 empirical studies generally support critical assumptions underlying the ego development construct" (p. 485). Blumentritt (2011, p. 153) says that "more than 1,000 articles and book chapters have been published examining nearly every conceivable aspect of the construct and measurement of ego development [showing an overall] substantial support" for the theory and measurement.

Translated into over ten languages (Cohn & Westenberg, 2004), the SCT has been used to study personality differences (Westenberg & Block, 1993), leadership (B. C. Brown, 2011; Vincent et al., 2013), management and organizational development (Torbert et al., 2004), and individual resilience (Gralinski-Bakker, Hauser, Stott, Billings, & Allen, 2004; Hauser, 1999). Pfaffenberger (2011, p. 10) says that "the face validity of the SCT is demonstrated by the sheer fact that it has been used in more than 300 research studies [including] such diverse topics as parenting behaviors, managerial effectiveness, and the effects of meditation on recidivism rates." Numerous studies have shown that ego development is distinct from but correlated with general intelligence (about a 30% correlation) and verbal fluency, and, as expected, like IQ, it correlates with socioeconomic status (Cohn & Westenberg, 2004; Crammer, 1999; Manners & Durkin, 2001). Pfaffenberger (2011, p. 10) says "the SCT correlates with education, socioeconomic status, and complexity of work, which has been shown to hold true across international samples" (emphasis added).

Cook-Greuter’s research enhanced and extended the seminal work of Jane Loevinger at the postconventional levels (Cook-Greuter, 1999). Cook-Greuter’s research showed that the ‘Strategist’ stage or structure in Loevinger’s model appears as two distinct stage structures. Data collected from 4,510 participants over a period of 15 years were used to characterize an additional post-conventional level and to verify adjustments to the SCT measurement instrument

(Cook-Greuter, 1999). Table 1 identifies the "action logics" system of meaning making, and central focus for each stage along with the distribution of stages among research subjects. The dashed lines identify the stages most relevant to the present research and are discussed in more detail in the next section. The research also provided new details about the post-conventional stages such as an enhanced capacity to cope with complexity and uncertainty and an improved ability to adapt to change (Cook-Greuter, 1999; John Manners & Durkin, 2000; Vincent et al., 2015). These considerations can have both causal and prognostic implications for the resilience of infrastructure systems within which human systems are embedded.

Table 1. Ego-development Stages, Action Logics, and Central Focus.[3]

Stage Name	**Action Logic**	**Central Focus**	**% Adults** (N=4,510)
Preconventional			
Opportunist	Needs rule impulses	Own immediate needs, opportunities, self-protection	4.3
Conventional			
Diplomat	Norms rule needs	Socially expected behavior, approval	11.3
Expert	Craft logic rules norms	Expertise, procedure and efficiency	36.5
Achiever	System effectiveness rules craft logic	Delivery of results, effectiveness, goals, success within a system	29.7
Post-conventional			
Individualist	Relativism rules single-system logic	Self in relation to system, interaction to system	11.3
Strategists	Most valuable principles rule relativism	Linking theory and principles with practice, dynamic systems interactions	4.9
Alchemist	Deep processes and inter-systemic evolution rules principles	Interplay of awareness, thought, action, and effects; transforming self and others.	2.0

Cook-Greuter's framework was extended further by O'Fallon in her STAGES model (Murray, 2017; O'Fallon, 2011). STAGES formalizes and extends Cook-Greuter's original notion of a sequence of "person-perspectives" into a sequence of six person-perspective transformations (i.e. first, second, third...sixth person-perspective). It proposes an underlying set of generative parameters that give rise to the entire developmental sequence, including growth from concrete to increasingly abstract (or "subtle") objects of awareness, advancing cognition from individual objects to collectives and systems of objects, and moving from receptive to more active and reciprocal orientations to knowledge. O'Fallon's SCT scoring method is much less dependent on the content of the sentence completions (i.e. is more focused on underlying structure) and thus her method is more extensible to new domains.

---

[3] Stage names by Cook-Greuter (and Torbert); Action Logics are meaning-making systems with increasing complexity; Central Focus describes a psycho-social disposition or frame of reference dominant for each stage; % Adults are the results of a 15 year study involving 4,510 adults across a broad range of demographics. (Cook-Greuter, 2004; Torbert et al., 2004).

Both the theoretical model and the assessment method described above apply to critical infrastructures whereby roles and responsibilities are impacted by the resilient development of the designers, operators, and managers involved as noted earlier with the contrasting management responses to Hurricane Katrina. That is, psychological meaning-making structures supporting the different ways of interpreting events, experiences, and changes associated with stages of development can impact how people interact with and influence the resilience of complex technological systems like infrastructure.

Ego Development Applied to Infrastructure Resilience Management

Studies Linking Human Resilience and Development

Related studies of human development focus on how children and young adults learn and grow (develop) in different support-and-challenge contexts. These studies offer valuable insight to human development by emphasizing a behavioral perspective of the interactions of individuals exposed to different environments such as risk and adversity (Masten, 2001), social ecology and diversity (Bronfenbrenner, 1999; Ungar, Ghazinour, & Richter, 2013), and cultural tensions (Ungar, 2006). In general these studies show that supportive social networks enhance an individual's resilience, and that resilient personalities withstand stressful situations more favorably (Masten & Obradovic, 2008). Within the Loevinger lineage we can note two longitudinal studies relating human development and resilience.

In the first study, data gathered at the beginning and end of a nine-year period showed a strong positive relationship between measurements of ego-resiliency and ego-development (Westenberg & Block, 1993). Empirical evidence suggests that ego resiliency and ego-development are interrelated, and that development may occur at different rates among individuals within the same age group (Westenberg & Block, 1993). Ego-resiliency, which describes “flexible and resourceful adaptation” was divided into three subdomains, and each proved interrelated to ego development. Although the relationship between ego-resiliency and ego-development did not contrast or change among ego stage transitions, a strong, coherent relationship was apparent. Another important finding relevant to our paper is the anticipated and observed strong positive relation between interpersonal integrity and ego development. Interpersonal integrity, which describes a capacity for authentic relations, was subdivided into two subdomains, and each revealed a strong, coherent relationship with ego-development.

Although the age range of the participants does not represent middle-aged managers, this study is most relevant to the work herein because it provides evidence of the interrelatedness between concepts of human resilience and human development. The data suggest that the properties that correlate with the resilience of a person also correlate with patterns of ego development. A potential application to infrastructure resilience is the alignment of short and long-term roles and responsibilities with consideration of individual human strengths and growth opportunities.

In the second study, multiple sets of data collected over a 20 year period found associations between ego-development and a set of themes characterizing a group of people demonstrating resilient outcomes in young adult life despite extreme adversity in childhood (Gralinski-Bakker et al., 2004; Hauser, 1999). The research posits a perspective of resilience as the positive adaptation in response to adversity (Masten, Best, & Garmezy, 1990) and includes measurements and assessments of both internal states of being *and* observed actions and outcomes (Gralinski-Bakker et al., 2004; Hauser, 1999). The research findings are relevant to our integration of human resilience and development with critical resilience for two reasons.

First, whereas the research described above reviewed data collected at the end points of a nine-year period, this longitudinal study collected data over a period of 20 years, in addition to the endpoints, including adolescence and young adulthood. Although single cross-sectional or time-point assessments can yield valuable insights, longitudinal research is vital to understanding potential trajectories of resilient development in humans (Gralinski-Bakker et al., 2004; Hauser, 1999), technical systems (Igor Linkov et al., 2013; Park et al., 2013), and social systems (Brown & Westaway, 2011; Walker, Holling, Carpenter, & Kinzig, 2004).

The second reason this study is relevant to the present work is the comprehensive research approach, tools, and methods used. The instruments, which included Loevinger's ego development test, provided reliable and repeatable measurements of the protective factors, which were later used as predictors of outcomes (Gralinski-Bakker et al., 2004) in the third phase of data collection. The factors characterize a perspective of resilience as an *internal* state of being and positive adaptation to adverse events and changing life and environmental conditions (Hauser, 1999). In other words, the research included both endogenous and exogenous measures and assessments of resilient human development. The rigor of data collection, analysis, and published findings of Hauser's research supports our conceptual framework for integrating a perspective of resilient human development with critical infrastructure resilience.

Ego-Development Stages Influence on the SAAL processes

Although ego stages may be viewed as coherent personality structures, Loevinger considered ego as a reference frame or a "lens" influencing an individuals' perceptions of the world (Cohn & Westenberg, 2004). Whereas "the depth, complexity, and scope of what people notice can expand throughout life," (Cook-Greuter, 2004, p4), protective factors like resilience and adaptive capacity are particularly enhanced in *later* stages of development (Gralinski-Bakker et al., 2004; Hauser, 1999; Westenberg & Block, 1993).

We emphasize the four stages in Table 2 as a focus of our human development framework for two reasons. First, the distribution of stages in Cook-Greuter's data suggests that over 80% of the sample represent a stage at or below the conventional tier. Other researchers report similar findings whereby the majority of the adult population appear to reside at either the expert or achiever stages (Manners & Durkin, 2000; Vincent, 2015). We have excluded the Opportunist and Diplomat stages based on our assumption that individuals at these stages are not likely found in infrastructure design, operation, and management environments.

Table 2. Ego-development stages considered with the present work.[4]

Stage Name	Methods of influence	Response to feedback
Conventional		
Expert	Gives personal attention to detail and seeks perfection, argues own position and dismisses other' concerns	Takes feedback personally, defends own position, dismisses feedback from those who are not seen as experts in the same field
Achiever	Provides logical arguments, experience, makes task/goal-oriented contractual agreements	Accepts feedback, especially if it helps them to achieve their goals and to improve
Post-conventional		
Individualist	Adapts or ignores rules where needed, or invents new ones, open to discussion of issues and airs differences	Welcomes feedback as necessary for self-knowledge, and to uncover hidden aspects of their own behavior
Strategists	Leads to reframing, reinterpreting situation, so that decisions support overall principle, strategy and foresight	Invites feedback for self-actualization, conflict is seen as an inevitable aspect of viable and multiple relationships

Second, post-conventional stages appear to reveal qualities of people associated with enhanced human resilience and adaptive capacity, which can have positive influence on the SAAL processes in relation to infrastructure resilience. Thus, there is an opportunity for growth and expansion from conventional to post-conventional ways of interpreting experience and interacting with complex systems. Individuals at post-conventional stages can more readily adapt to more complex environments and changes because they are more flexible and have more personal resources available to them. For example, these individuals have the ability to perceive another person's frame of reference and are more likely to respond in a way that is most effective to the task at hand by adapting their message to best be received by the other (Cook-Greuter, 1999, 2004; Vincent et al., 2015).

Many of the properties of post-conventional stages have been correlated with leadership effectiveness across a range of studies reporting similar findings (Cook-Greuter, 2004; Manners, Durkin, & Nesdale, 2004; Torbert et al., 2004; Vincent et al., 2015). Common themes and characteristics include a higher toleration for ambiguity and uncertainty, increased ability to comprehend complexity, and a greater capacity to manage multiple and conflicting perspectives and emotions. These factors are relevant to certain roles and responsibilities in an infrastructure environment whereby people are interacting with other people and with technological systems, and where people and/or groups might be holding different priorities and assumptions. The dynamic interactions can influence potential resilient pathways and outcomes. Whereas the current stage for a given individual represents established psychological structures that can be measured, transitions to later stages are pathways of development representing a potential for growth that can be anticipated and thereby enhance critical infrastructure resilience.

---

[4] Column list stage names by Cook-Greuter and Torbert. 'Methods of influence' characterize how individuals at a given stage tend to interact with others when seeking influence. 'Response to feedback' indicates how individuals are able to receive and integrate information and critique from others (Cook-Greuter, 2004; Torbert et al., 2004).

How do the developmental levels relate to job situations likely to arise in infrastructure disaster scenarios? At Conventional (Diplomat and Expert) levels safety and acceptance come through pleasing authorities and merging/complying with "the crowd" of one's peers on the job. These individuals are more likely to: keep one’s head down; stay out of trouble, don't rock the boat, look good to one's supervisor, just follow the given rules, do their very best to master a defined task.

At the Achiever level individuals are more likely to take initiative, propose novel ideas, understand abstract and complicated systems, map out a rigorous field of possibilities, and search for the most efficient or effective methods.

At later post-conventional stages (Individualist and above) one is more likely to realize that even our best rational efforts are flawed, that human and natural systems are fundamentally unpredictable, and that one should be both open to and prepared for surprise. Moreover, ego development theory suggests that these individuals may be more capable of holding conflicting perspectives and possibilities without stress and moving into "sense and respond" vs. "plan and control" mode when situations are dynamic.

Although individuals tend to operate at a dominant stage (or "center of gravity"), measurements reveal a Gaussian (or normal) distribution among test items. Developmental theories in general draw on Vygotsky's "zone of proximal development" model in assuming that people demonstrate a range of developmental levels across tasks and situations, such that they perform more poorly in challenging or stressful contexts, and perform at their leading edge in familiar and/or supported (also called "scaffolded") contexts (Fischer & Pruyne, 2002; Vygotsky, 1980).

This is particularly important in the domain of critical infrastructure resilience. First, as mentioned, systems failures and unexpected shocks to normal expectations can create stressors that "downshift" an individual's developmental capacity. Second, complex socio-technical systems require collaborative/collective efforts, in which each person's tasks and knowledge is scaffolded by others. In times of complexity, uncertainty, and/or stress, social and communications relationships can degrade, which means that the performance of each individual who relies on others may further degrade. This implies that trust and other forms of social capital actually protect against degradation of both individual and group performance in times of stress.

Discussion and Future Research

A developmental perspective of resilience can have broad application to large-scale natural or man-made disaster scenarios (Masten & Obradovic, 2010). Disaster scenarios and catastrophic events include disruptions to infrastructure critical to public health, safety, and well-being that supports conditions for development to occur. Thus, we propose a method for investigating the relationships between human resilience, development, and critical infrastructure resilience.

The framework proposed combines conceptual frameworks of human resilience, development, and critical infrastructure resilience to form a single meta-framework. The SAAL processes are adapted from resilience engineering concepts and frameworks representing the resilience of a socio-technical system (Hollnagel, 2014; Park et al., 2013; Woods, 2015) as applied to critical infrastructure (Thomas et al., 2019). Common theoretical foundations consisting of cognitive, emotional, and behavioral dimensions of resilience (Mischel & Shoda, 1995; Reich, Zautra, & Hall, 2010) and human development (Cook-Greuter, 1999) serve as a basis for linking the frameworks. Moreover, data from prior research revealing a strong, coherent relationship between resilience and development in adults (Gralinski-Bakker et al., 2004; Hauser, 1999; Westenberg & Block, 1993) further supports our rationale for research linking frameworks. With an emphasis on coupled social and technological systems, we offer a conceptual model a starting point to operationalize an integrated framework of resilient human development and critical infrastructure.

The proposed framework is shown in Figure 2 below. The rows are the four stages of development identified earlier, and the columns represent the four social-technical processes, which are dynamically coupled to human resilience and critical infrastructure resilience (Thomas et al., 2019). The SAAL processes serve as a coupling mechanism linking infrastructure resilience concepts with human development concepts and structures. We posit that endogenous and exogenous properties and processes corresponding to sensing, anticipating, adapting, and learning are progressively differentiated for each stage of development as identified in the first column of Figure 2. Each stage reveals capacities for sensing, anticipating, adapting, and learning that are more enhanced, complex, and integrated compared to the prior stages. We also posit the differences between stages can have a significant influence on critical infrastructure resilience. For example, as an individual's development unfolds from conventional to post-conventional, there is a shift in capacity toward greater autonomy, and a higher tolerance of ambiguity and uncertainty (Cook-Greuter, 2004). The shift can impact how individuals interpret and respond to high degrees of complexity such as catastrophic system failures and disasters. Moreover, a capacity to comprehend complex systems is emergent at the post-conventional levels (Cook-Greuter, 1999), which can impact critical infrastructure resilience.

Figure 2.[5] A framework integrating technical systems' resilience capacities with human meaning-making via the SAAL sociotechnical processes.[6]

At this early stage of arguing for a marriage of developmental theories with infrastructure resilience scholarship we can only begin to map out the potential applications and implications. Clearly there is no extant research that demonstrates that, for example, individuals at or above a given developmental level will perform well at specific infrastructure-related jobs, or respond flexibly to systems failures and other unexpected situations. Here we can only (1) argue that the capacities required for resilient responses map well to the skills articulated more thoroughly in existing developmental theories (in particular meaning-making and ego-development models); (2) show that developmental theories and their assessment instruments have proven to be robust and valid in many applications and contexts.

How are each of the SAAL components effected by developmental factors? To review: *Sensing* is the ability to detect system state variables; *anticipating* is the ability imagine changes in system conditions and state variables; *adapting* is the ability to adjust system performance while maintaining viable operation; *learning* is the ability to absorb, retain, and access knowledge from experience. Below we illustrate how each of these elements relates to developmental factors – but keep in mind that here one's "developmental level" is not simply one's ordinary "center of gravity," but includes the dynamic of the how one actually behaves and thinks in any given moment and situation. For example, a person who normally is open to receiving feedback may be more emotionally "shut down" and defensive in times of stress – exhibiting a lower developmental capacity. Later developmental levels will be better able to monitor both self and social-systems to notice stressor effects, and make efforts to protect against or compensate for them – resulting in a type of meta-resilience that tries to maintain optimal levels of psycho-social resilience in the face of extreme stressors. In terms of each of the SAAL elements:

---

[5] **Note:** The stage names in bold represent changes in labels Cook-Greuter made to her model in 2015.

[6] As development moves from the Expert toward the Strategist stage, each cell describes the internal and external developmental properties representing the SAAL sociotechnical processes – sensing, anticipating, adapting, and learning.

- **Sensing:** Earlier stages may be less capable of perceiving novel information and may "keep their head down" focused on tasks and be less likely to scan for unusual signs. And they may stay silent and defer to authorities or consensus opinion in the face of novel or conflicting information. Conversely, later levels may notice nuances and novel signals, be able to perceive come complex patterns in novel data, be more likely to speak up in dissent from authorities or peers; and they may notice more nuanced signals and patterns in interpersonal and social dynamics.

- **Anticipating:** Earlier levels are less likely to imagine possibilities or scenarios that differ from past experience (or codified procedures); they are less likely to consider the types of complex interactions and feedback loops that lead to unpredictable and chaotic outcomes; they are less likely to take the initiative to actively seek out new information and perspectives. Conversely, later levels are more likely to anticipate more unusual and/or complex scenarios; be more active in seeking diverse perspectives on a topic; and will have the capacity to plan or imagine further into the future, and over wider social and geographic scales.

- **Adapting:** Earlier levels will stick to accepted and well-practiced protocols, fearing punishment, public shaming, or disorientation if they diverge from norms and authoritarian expectations. Conversely, later levels will adapt routine protocols more readily, and have better feedback mechanisms (sensing and anticipating) for continuous fine-tuned adjustment of their actions and plans.

- **Learning:** Earlier levels are more geared to learn from explicit instruction, and from observing and/or imitating others; they are more resistant and defensive to changing their minds or mental models or to receiving corrective feedback. The types of complexity they can learn is limited, for example, to simple associations and linear methods. Conversely, later levels are more eager to learn, improve, and excel; ego's are less threatened by challenges, and corrective feedback is not only appreciated it is sought after. In addition, more complex mental models can be learned, such as complex dynamic systems, ecologies, recursive and fractal structures, etc.; and more complex interpersonal and socio-cultural dynamics can be appreciated and accommodated to.

We posit knowledge of the properties that appear at each stage of development assist with aligning strengths and capacities of individuals with roles and responsibilities for designers, operators, and managers thereby improving critical infrastructure resilience. Moreover, because stages emerge in an invariant sequence over time (Cook-Greuter, 1999; Loevinger, 1976), knowledge of how the properties change at each stage can serve as a predictor of potential outcomes correlating with the SAAL processes representing critical infrastructure resilience. Thus, knowledge of how a person is capable of responding and interacting with complex systems can improve critical infrastructure resilience by providing a more effective allocation of resources. For example, possible responses to varying levels of complexity and uncertainty related to infrastructure disruptions can be informed by an individual's stage of development thereby increasing the potential of aligning resilient system requirements for sensing, anticipating, adapting, and learning with human resilience and developmental capacities.

Similar to the adaptive properties of other human coupled systems that are unpredictable due to novelty and uncertainty introduced by humans (Holling & Gunderson, 2002; Martin-Breen & Anderies, 2011), we posit that meaning-making offers an important dimensional perspective of resilient social-technical systems like critical infrastructure. Thus, another reason for incorporating ego-development in our framework linking people and technical systems is that ego-development theory and model rely on measurement of adult capacity for meaning-making. Moreover, Cook-Greuter's (1999) evolution of Loevinger's (1976) model and O'Fallon's extension (2011) offers a comprehensive and validated method for measuring the adult capacity for meaning-making relevant to the present application. Because stages of development correspond to structures of adult meaning-making, we argue that ego-development is an effective way to account for the third dimension of resilience, in addition to space and time, influencing complex adaptive systems like critical infrastructure.

Further work could propose how each SAAL element breaks down by each of the four developmental levels in Table 2, but the level of specificity we give above, in terms of general trends, better matches the early state of research and scholarship in applying developmental theory to workplace and infrastructure resilience. How might we apply this marriage of the SAAL framework and developmental theory? Again, we can only be suggestive at this early stage, and additional research is warranted.

- Our framework can be used to better articulate the factors that go into techno-social systems (1) design; (2) training; and (3) post-event analysis. The framework supports the consideration of internal (endogenous) and social factors, such as feelings (e.g. confidence, fear, resistance, surprise, trust, respect), expectations, values, and flows of information/communication.

- Post-disaster analysis data could be re-analyzed in the terms of our model. For example each context could be rated according to whether each of the four SAAL elements was early, middle, or late according to the trends we suggest above. This could be done for successful responses and unsuccessful responses, with the hypothesis that successful responses would demonstrate later level SAAL elements.

- The assessment of developmental levels (directly or indirectly) can inform both the expectations placed on workers and stakeholders, and also the appropriate types and goals for trainings and educational opportunities afforded.

- Developmental assessment might be used to inform which individuals are given the reigns and which groups are asked to collaborate closely in response to disasters. The theory suggests that in dynamic scenarios trying to coordinate conventionally-oriented groups with post-conventional groups would only pile on additional tensions.

Here we must add a caution often included when such developmental or cognitive tests are used for "high stakes" decision-making. A single assessment has a margin of error, and any single measurement can capture the complexity of a human being. Such assessments should not be used as the only source of decision making; extreme precautions are warranted when decisions are focused on individuals (e.g. job placement); and more robust results are expected when assessment results are applied over groups, e.g. in assessing the average ability of a team to respond to a critical situation. Moreover, as research indicates that diversity of various sorts is important for team performance (Horwitz & Horwitz, 2007; Nederveen Pieterse, Van Knippenberg, & Van Dierendonck, 2013), relying on any single psychological construct can contribute towards cultural or epistemic ‘mono-culture’ (Bennett, 2015; Mignolo, 2011)

Conclusion

Human resilience, development, and critical infrastructure resilience can have reciprocal influence on one another. The holistic model shown in Figure 2 links resilience and development with technical systems by incorporating the endogenous and exogenous factors influencing the resilience of complex systems like infrastructure. The endogenous properties include the cognitive, emotional, and behavioral factors linking ego-development and human resilience. These factors form a developmental basis for human intentions, motivations, and agency that subsequently influences and informs social-technical processes of sensing, anticipating, adapting, and learning. The endogenous and exogenous properties are both recursive and reciprocal in nature, which means each system can interact and exchange influence in a repetitive manner, and each system can influence the resilience of other coupled systems. Future research designed to identify, apprehend, and validate the theoretical and conceptual frameworks presented herein with empirical data is recommended. Knowledge of the properties and processes corresponding to sensing, anticipating, adapting and learning for each stage of development will ground the theoretical and conceptual frameworks in practical research. A proven operational model can elucidate how each stage of resilient human development contributes unique qualities and capabilities needed by designers, operators, and managers to ensure the resilience of infrastructure critical to public health, safety, and well-being.

Nine Paths of Growth: Integrating Immunity to Change with the Enneagram

Amiel Handelsman[1]

Introduction

In this article, I propose several ways of integrating the Enneagram system of development with Kegan and Lahey's Immunity to Change (ITC) framework. These "meshes"[2] represent the latest step in a broader project to enact my own version of "integrative leadership." In general, integrative leadership means blending together different frameworks[3] for developing leaders by using each framework's unique strengths to supplement the others. Rather than debate which approach is better, we bring them together. This integrative process comes with two prerequisites. First, the frameworks need to share enough core principles to make them compatible. Second, they need to differ in their specific practices – what you actually *do* to develop leaders – because it's on the field of practice that integration occurs.

My own version of the integrative leadership project involves blending constructive adult development, of which ITC is perhaps the most popular expression, with the Enneagram, and doing so in ways that are practically useful and empirically sound. What prompts this is my experience with these two systems over the past twenty years. Both the Enneagram and ITC have shaped my work with leaders and organizations and my own development as a human being. I've found them to be deep, actionable, and versatile. At the same time, I've scratched my head wondering if they might complement each other. This typically occurs while working within one system. In moments of frustration or stuckness, I'll look to the other system for help. I think of this as a methodological SOS call. The good news is that my understanding deepens. The bad news is that nobody else seems to be dialing the same number. So when looking for people to compare notes, I come up empty-handed. Why is this?

My best current answer to this question involves who hangs out with whom – or, more accurately, who doesn't. The communities of practice that have grown around these two systems inhabit different universes. They speak in different languages, operate on different assumptions, and rarely cross paths either in the lab or on the playing field. Interestingly, although the adult development community is a fraction the size of its Enneagram counterpart, I've met far more

[3] I will be using the words "framework" and "system" interchangeably

SOME RIGHTS RESERVED

adult development practitioners interested in the Enneagram than vice versa. Still, the numbers are small, and the hindrances to inter-communal exchanges substantial. On the Enneagram side, constructive adult development isn't even on the radar. Within the adult development crowd, views of the Enneagram are mixed. Although some find the Enneagram personally useful, few use it professionally. Nearly everyone sees the Enneagram as a stepping stone for placing people in boxes, a topic I address later in this article. Therein lies one reason for this article: to open up an initial conversation between two communities that have yet to even go on a first date.

My secondary intent is pragmatic: to offer practitioners of both systems new possibilities for helping people grow up, wake up, and show up. The adult development community seems more likely to find this offer enticing. For this reason, I've framed the integrative meshes as ways the Enneagram can supplement ITC rather than vice versa. Nonetheless, regardless of which community you associate with, I hope you'll find these to be beneficial. Each integration I describe is something you can experiment with in your own development – which is how I like to start – and explore professionally with clients or students. This reminds me of Kurt Lewin, the founder of organizational development, who famously said that there is nothing so practical as a good theory. Could it be even more practical to integrate two good theories?

Some of the material in this article reflects experiments I've undertaken. Other parts offer early maps of territory yet to be explored. In all cases, I assume that readers have at least some familiarity with both ITC and the Enneagram. This will make the reading experience both more enjoyable and more valuable.[4]

The article is organized into six sections.

- The integrative leadership project and my own take on it
- My experiences as a student of the Enneagram and ITC and how these inspired my commitment to integrate them
- Mesh #1: Ignite practice by integrating ITC's "one big thing" commitments with the Enneagram's Virtues and Holy Ideas
- Mesh #2: Connect ITC's Big Assumptions with a deep tradition of archetypes and practices by integrating it with your dominant Enneagram type
- Bonus Mesh. Increase precision in the "dreadful scenario" portion of ITC's Big Assumption by integrating it with Robert Solomon's taxonomy of fears
- Future questions and an invitation to comment

---

[4] For readers interested in learning more about the Enneagram, I suggest checking out the Enneagram Institute. Its web site has a solid orientation to the framework and detailed descriptions of each type. To discover your own dominant type, consider taking the online iEQ9 from Integrative 9 Enneagram Solutions or using the short test and extended chapters in *The Wisdom of the Enneagram*, a book by the Enneagram Institute's founders. For a solid overview of ITC, read Jonathan Reams' "Immunity to Change: A Report from the Field" in the June 2009 issue of *Integral Review*.

The Integrative Leadership Project and My Own Take on It

In 1993 when I entered the leadership development field, the consulting firm where I worked advocated for change that was “transformational, not incremental.” Nearly three decades later, we talk about complexity, VUCA, liminality, and crises of meaning and legitimacy. Although these terms and the world they describe have shifted, the riddle of leadership has not. Both then and now, leaders’ capacity to navigate collective challenges is insufficient to either (a) promote health at every stage of development arising in human beings for the sake of present and future generations or (b) prevent massive institutional, economic, cultural, and ecological failure. This twin framing with divergent tonalities is deliberate. It reflects two voices within me…and perhaps you?

Let me express this paradox differently. On the one hand, by numerous measures, the human species is sinking deeper in mud, and most of us know it. On the other hand, this is happening at a moment in history that offers a gift unavailable to me in 1993: access to a “full deck” of teachings and practices for living a life of goodness, truth, and beauty. From neuroscience to the world’s wisdom traditions, there is no shortage of guidance about how to live and lead. The catch is that these teachings reside in separate orbits, adhere to different validity claims, and attract different pools of people. What I call the “integrative project” is to mesh these frameworks together in ways that are practically useful and empirically sound.

For people whose work involves developing leaders there is also an “integrative *leadership* project.” I see its purpose as integrating, customizing, and make actionable the best approaches to vertical and horizontal development – not for all 7.8 billion humans, but for people coordinating action with others around shared commitments. At team and organizational levels, this project shows up for me as an exciting possibility. In the broader context of systems, countries, and the planet, the word that comes to mind is “imperative.” *We gotta do better than we’re doing now.*

It is within this context that I’ve been exploring how to integrate three frameworks: constructive adult development, the Enneagram, and the field known alternatingly as speech act theory or promise-based management[5]. My experiments in bringing these together have included:

- An unpublished book illustrating each Enneagram type’s strengths and stretches in managing commitments with others, e.g. making requests, responding to requests, renegotiating promises, reporting completion, declaring (dis)satisfaction

- A conference session where adult development professionals explored what their dominant Enneagram type made object for them

- A short book[6] after the 2016 election examining Mr. Trump’s Enneagram type and developmental stage, whose writing was in the end for me a healing act

---

[5] Promise-based management also is known as speech act theory and ontological coaching. It originated in the 20th century philosophy of John Austin and John Searles. The person who interpreted it for organizations was Fernando Flores. The “sibling” field I reference here and will introduce later is Robert Solomon’s taxonomy of moods.

[6] https://amielhandelsman.com/djt-enneagram-offer/

- Most recently, a series of interviews with later stage individuals about their journey to and beyond the Self-Authored Mind through the lens of their dominant Enneagram type

The bulk of this article focuses on the Enneagram and constructive adult development, specifically Immunity to Change. I also offer a “bonus mesh” that draws upon one of the sibling fields of promise-based management.

Before getting into the nitty gritty, I’d like to share elements of my own personal journey that caused me to see these integrations as both important and possible.

My Experiences as a Student of the Enneagram and ITC

My interest in integrating the Enneagram and ITC is inspired by my own experiences as a student and executive coach. This section draws primarily from the former. Each of these two systems has contributed to my personal (and sometimes transpersonal) growth in powerful ways. I’ve also experienced these systems’ limitations and wondered how to make them better. Of course, isn’t this the starting point for every integrative mesh project? We begin frustrated by partial truths that seem incompatible if not contradictory, reinterpret this emotion as a cue to “supplement,” play around with various integrations, and then observe the goodness, truth, and beauty that unfolds (or doesn’t).

Although the Enneagram and ITC come from different traditions, operate in different ways, and attract different people, they have several things in common. First, they are useful in confronting what Ron Heifetz calls adaptive challenges. They assume that exterior behavioral shifts are necessary but not sufficient. Interior skills and awareness also matter. Second, they involve performing subject-object moves on interior narrative structures that live deep in your being and affect every domain of life. For ITC, it’s your Big Assumption. For the Enneagram, it’s your dominant type, its wings, lines and more. Third, they grant a positive intent to these interior structures. ITC calls this anxiety management. Your competing commitment and Big Assumption are signs not of stupidity but intelligent self-protection. For the Enneagram, the aim is to come home to the love that is your true nature. Fourth, both systems reveal to you how, in Kegan and Lahey’s words, you are “screwed.” In its efforts to protect you, your anxiety management system puts the brakes on commitments that matter to you. As for the Enneagram, your dominant type’s noble intent to connect you with love is thwarted by its radical misinterpretation of how to get there. Finally, the discovery is half the goal. Immunity Maps involve deep thinking and feeling and hold high standards for moving from one column to the next. As for the Enneagram, identifying your dominant type is intended to be not a quick assessment but a revealing journey.

ITC and the Enneagram have more in common than might appear on the surface, especially to devoted practitioners of each. Just as important, their strengths differ in ways that make them potential complements. What follows is a brief description of how I discovered this in my experiences as a student of both approaches.

Learning the Enneagram

The Enneagram is an ancient system for *waking up* to your true nature. In the last half century, it has emerged as a modern system for *showing up* in life as competent, reliable, sincere, and caring. Critics note its use for *boxing up* people into rigid categories and *hamming up* justifications for unhealthy behaviors. There is plentiful evidence of both misuses in the actions of people unpacking the Enneagram through conventional and early post-conventional action logics.[7] What remains largely unexamined is the Enneagram's potential for *growing up* people through stages of adult development. Russ Hudson suggests that "Type isn't a 'type' of person, but a path to God." What if each type also provided a path to the Self-Authored Mind and beyond?

The Enneagram contains many layers, folds, and permutations. In addition to your dominant type, you have access to two "wings," as well as points of stress and integration. Right there your inner life touches five of the nine points. If you're boxed in, the container is not one, but five boxes! Now blend in your dominant instinctual type (self-preservation, sexual, or social) and nine levels of health. Suddenly, the Enneagram is a system of great complexity. Yet complexity is in the eye of the beholder. How you make sense of your dominant Enneagram type – and the degree to which your awareness includes the other dimensions – depends on when in the journey of adult development you encounter it. And, as you grow, these encounters work on you in different ways.

My own experience is illustrative. One way to describe my first encounter with the Enneagram is to contrast it with my exposure a decade earlier to another typology, the Myers-Briggs Type Indicator (MBTI). During my senior year of college, I learned about MBTI in a leadership class. My big "aha" was that different people are different, and no style is better than any other. As the guest instructor explained this, I remember feeling a warm compassion arising in me that was utterly novel. Here was a world where being Introverted as opposed to Extraverted was neither right nor wrong, but simply different. Appreciating these differences enables us to circumvent misunderstandings and get along better. This is what the instructor taught, or at least how I unpacked it through my existing action logic. At that time, it was likely centered in Expert attention to mastering the craft of pre-med coursework and dipping into Achiever capacities for reflection, single-loop learning, and openness to feedback.

Ten years later, when I discovered the Enneagram during a coaching course, the experience brought an updated version of that prior "aha" and added new ones. I learned that the Enneagram, like MBTI, delineates a series of types, none better or wiser than the others. Again: people are different, and that's OK.

---

[7] These misuses raise important questions about who helps whom learn the Enneagram for what purposes. Is the Enneagram like nuclear fission material that belongs in certain hands and not others'? Should we teach it only to people at later action logics? One could make a solid argument for this on moral and philosophical grounds. However, on a practical level, the Enneagram is less like uranium than video games. It's everywhere (albeit to a far lesser degree), and restraining its use is impractical. Rather than slow its spread, I would distinguish its uses. At conventional action logics, the Enneagram is good for appreciating difference. This assumes, of course, that teachers introduce it with appropriate caveats, disclaimers and contraindications. I don't know how often this happens, but it presents an intriguing challenge to any Enneagram teacher who accepts the validity of developmental stages.

Yet with the Enneagram the self-typing experience was emotional, even cathartic. When my teacher asked me, “Is it more important for you to be right…or to be safe?” tears immediately appeared. *Safety. This is what I’ve always wanted and concluded I could never find.* Memories appeared of my parents’ divorce at age six, hiding in the closet from suspected (but not actual) burglars as an adolescent, and terror during dates as a young adult that my primal urges would cause me to cross the line. Now each memory gained a radically new interpretation. My self-image as a spontaneous and free-spirited person dissolved in an instant. In its place arose a storyline around safety and trust that had operated on me pervasively yet outside my awareness. *Oh, so that’s what’s been going on all this time! I thought I was a pretty smart guy. How could I have missed this?* Classic subject-object move.

This experience with the Enneagram is not uncommon for people entering later post-conventional stages. Identifying your dominant type doesn’t put you in a box. Instead, it names the box you unknowingly put yourself in every day and offers – or at least hints at – a path out. Alas, in my case, the former stuck far more than the latter. This was not due to an absence of hints about the path out. I was aware of the Six’s Virtue of courage, the Holy Idea of faith, and the Healing Attitude that “maybe this will work out fine, maybe I can trust myself.” I also had read about the path of integration into the Nine’s serene dynamism, and the nine levels of health within type Six, marked at the upper end by being grounded and valiant. However, my teacher, an expert at coaching, not the Enneagram, did not highlight these, and I did not seek them out. As a result, although in theory I knew the Enneagram provided a path to heaven (or at least contentment), in practice I used it to keenly observe my daily sojourns to hell. *Anxiety and distrust? Check. Unfolding potential for courage and faith. Say what?*

Six years later, after a major life trauma, I would discover positive psychology, which propelled me to recognize my own courage and faith. Yet at the moment I first explored the Enneagram, this awareness was absent. It was as though, after mapping my Immunity to Change, I had started to observe the Doing/Not Doing behaviors in Column 2 – and never stopped. This is because the Enneagram lacks ITC’s consistent sequence of exercises for overcoming immunity. There was no standard process everyone follows to “catch” me from falling into the habitual reactions of my dominant type. How different those six years might have been had such a process existed. Therein lies one half of my motivation for integrating the Enneagram with ITC.

Exploring Immunity to Change

I first experienced ITC in 2002 through Kegan and Lahey’s first book, *How The Way We Talk Can Change The Way We Work*. At this time they had not yet begun using the metaphor of the body’s immune system. The four-column exercise elicited the “internal languages of transformation.” Going through this exercise wasn’t creating an Immunity Map. It was “building the new machine.”

This language had an unfortunate impact I didn’t recognize until much later, and it highlights a potential gap in ITC that is present even today with the updated terminology. In those years, one of my primary tribes was a coaches’ book club. When we started reading *How The Way We Talk*, we didn’t make it past the first chapter. At that time in San Francisco’s post-conventional coaching world, nature metaphors were in, and machine metaphors were out. The moment my colleagues saw the word "machine," they had a strongly negative visceral response to the entire book. You might say that Kegan and Lahey's framework was rejected by the group's immune system. (Later in the decade, when *Immunity to Change* appeared, most group members took to it with enthusiasm.)

The impact on me was significant. Four years after discovering vertical development through Ken Wilber, I had finally found a practical way to facilitate it, one created by giants of constructive development. When my colleagues rejected the book, I felt disappointed and alone. Where could I find a micro community of support, a "We" space, for this new system? As it turned out, and for a variety of reasons, nowhere.

Nearly two decades later, people have many places to turn for support. There exists a cadre of certified ITC coaches. There are online ITC communities. Tens of thousands of people have gone through the ITC process. Although there are few, if any, geographically based ITC nodes comparable to many cities' long-standing Enneagram communities, more We spaces are available now than in 2002.

Having said this, there are two areas in which ITC could benefit from an integrative mesh:

1. *Orienting generalizations based on a small number of archetypal patterns*. Although experienced ITC practitioners observe patterns across students' Immunity Maps, the ITC framework has no common language for describing these patterns. It is not unusual for participants to think their Big Assumption is unique to them. After all, they came up with it. Even if two participants discover that their Big Assumptions are similar, there is no terminology for naming these similarities across the ITC community. I suspect that few ITC practitioners see this as an omission. Yet when you've spent time with the Enneagram, it's hard to imagine a developmental journey without such orienting generalizations. This is the benefit of a system with nine numbered types. You can have meaningful conversations with people who share your dominant type. You can explore how other types are part of you. You can learn how your dominant type interacts with other types and discover the synergies and tensions in these combinations. As we'll see in our meshes with ITC, you can also ignite practice using the essential qualities of your dominant type and create rich new paths for naming your Big Assumption. In all of these cases, the Enneagram gives you and others a shared language not available with ITC alone or only through heavy pattern-recognition lifting by the ITC teacher.

2. *A rich tradition of resources that includes explicit adaptations to different personal and professional contexts.* On the one hand, the ITC framework has made traction in many different organizational settings and for navigating a wide variety of adaptive challenges. Kegan, Lahey and colleagues have applied ITC to school transformation (*Change Leadership*), weight loss (*Right Weight, Right Mind*) and what they call deliberately developmental organizations (*An Everyone Culture*). In terms of sheer flexibility, there is no limit to ITC's uses. Yet there is a difference between a framework's adaptability and maps illustrating how to make these adaptations. Here, again, the Enneagram has much to offer. If you want to enrich your self-understanding and relationships with others, innumerable books, videos, podcasts, and online resources are only a click away. I've

personally tapped Enneagram-based guides to marriage, parenting, managing, diversity, and spiritual growth. As mentioned above, I've written a workbook illustrating how different types manage commitments. As with any resources deriving from multiple sources, quality varies widely, so discernment is important, but the tradition is deep and accessible.

To summarize, my experiences with the Enneagram and ITC have prompted an interest in integrating them and a recognition that the benefits flow both ways. One gift ITC offers Enneagram teachers and students is a structured sequence for working with your interior narrative (Big Assumption or dominant Enneagram type). This keeps you in a dynamic tension that nurtures growth and therefore raises the odds of a subject-object move. In return, the Enneagram provides ITC coaches and participants with connection to community, a rich tradition of teachings, and an elegant nine-point framework whose orienting generalizations enrich both individual practice and collective conversation.

Next, by zooming in on the level of methodology, I explore tangible ways the two systems can complement each other in a feet-on-the-ground manner. One involves igniting sustained practice by integrating ITC's "one big thing" commitment with the Enneagram's evocative virtues and holy ideas. The other involves meshing the linguistic framing of the Big Assumption with the core qualities of people's dominant Enneagram type. Then we'll close out with a bonus mesh that adds precision to ITC's dreadful scenario thought exercise.

Mesh #1: Ignite Practice by Integrating ITC's "One Big Thing" Commitments with the Enneagram's Virtues and Holy Ideas

The work of growing up, waking up, and showing up is compelling. It also brings blood, sweat, and tears and can be challenging to sustain. That's why it's useful to have what Daniel Coyle calls "ignitions" to practice. Ignitions include the South Korean girl watching a countrywoman win the LPGA golf championship for the first time and thinking, "I could *be* that" – and then signing up for golf lessons. It's me realizing, after finishing *Sex, Ecology, Spirituality*, that *restoring the biosphere requires personal transformation, the ITP Kata can do this, and I'm going to start it today* – and then each morning, before practice, reminding myself of this purpose, for years. Ignition is people who dedicate their daily meditation to a grieving friend or strength training session to healing intergenerational racialized body trauma.

The notion of igniting practice is an explicit part of ITC and implicit to the Enneagram. Each system could employ ignition to greater effect by integrating strengths of the other. This is the aim of the first integral mesh.

Immunity to Change

In ITC, this ignition shows up in the column 1 commitment. Between *How the Way We Talk* and *Immunity to Change*, Kegan and Lahey raised the bar for its contents. Initially, you generated it by flipping a common complaint. Although this practice worked wonders with complaints, it didn't consistently produce commitments energizing enough to compel practice. That's why in the updated method described in *Immunity to Change,* Kegan and Lahey ask you to identify "one big thing," an *affirmative* change *you* make that is a *must* for you and important to *others*.

What's still missing from ITC are two recognitions: first, that commitments work best when declared anew each day, preferably before and after practices; second, that these declarations gain power when connected to essential virtues wired into your being and/or to purposes encompassing the widest moral span your mind can handle.

The Enneagram

The Enneagram doesn't explicitly include practice-igniting commitments but offers dimensions that, when grafted onto ITC, can enrich people's embodied experience and results. Let's start with what's missing. It's difficult to generalize about Enneagram teachings because there are several major schools with different approaches. However, in the many Enneagram courses and books I've experienced, I've yet to witness a teaching whose standard process includes declaring a "one big thing" commitment. Individual teachers may do this, but it isn't core to the Enneagram system.

The irony is that discovering your dominant Enneagram type reveals "one *really* big thing" and confronts you with the unabashed truth it contains. This discovery arguably reverberates at least as deep in the bones as most column 1 commitments in ITC. Yet there is a difference between exploring something in depth and stating it in a single sentence. There is also a difference between stating your fixation and declaring your commitment to escaping it. This is a gift that ITC offers the Enneagram: the practice of placing into language the core change you are committed to making. Imagine the benefits that would come if Enneagram teachers made this "linguistic turn" a core throughline in their work.

Here is how the Enneagram could reciprocate the favor. Unlike ITC, this ancient system with mystical origins invites you to explore essential qualities of your true nature, a transpersonal translation for "you at your best." These qualities can ignite your practice, especially when blended into your "one big thing" and/or added as stand-alone declarations.

One quality that comes with each type is its "holy idea," the state of its mind when unclouded and in balance. The holy idea of my dominant type, Six, is faith. This is not the everyday condition of my mind or the mind of anyone else dominant in Six. It's a state we occasionally glimpse. Similarly, each type is endowed with a "virtue," the state of its heart when pure and in balance. The virtue of Six is courage. I'm more frequently in touch with this, largely because I've learned to watch for its appearance. In developmental terms, the holy ideas and virtues of the Enneagram are both states that many of us can access temporarily and stable stages attainable by a very small number of people. Greater depth, less span.

The reason many Enneagram students get in touch with their holy idea and virtue is that mature teachers make these core to their teachings. If you stick around, you learn to identify these qualities conceptually and spot them in your experience. Herein lies another gift the Enneagram offers ITC. Column 1 commitments are by definition "big," but they typically involve skills to improve and irritations to abate, not essential qualities to evoke. This reflects the overall intent of ITC: loosening the grip of anxiety management systems, not cultivating virtue.

I've experienced this difference myself. One of my Immunity Maps starts in column 1 with "staying calm when my kids fight." I consider this a "must have;" it matters to my wife and sons;

and it implicates me. So it satisfies all of Kegan and Lahey's updated criteria. Yet look what happens after introducing the virtue of type Six. Now the commitment reads "employing courage to stay calm." This new phrasing isn't just meaningful. It's also inspiring. I *love* the feeling of being courageous, and no wonder: the new commitment includes the behavior I agree to change *and* transcends it by introducing an essential virtue. Anyone who knows their dominant Enneagram type can fold its virtue or holy idea into their column 1 commitment – and then repeat this declaration before each step in the "overcoming immunity" sequence.

In the table below, I list on the left three Column 1 commitments from *Immunity to Change*. On the right I imagine expanded declarations. Each new declaration includes the virtue of a type that is plausibly dominant for that person. This new version also adopts more powerful language, e.g. not "I want to be" but "I will."

Table 1. Expanded ITC commitments

Original column 1 commitment	**Expanded commitment**
"I want to be better at increasing the number of things I delegate in order to have fewer things on my plate." (David, p. 134)	"I will tap truthfulness [the virtue of Type Three] to increase the number of things I delegate in order to have fewer things on my plate."
"I am committed to better manage my emotional state and my expression of emotions." (Cathy, p. 149)	"I am committed to accessing serenity [the virtue of Type One] to better manage my emotional state and my expression of emotions." [Note: Cathy eventually adopts the mantra "I am calm]
"To be a better listener" (Fred, p. 242)	"I commit to tapping sobriety [the virtue of Type Seven] to be a better listener."

This blended approach will work better for some people than others. Not everyone is drawn to access essential qualities, and some will be turned off by the particular virtue or holy idea of their dominant type. In the latter case, finding synonyms that capture the same meaning can help. One source for these is positive psychology. For example, the VIA Character Strengths Survey contains 24 virtues. Each invokes the feeling of "me at my best" that can shift a column 1 commitment from meaningful to inspiring.

Although a solid column 1 commitment ignites practice, there is no need to rely on it alone. You can complement it with declarations based on the virtue or holy idea of your dominant Enneagram type or comparable language from positive psychology. The addition of "stand-alone" ignitions expands your repertoire for sustaining momentum through the "overcoming immunity" sequence of exercises.

One example: dedicating a safe experiment to your holy idea. I recently began an extensive research project whose eventual partners and final products I've deliberately declared "TBD." This is not how I typically do things. It's a safe (and big) experiment of one of my Big Assumptions. Each time I invite someone to an interview and each time I prepare for that interview, I dedicate it to the holy idea of Six, faith. Doing this reminds me that I’m not only overcoming immunity. I’m also enacting health.

Wider Moral Span

In the context they set and commitments they elicit, both ITC and the Enneagram meet you where you are. This compassionate stand, not uncommon in high quality personal growth and leadership development, creates psychological safety. Yet I’ve long sensed something missing: a nudge to embrace concerns larger than you, your organization, or your family. Given the enormous and complex challenges in this moment of history, I consider this a big omission. Both systems allow you to bring in worldcentric concerns but neither prompt this nor build it into the teachings.

For example, in ITC you base column 1 commitments on what matters to you and others. You aren’t introduced to basic distinctions of moral span like “Me”, “Us”, or “All of Us,” much less asked to stretch as far as you can in framing your commitments. Again, this omission in personal growth and leadership development writ large is nearly universal. Ironically, the one group I’ve asked to frame commitments on these three levels was a high school class setting intentions for their senior year. (We used index cards. Everyone filled out three, passed them around the room, and then read aloud cards created by others. It was the emotional high point of the retreat). I’m not suggesting we push people beyond their capacity, but can’t we challenge them to step closer to its edges?

Three interests prompt this suggestion. First, I’ve observed the power of audacious goals that are big enough to include and transcend you and your tribe. Although worldcentric concerns stabilize only in later stages, the act of naming them, even as a future aspiration, can evoke a sense of goodness and nobility in many of us. These sentiments, when embedded in commitments and regularly declared, can light fire in the belly. Their contribution to sustaining practice when the going gets tough can be as potent as that of the Enneagram’s virtues and holy ideas.

Second, if every there were a place to explicitly nudge worldcentric concerns, it’s in communities devoted to growing up, waking up, and showing up. After all, practicing with the Enneagram or ITC raises the odds of expanding moral span (but does not guarantee it, because of multiple developmental lines). You gain greater presence in head, heart, and gut to collective challenges like climate change, the interplay of gender and economics, threats to transatlantic security alliances, the fragility of liberal democracy, and what the late American scholar Albert Murray called “the folklore of white supremacy and the fakelore of black pathology.” This is “growth to goodness.” Most mature teachers of the Enneagram and ITC care deeply about these issues yet don’t integrate them fully into the work. (As an aside, when these challenges shift from threats distant in space and time to dangers at your doorstep right now, as with the current Covid-19 pandemic, what once required worldcentric vision suddenly takes on sociocentric and egocentric dimensions.)

Finally, even as global challenges grow in intensity and immediacy, social media and other collective meaning-making systems are dumbing us down along every developmental line. Such conventional spaces, which are unavoidable outside of monastic life, exert the opposite force as the Enneagram and ITC. They make us less mature, more reactive, and less likely to widen our moral span. I no longer use Facebook, but most people I interact with do, so my public conversations are affected by its algorithms and those of other social media. These exert profound impacts on our minds and nervous systems like fragmentation, polarization and plain unpleasantness. Perhaps it's time to call them what they are: "regression to badness." This raises the urgency of using developmental systems like ITC and the Enneagram to nudge wider moral plan in the commitments people declare.

Mesh #2: Connect ITC's Big Assumption with a Deep Tradition of Archetypes and Practices by Integrating it with Your Dominant Enneagram Type

The second mesh involves integrating the ITC Big Assumption with your dominant Enneagram type in order to connect it to a system of archetypes you can explore and practice. What makes this valuable (if it works!) is the primacy of the Big Assumption in ITC. It undergirds the anxiety management system described in the Immunity Map and forms a big part of the ITC sequence of exercises. When you complete the map, it is the Big Assumption that you observe in action (by watching for Do/Not Do actions), test, and create safe experiments around. So any effort to improve the power or clarity of the Big Assumption can yield positive ripple effects for the overall ITC process.

Assumptions

The integration I propose rests upon the following assumptions:

- Both the Enneagram and ITC allow you to identify a powerful narrative that affects your thoughts, feelings and actions by operating below conscious awareness.

- The form this narrative take varies. For the Enneagram it's an archetypal pattern of sensemaking known as the Fixation of your dominant type. For ITC, it's the Big Assumption.

- Identifying your dominant Enneagram type and naming your Big Assumption both perform a subject-object move on this narrative. These actions allow you to have the narrative rather than the narrative having you.

- Although there are various ways to linguistically construct the Big Assumption, the "If-then" sentence is the easiest to test. More on this below.

- The four-column Immunity Map is one way to identify the contents of your "If-then" Big Assumption. The Enneagram provides another.

- Marinating yourself in the Enneagram before creating an Immunity Map provides access to depths of self-understanding that can enrich each step in the mapping process.

- Big Assumptions derived at least partly from your dominant Enneagram type connect you to a supportive community, tradition, and set of practices.

Phrasing the Big Assumption as "If-Then"

There are many ways to put a Big Assumption into language. Fortunately, ITC provides a particular linguistic framework that is easiest to test: the "If-Then" statement. Here are several examples from *Immunity to Change*:

- "If I am not highly regarded, [then] I will be a failure"
- "If I don't find a way to get things done, [then] I'll stop being valuable"
- "If I feel helpless, [then] there is no way I can be a good listener"
- "If I cannot be in control of the situation, [then] things are likely to get worse"

Testing Big Assumptions structured like this involves two straightforward and logical steps:

1. Keep an eye out in your experience for the action described in the first part of the sentence, which I call the "If" clause. In the above examples, you'd look for times you were not highly regarded, couldn't find a way to get things done, felt helpless, and weren't in control of the situation, respectively.

2. Each time you observe this action, note what happens next. Does the result described in the second part of the sentence (the "Then" clause) come to pass, or not?

In *How The Way We Talk,* the instructions explicitly called for "If-Then" sentences. This is how I learned it. In subsequent years Kegan and Lahey observed that "If-Then" statements sometimes are too dangerous to test, and other structures can still test well. So in *Immunity to Change* they introduced more flexibility. For example, the book includes the following examples:

- "I assume my safest route to success is to perform exceptionally well in ways that are expected and well established"

- "I assume my wife expects me to be able to help her solve the difficult problems she shares with me"

- "I assume a good me is 150%"

I'm basing this mesh exclusively on the "If-Then" structure for three reasons. First, I know it best. Since learning ITC in 2003, every Big Assumption I've uncovered myself or asked clients to uncover has been an "If-Then" statement. Second is timing. I came up with this mesh in 2005, several years before *Immunity to Change* appeared. Finally, the two-clause structure lends itself better to folding in both the Enneagram (as described here) and a taxonomy of fears (as outlined in the Bonus Mesh.)

Optional Methods

Imagine the following scenario: You know your dominant Enneagram type and have found it valuable to your own development. Now, you've decided to go through the ITC process. The first step is to create an Immunity Map. Your goal, by the end of this mapping, is to have an "If-Then" Big Assumption that is both powerful and testable.

Drawing on both your Enneagram type and the Immunity Map instructions, how might you do this? Here are four possible methods:

A. Use your Enneagram type to fill in the "If" clause of the sentence. Follow the instructions for column 4 to complete the "Then" clause.

B. Follow the instructions for column 4 (reverse your Competing Commitment) to fill in the "If" clause. Use your Enneagram type to fill in the "Then" clause.

C. Use your Enneagram type to fill in both clauses.

D. Use ITC instructions to fill in both clauses. This method doesn't integrate the Enneagram, so we won't explore it here, but it remains the default option.

Now, assume that in the Enneagram your dominant type, the one you identify most closely with, is One. This type often goes by The Perfectionist or The Reformer. Let's use this to walk through methods A, B, and C.

For each method, let's ask:

- What possible Big Assumptions might emerge from it?

- What observations can we make about how the method functions, its strengths, and its limitations?

Before we start, let's mix things up to illustrate the actual variation that exists in the world. Rather than have just you try these methods, let's imagine that three different people try them. All have One as their dominant type yet differ in other ways, as real people do. These differences are reflected in their Big Assumptions, which look less like Siamese twins than fraternal twins.

To mix things up further, we'll introduce not three, but six people. For Method A, we'll follow Bob, Jen, and Xavier through the exercise. For Method B, we'll join with Rose, Ted, and Ari. As for Method C, by the time you get here, you'll have a pretty good idea of how this rolls, so we can discern the method's pros and cons without putting any more people's feet in the fire.

Table 2. Method A: Enneagram Type as Observed Behaviors ("If" Clause)

Clause	Source
"If…"	Enneagram type
"then…"	ITC – column 4 instructions

This method introduces the Enneagram after completing the first three columns of the Immunity Map. When you get to column 4, you have a new option for constructing the "If" clause. Instead of simply reversing the competing commitment per the ITC instructions, you bring in your dominant Enneagram type. Taking both steps gives you two optional "If" clauses. Select the one that feels most powerful or draw on both to create two Big Assumptions.

The Big Assumption based on your dominant type can take numerous forms. Here is one example:

"If I stop pointing out what is missing, then…."

Bob, Jen, and Xavier all identify with Type One, so their Big Assumptions start the same way. However, they are different people, and the latter half of their Big Assumptions reflects this. Here are examples of their Big Assumptions in full:

- "If I stop pointing out what is missing, then my friends will abandon me and I'll be all alone." (Bob)
- "If I stop pointing out what is missing, then I'll lose my job, go on welfare, and end up drunk and on the street." (Jen)
- "If I stop pointing out what is missing, then I'll have wasted everything my parents sacrificed and decide to kill myself." (Xavier)

These examples bring forth the following observations:

- You can construct the "If" clause in a variety of ways consistent with your dominant type, but all need to involve specific observable behaviors. The example above could be restated as "If I make mistakes…" or "If stop being serious and methodical…" because both are observable behaviors. What would not work is using a purely interior experience, like "If I am corrupt and defective…" (the Basic Fear of Type One), because this would render the Big Assumption untestable.
- Whereas the "If" clause is derived from your Enneagram type, the "Then clause" – the horrors you imagine – can take an infinite range of forms unique to your life, family, and culture. This ability to fully and authentically engage in the "worst case scenario" thought experiment is an advantage of Method A.

- This is why Bob, Jen and Xavier share the same Enneagram type yet hold different Big Assumptions. All imagine something horrible happening, but the specific horror differs. Same premise, different outcomes.

We can make one other observation about this method: people with different Enneagram types can share the same "Then" clause. As we've seen, Bob, who identifies as One, assumes "If I am not completely perfect, my friends will abandon me and I'll be all alone." Now let's introduce Susan, who identifies as Two. She *also* assumes she'll end up alone, but the route there is different. Her Big Assumption looks like this: "If I stop sacrificing for others, then people will stop loving me, and I'll end up all alone."

In this example, the contrast between Enneagram types is this: "If I am not completely perfect…" (Type One) versus "If I stop sacrificing for others…" (Type Two)

Table 3. Method B: Enneagram Type as Dreadful Scenario ("Then" Clause)

Clause	Source
"If…"	ITC – column 3 competing commitment
"then…"	Enneagram type

Now we flip things around. As before, you can start with the Enneagram, but in this case, you use it to create a "Then" clause consistent with Type One.

Here are three plausible variations based on the Enneagram. Each is based on an expression of Type One's Basic Fear "to be corrupt, evil, or defective" or denial of its Basic Desire "to be good, have integrity, be balanced."

- "If…, then I will become corrupt."
- "If…, then I will be proved wrong."
- "If…, then other people will mess up the order I've created."

After selecting one of these variations, you complete the Big Assumption by inserting the opposite of your competing commitment from column 3.

Once again, we are joined by three people dominant in type One: Rose, Ted, and Ari. As it happens, all three select the first example above, which uses language straight out of the One's Basic Fear: "If…, then I will become corrupt." To complete the sentence, they reverse their competing commitments, each unique to the person. This results in the following Big Assumptions:

- "If I delegate more to my team, then I will become corrupt." (Rose)
- "If I don't complete this task even better than I promised, then I will become corrupt." (Ted)
- "If I stop criticizing people when they make mistakes, then I will become corrupt." (Ari)

A few observations:

- All three people imagine the same dreadful scenario but take different paths to get there.
- I've taken the liberty of inserting "If" clauses that reflect common Type One behaviors. In real life, these three people may not be thinking about their Enneagram type during the ITC exercises. Their "If" clauses could feel disconnected from their dominant type or reflect a wing, integration point, or stress point. Conversely, if such type-specific behaviors were to organically emerge from the mapping process, it would lend credence to the pervasiveness of their dominant type.
- One advantage of this method over Method A is that your Big Assumption builds directly on all of the work you've done in prior columns of the Immunity Map. In contrast, Option One interrupts the natural flow from competing commitment to Big Assumption by grafting your Enneagram type onto the "If" clause.

Once again, people with different Enneagram types may have similar Big Assumptions. In this case, the possible point of commonality is the "If clause." For example, Ted, type One, assumes, "If I don't complete this task even better than I promised, then I will become corrupt." Meanwhile, Amber, who identifies as Six, assumes "If I don't complete this task even better than I promised, then nobody will trust me and I'll bring harm onto my entire family."

The contrast between Enneagram types is this:

"…then I will become corrupt" (Type One) versus "then nobody will trust me and I'll bring harm onto my entire family" (Type Six)

Table 4. Method C: Double Bypass of the Immunity Map, a.k.a. Enneagram Type as Both Clauses

Clause	Source
"If…"	Enneagram type
"then…"	Enneagram type

Unlike the first two methods, this one can work by relying solely on your understanding of your dominant Enneagram type. You can bypass the entire Immunity Map exercise. In this case, what you borrow from the ITC framework is the "If-Then" construction of your narrative, recognition of the Big Assumption as a subject-object move, and the prescribed sequence of exercises for working with the Big Assumption. But the full contents of the Big Assumption derive from type.

A "quadruple bypass" of the Immunity Map is costly. Although this saves time, it denies you the powerful process of working through your anxiety-management system step by step. You don't get to declare a column-1 commitment that is energizing and compelling. You don't get to consider the actions you are taking or not taking that interfere with that primary commitment. And you don't get to experience the special tension between two commitments. These are serious omissions.

Method C works best not by entirely bypassing the Immunity Map but by carrying it almost to completion. Call this the "double bypass" approach. Here is how it might work:

- Complete column one as prescribed
- Complete column two as prescribed
- When you get to column 3, pause before filling in the Worry Box. Ask, "What might my Enneagram type tell me about this?" Use this to complete the Worry Box and then identify the competing commitment. The self-knowledge you've gained from the Enneagram acts here like an electronic screwdriver. It harnesses an alternative power source to produce as accurate a result but with less effort.
- Use your Enneagram type to imagine the dreadful scenario that is behind your competing commitment, as in Method B.

Now that we've explored three methods for integrating the Enneagram into the Big Assumption, let's take the next logical step. What if we were to create a set of "templates" for the Big Assumption that people could refer to when creating an Immunity Map?

Big Assumption Templates by Enneagram Type (Using Method A)

The goal of creating templates of the Big Assumption isn't to bind people or force them down a single road. Instead, our aim is two-fold: first, to give people a cushion to lean against as they go through an emotionally and psychologically challenging process; second, to construct a reliable bridge to the Enneagram's orienting generalizations and many applications.

As we've seen, one gift of the Enneagram is its set of deep archetypal patterns. Let's assume we could build cushions from the fabric of these archetypal patterns. What might those look like?

The possibilities are plentiful. Each Enneagram type has many characteristic behaviors, any of which could come into play here. (Note: because the Enneagram concerns motivations, a given behavior isn't necessarily unique to that type). Below are five examples per type. This is the tip of the iceberg. If you included examples for parenting, partnering, managing, handling conflict, coordinating action, and other domains of life, this table could be a book unto itself. Rather than create a mesh-within-a-mesh, I decided to keep things simple by providing generic examples from the mainstream Enneagram literature. Here they are:

Table 5. Templates for Big Assumptions

Enneagram Type	Template for Big Assumption
One	If I make a mistake, then… If I don't do what is right, then…

	If I let others learn for themselves, then… If I stop criticizing myself, then… If I stop pointing out what's missing, then…
Two	If I stop sacrificing for others, then… If I'm up front about my needs, then… If I cannot get others to totally appreciate my sacrifices, then… If I let someone else do this, then…. If I do something good for myself, then…
Three	If I have not accomplished everything I set out to do, then… If I don't do something valuable right now, then… If I stop trying to impress others, then… If I am not the best, then… If I share what's actually in my heart, then…
Four	If I engage in small talk to build rapport, then… If I act in ways that are not true to myself, then… If I do not express all of my feelings with everyone whenever I want, then… If I find that others feel the same way, then… If I act as if there is nothing wrong with me, then…
Five	If I do not completely understand everything, then… If I speak up where I lack expertise, then… If I stop collecting ideas and start interacting with others, then… If I trust this person, then… If I let this person know what I need, then…
Six	If I do not cover all of the bases, then… If I do not do what is expected of me, then… If I allow something to catch me by surprise, then… If I do not foresee a problem, then… If I trust myself and my own judgments, then…
Seven	If I stop seeking stimulating experiences, then… If I'm not constantly active, then… If I stick with this until it's fully done, then… If I stop taking on new projects, then… If I stay right where I am, then…
Eight	If I have to rely on someone for anything, then… If I stop challenging others, then… If I show that I'm feeling pain, then… If I let down my guard a little bit, then… If I use less force, then…
Nine	If I assert my own perspective, then… If I stop describing the silver lining, then… If I directly confront difficult issues, then… If I get energized and am involved, then… If I act as though I were powerful, then…

Once again, the purpose of these templates isn't to restrict possibilities for self-discovery, but to open them up. If you've explored the Enneagram in depth, you can complete the Immunity Map using the standard instructions, but you don't have to. With these templates, you have a new option.

In summary, this second mesh opens new vistas in working with Immunity Maps to uncover Big Assumptions by both including ITC's inherent strengths and transcending them through inclusion of gifts from the Enneagram. The ITC strengths preserved are a sequential process for discovering your immunity to change, the compassionate insight that this immune system stems from a noble motive, the framing of anxiety management, and a structured series of exercises for overcoming your immunity. To this mix we blend in complementary attributes from the Enneagram: archetypal patterns for linguistically framing the Big Assumption, a potentially smoother path through the mapping process, orienting generalizations that invite new forms of conversation, and access to a rich tradition of teachings and practical applications.

Bonus Mesh: Increase Precision in the "Dreadful Scenario" Portion of ITC's Big Assumption by Integrating it with Robert Solomon's Taxonomy of Fears

This mesh reaches beyond ITC and the Enneagram to embrace a set of distinctions from the late philosopher Robert Solomon. Solomon traveled in similar circles as key figures in promise-based management, the third leg of my integral leadership project. For this reason, and because it's short, I'm calling this a "bonus mesh."

Here we set our sights again on the "Then" clause of the Big Assumption. As seen in the preceding examples, Kegan and Lahey insist on high standards for this clause. It needs to represent a really dreadful scenario, something that no one would lovingly will upon themselves or others. In other words, it involves an outcome you fear.

Some people – indeed, some Enneagram types – find it harder to identify their fears than do others. For these folks the act of naming a dreadful scenario presents a formidable challenge to completing the Immunity Map. What support might we introduce that is commensurate with this challenge?

Let's assume that you've used Method A above and, perhaps, a template for your type to construct the "If" clause of the Big Assumption. What might aid you in completing the sentence? Here we turn to Solomon, who introduced a set of distinctions around fear. These distinctions have an added benefit. You can use them if you don't know your Enneagram type or care about the Enneagram at all. They are equally useful for completing an Immunity Map by the book (save this mesh).

In his book, *The Passions*, Solomon offers a taxonomy of moods, which he describes as assessments or judgments we make about the future. We can also say that moods are to emotions like climate is to the weather. However you define them, Solomon's moods include many that fall under the umbrella of fear. The table below shows five:

Table 6. Taxonomy of Moods

Mood	Definition
Anguish	Fear of something I will do
Despair	Fear of something global that will happen to me
Anxiety	Fear of something cosmic happening
Dread	Fear of something unknown happening
Fear (proper)	Something specific that will happen to me

When I first came across this list, I had already begun exploring the role in my life of fear, which is central to my dominant type, Six. Solomon offered me a way of breaking fear down into its many shades. As with any powerful set of distinctions, this one gave me new language to describe my experience. It made me a more competent observer.

This ability to discriminate between variations of fear is equally valuable in completing Big Assumptions. Instead of simply asking yourself "What dreadful scenario do I fear?" you can explore five different types of scenario: anguish, despair, anxiety, dread, and fear. This opens the door to many more possibilities. It may be just the boost you need to finish fleshing out your Big Assumption.

The expanded table below provides examples of how this may look:

Table 7. Taxonomy of Moods with Examples

Mood	Definition	Example
Anguish	Fear of something I will do	"…then I will make a fool out of myself" "…then I will go crazy" "…then I will kill myself"
Despair	Fear of something global that will happen to me	"…then my career will be over" "…then no one will ever love me again" "…then I'll never earn another dollar"
Anxiety	Fear of something cosmic happening	"…then everything will turn out horribly" "…then the world will collapse" "…then God will punish me"
Dread	Fear of something unknown happening	"…then something horrible will happen" "…then something I've always been afraid of will happen" "…then we'll experience a sudden shock nobody expected"

Fear (proper)	Something specific that will happen to me	"…then people will hate me" "…then my boss will fire me" "…then my partner will dump me"

In summary, imagining a dreadful scenario that completes your Big Assumption is far too important a project to be left to chance. Just as in Rome, you do as the Romans do, in the land of fear, it helps to speak the language. Enter Robert Solomon. His taxonomy of moods teaches us that there isn't just one type of fear. There are five. This awareness gives you a leg up in envisioning the catastrophic "Then" clause. Coupled with a strong "If" clause derived from the Enneagram, it produces a Big Assumption worthy of its name. Immunity Map complete!

From here you move onto the next enterprise: overcoming your immunity to change. For this venture, the early integrative meshes have you prepared are useful. ITC sets you in the right direction with its sequence of exercises for working with your Big Assumption, and your Enneagram type's essential qualities ignite your acceleration into practice.

Reflection and Future Questions

I opened this article declaring two intentions: first, to initiate a conversation in which the adult development and Enneagram communities could "break bread" together, an occasion for which I'm offering my services as maître d'; second, to provide practitioners, especially of ITC, with a few specific new methods for developing leaders. Think of these as appetizers to stimulate the palate.

I'm now reporting completion.[8] How did we do?

The assessment is yours to make, and below you'll find an invitation to share it. Rather than weigh in on this question myself, allow me to provide a few reflections on what this was like to write. The first draft, now fifteen years old, was born quickly and in a spirit of naming what seemed obvious, at least to the author. Like the discovery late in the history of the suitcase that *of course it should have wheels*, so came that first intuition about ITC. *Of course there should be one Immunity Map for every Enneagram type and a menu of fears for the Big Assumption*! Fast forward to spring 2020 when I realized that the initial mesh actually was conjoined twins needing to be separated. Fortunately, that operation turned out far simpler than its medical analog, which is probably why I'm a coach-cum-writer rather than the physician my family originally hoped I would become.[9] In fact, the most challenging part of this update was interrogating two original assumptions about what I came to name Mesh #2: first, onto which clause of the Big Assumption to graft the Enneagram; and, second, how to accomplish this without damaging the integrity of the overall mapping process. On both questions, it turns out, I ended up precisely where I started, but the rigor of the procedure raises my confidence that the mesh will prove useful for people other than the author.

---

[8] The phrase "reporting completion" has a specific meaning in the field of promise-based management. It's the important and oft overlooked step where the person who's promised to bring about a particular What by a specific When says to the "customer" of this promise: *I'm done*. This is the cue for the customer to say thanks, assess what they've been given, and declare themselves satisfied or dissatisfied. Every Enneagram type has strengths and stretches in these steps, and arguably the entire framework calls forth growth in the mental demands it places on both parties.

[9] This opens up yet another can of worms that, if not resolved by the new interview project, may yet nudge me into completing my long-gestating developmental autobiography.

One final reflection about sharing the life experiences underlying these meshes. The words I've used to describe them are less memories than reconstructions. Writing them has been an excavation into layers of emotion and sense-making buried beneath the foundation stone of my awareness. Although I appreciate the discoveries, a slight change in site preparation or equipment could have turned up very different interpretations. In simpler terms, I *think* this is why these meshes grabbed ahold of me, but I wouldn't wager more than a week's wages on that thought.

Let me bring this to a close by describing where I *would* direct that wager. If you're looking for a big upside, zoom out from this article to the larger project of integrating constructive adult development as a whole with the Enneagram (and promise-based management). Here you'll find many rich possibilities for waking up, growing up, and showing up that simultaneously reduce the risks of boxing up and hamming up. This being a place of learning rather than investment, allow me to shift from the language of ROI to the language of inquiry. What follows is a series of questions animating my interest in the larger integrative leadership project. Perhaps one or more of them will entice yours.

1. How well do Enneagram teachings meet people where they are developmentally – and how could they do this better?

2. How can the Enneagram help (or hinder!) the journey toward Self-authored Mind and beyond?

3. How does your developmental stage, when encountering the Enneagram, shape how you "use" it?

4. What might the life experiences of later stage people reveal about post-typological Enneagram awareness?

5. How does the internalization of others' perspectives (the Socialized Mind) differ by Enneagram type?

6. What orienting generalizations can we make about how people with different Enneagram types grow into the Self-Authored Mind? The Self-Transforming Mind?

7. How can we customize the adult development field's best practices to Enneagram type?

8. What type-based idiosyncrasies persist in the conversations and meaning-making of later-stage people?

Invitation to Comment

I invite you, dear reader, to send your thoughts my way. What new possibilities does this article reveal to you? What experiences have you had that (dis)confirm its core assumptions? What ideas do you have for improving these meshes or creating new ones? And if you actually *do* want to make some form of investment, what do you have in mind? Email me at amiel@amielhandelsman.com.

Possible Mistakes of Late Action-Logic Actors in a Polarized World

Bill Torbert and Aftab Erfan[1]

Last summer, when we began trying to map the possible mistakes of late action-logic actors, the world was not as polarized as it is today. There had been no global debate on mandatory face masks, or whether people had a right to gather in church in the midst of a deadly pandemic. Nor had millions marched after the killing of George Floyd and called for defunding of police, only to be confronted by further police brutality in some places. Our organizations, communities and families had not gone through the upheaval of 2020. Nevertheless, we had plenty of examples of polarized situations and our own attempts to be of use in these situations. We both felt that, in spite of each of our longtime commitments to personal, organizational, and social development toward complexities of thought and simplicities of awareness that can bridge social differences, and our attempts at creating mutuality as an antidote to polarization, we had often fallen flat on our faces. How could we have gone wrong in so many ways, we asked ourselves? And would it be of benefit to ourselves and others if we studied and shared the patterns of our mistakes?

Thus began an attempt at aggregating our phenomenological, first-person experiences and reflections related to this topic, in order to share them at the September 2019 Growth Edge Network Conference. This being a gathering of many late action logic actors, we planned to expand our sample size and analysis based on the participants' responses and additions. This article now reflects such changes, including, at the end, three later e-mailed reflections. We are delighted by the offer of *Integral Review* to publish the current version of the essay and we invite further responses from readers of this essay.

At the outset of our conference presentation and dialogue about this topic, we admitted to our audience that the announced title of the session demonstrated one of the mistakes to which late action-logic leaders are prone. When we had proposed the session, we had called it "Common Mistakes of Late Action-Logic Actors". Upon actually getting serious about planning the session, however, we very quickly realized that we had no empirical research on how *common* such

mistakes were. We were largely extrapolating based on our own limited experience and some observations of those around us. Hence the revised, more humble title “Possible Mistakes of….”

Possible Late Action-Logic Mistake #1

> *Overconfidence in one’s ability to accomplish one’s initial vision, based in part, paradoxically, on one’s humble ability to correct one’s subsequent path based on one’s openness to feedback.*

During our preparation, we had next realized just how ambiguous the word “mistake” is in any developmental context. At earlier action-logics with short time horizons and concrete goals, as well as little sense of longer-term purposes and strategic plans, a particular action that fails to achieve its goal is likely to be perceived, quite simply, as a ‘mis-take’ (a ‘take’ – an action – that ‘mis’ses its immediate mark). At a later action-logic, the same action may be viewed less as a mistake and more as one of dozens of initiatives necessary over time – to generate the feedback about ‘local’ conditions that will eventually be recognized as the early part of the path toward realizing the ultimate purpose. From this difference in how persons at different action-logics may interpret a mistake, we can infer:

Possible Late Action-Logic Mistake #2

> *Too much attention to long-term purposes and outcomes and too little attention to creating a culture and leadership development process that attunes more and more participants to the value of mistakes in the service of purposive learning.*

Another way of thinking about mistakes late action-logic actors may commit in a polarized world, which raises the stakes and the tension, is to delineate mistakes that early action-logic actors are likely to make. Later action-logic actors are much less likely to make such mistakes, except when a situation ‘triggers’ them to fall back.

Actors at the earlier action-logics (Opportunist, Diplomat, Expert, Achiever) are likely to use forms of unilateral power to try things, which do generate common mistakes, as the following table succinctly (and very incompletely) suggests.

Table 1. Common Early Action-Logic Mistakes

Action-Logic	New Type of Power Available	Relationship to Feedback	Common Mistakes
Opportunist	Coercive	Rejects altogether	Damages & loses other’s trust
Diplomat	Charming	Agrees in order to make others happy	Can’t critique in-group
Expert	Logistical	Accepts only from masters, Data has final word	Fails to see own axioms or others’ perspectives

Achiever	Productive	Welcomes single-loop feedback	Believes goal justifies means

Actors at the later action-logics generally avoid the common mistakes of those at the earlier action-logics, because they increasingly exercise mutual types of power and inquiry. Their increasing ability to offer and receive double-loop and triple-loop feedback permits them and the teams they are working with to transform in the midst of action. Thus, in general, they act in trust-enhancing ways rather than trust-diminishing ways. However, they are susceptible to fallback to earlier action-logics, at which times they are susceptible to committing the early action-logic mistakes. A significant proportion of so-called 'late action-logic mistakes' are probably committed in states of fallback.

Possible Late Action-Logic Mistake #3

> *Late action-logic actors may commit mistakes typical of early action-logic actors under conditions that trigger fallback.*

However, there are different, more subtle kinds of mistakes endemic to the later action-logics as well.

Table 2. Possible Later Action-Logics Mistakes

Action-Logic	New Type of Power Available	Relationship to Feedback	Common Mistakes
Redefining	Visioning	Offers critical, structural, double-loop feedback	Can sabotage own power in "idiot collaboration"
Transforming	Praxis	Welcome receiving as well as offering double-loop feedback	May not quickly recover from fallback
Alchemical	Mutually-transforming	Plays the action-logics like musical instrument, generates transformational "shocks"	May overheat situations with single-, double-, or triple-loop feedback
Ironist	Liberating Disciplines	Creates organizational systems that generate single-, double-, or triple-loop feedback	?

One possible mistake of the Redefining action-logic is to engage in the memorably-named practice of 'idiot collaboration.' By this, we mean holding the value of collaboration as an ideological absolute, a decision process to be used in all cases. This is one of the kinds of self-contradiction that the Redefining action-logic can fall into, due to its relativizing recognition that no philosophical logic, nor psychological action-logic, can prove itself true to someone inhabiting another action-logic. Collaboration therefore seems necessary on every decision in order to properly respect all participants' perspectives in a process. But this is not feasible, nor desirable, given the time-constraints and commitment-limits inherent in any project, as well as the impatience with such a process typical of the early action-logics. ‘Idiot collaboration’ refers to the self-contradictory process of creating an absolute in the name of relativism. In so doing, the person at this action-logic mutes their own discretion and power, a serious mistake.

Possible Late Action-Logic Mistake #4

> *The Redefining action-logic may overgeneralize the virtues and efficacy of pure collaboration in all decisions.*

In each case of transforming from one action-logic to another, there initially tends to be a disdain for the previous action-logic, as part of the cognitive-emotional differentiation from that action-logic. Because the Redefining action-logic is the first that recognizes that we all act through our (different) action-logics, it may lead to an illegitimate sense of superiority and arrogance in regard to all of the prior action-logics. This sense of superiority is illegitimate in two senses: 1) in that persons who are just beginning to explore the implications of the Redefining action-logic often continue to operate from earlier action-logics a great deal of the time; and 2) in that, by favoring their new-found capacity for offering critiques of earlier action-logics, they are overemphasizing the ‘deconstructive’ aspect of transformation and underplaying the ‘reconstructive’ initiatives necessary for successful transformation.)

Possible Late Action-Logic Mistake #5

> *Actors at the Redefining action-logic may disdain and critique the unconscious absolutism of the earlier action-logics, while not noticing it in their own tendency to engage in absolute relativism.*

In contrast to the realistic/materialistic tendency of the early action-logics, actors at the Redefining action-logic can develop a deep commitment to a more idealistic/spiritualistic vision of life. They may tend to dismiss the material realities that impact others (and themselves). For example, first-person ‘mindfulness’ practice may become the solution for all life problems, along with an implicit or explicit dismissal of second- and third-person disciplines for addressing ethical dilemmas and structural, societal issues of economic and political injustice.

Possible Late Action-Logic Mistake #6

> *The Redefining actor may start caring about the spiritual and act dismissively about the material reality that impacts self and others.*

The inefficacy associated with these performative contradictions can gradually motivate a person to evolve toward the Transforming action-logic. This action-logic realizes that in a human world characterized by multiple action-logics, few of which even recognize the possibility of other action-logics or the possibility of exercising mutual power, we need to inquire-in-action in each new conversation, new setting, and new project. A new kind of question arises: Which action-logic and type of power (or which blending of types of power) is it most timely to exercise when? To even approximate effective action consistently, it is necessary to work, not only with a theory of individual action-logics, but also with an analogous theory of event action-logics, and with attentional disciplines which allow one to see incongruities in the moment of action and to act reliably with theory-and-practice-reconciling praxis power.

Possible Late Action-Logic Mistake #7

> *The Transforming actor may have developed theory and skills for working with self or a single other individual (as in coaching) in a timely way; but may as yet have little theory or associated practice skills for intervening in a timely way at the organizational or historical scale.*

Even if the Transforming action-logic actor is working with some kind of organizational development theory, strategizing action using both individual and organizational development theory is very difficult to do in reflection, and all the more so in the midst of action. Even more difficult is estimating how historical eras transform, since one has often lived most of one's life in but one such era. Thus, leaders at the Transforming action-logic are often as shocked and stymied as anyone else by sudden social changes, such as the Black Power movement of the late 1960s, the #MeToo movement of the late 2010s, and the Covid-19 Pandemic cum Black Lives Matter movement of 2020.

Possible Late Action-Logic Mistake #8

> *A change in Zeitgeist or historical epoch is initially likely to frustrate a Transforming actor's efforts at timely action.*

What some gradually realize is that, in spite of their theory of transformation and their well-intentioned efforts to practice it, they are in fact repeatedly – nay, constantly – falling back to earlier action-logics in their daily life. Some kind of unfamiliar exercise of awareness– some kind of meditation-in-action – is necessary if we are to find the post-cognitive attention that can, in real-time action, trace our own and others' thinking, feeling, acting, and impact on the presenting situation and assess the degree of efficacy and mutuality that is being generated.

We begin to seek out – not just single-loop feedback that changes specific actions to improve the likelihood of reaching a goal, and not just double-loop feedback that can change our strategy or action-logic – but also triple-loop feedback that can awaken a 'bare' attention or 'pure' consciousness, again and again and again. This requires a humble, comic, lifelong, spiritual, relational, Alchemical commitment to a task never completed. Only this commitment and developing capacity to offer and to receive triple-loop feedback provides traction at historical moments of changing paradigms.

Whereas the Transforming action-logic can fool itself about how often and for how long it experiences reality in a fallback mode, this is less likely at the Alchemical action-logic because its primary practices involve testing how many of the four 'territories of experience' (outside world, sensation of one's own behavior, thinking/feeling, and bare attention) it is in contact with at a given moment. What is more likely at the Alchemical action-logic is that one gets vilified, ostracized, hunted and killed for creating so much disruption in people's early action-logic habits and assumptions (e.g. Socrates, Jesus, Gandhi, Martin Luther King).

Possible Late Action-Logic Mistake #9

> *An actor at the Alchemical action-logic may disrupt early action-logic habits and assumptions to such a degree that people react violently.*

But does getting killed necessarily count as a mistake? Socrates, Jesus, Gandhi, and Martin Luther King all knew that they were risking death every day and quite deliberately continued to do so. They and their visions are remembered and are inspiring to this day because of what they were willing to die for – a kind of mutual, non-violent action inquiry.

The repeated references to fallback to earlier action-logics in the previous paragraphs invite several additional comments. First, by no means all early action-logic behavior by someone with a later action-logic center-of-gravity represents fallback, or a mistake. It may represent a calculated attempt to engage a person or organization at their earlier action-logic center-of-gravity, in order to establish initial contact and trust as a basis for a conversation or project that can gradually transform toward later action-logics.

Second, fallback is not the only source of 'mistakes' at the later action-logics. Each later action-logic occupies an incomparably larger 'territory' than the earlier action-logics, not only because it includes the territory of all the earlier action-logics, but also and primarily because it recognizes a much vaster realm of possibilities in its own right. Whereas the early action-logics through Achiever operate in the historical, durational dimension of time, the later action-logics gradually become familiar with two more dimensions of time – 'presence in the present' and the 'volume of all possibilities.' But, during one's long apprenticeship in each of the later action-logics from Redefining on, there are many opportunities for mistakes. During the apprenticeship period of exploring a new action-logic, a person or an organization will often 'get lost' among the many possible responses to the moment, or may mis-estimate the energy charge of a particular response one chooses.

Possible Late Action-Logic Mistake #10

> *During the apprenticeship in each action-logic, one often tends to get lost among the many new possibilities for action that become available and may act ineffectually.*

Furthermore, a person may evolve to a late action-logic along just one or two lines of development. In such a case, the person's non-mutuality along other lines of development reflects their early action-logic in that realm. (Think Picasso's alchemical treatment of shapes on canvas, in contrast to his opportunistic treatment of the women in his life.) This uneven development results in a sharp dichotomy between the light and the dark sides of the personality.

Possible Late Action-Logic Mistake #11

> *Uneven development across different lines (practical, cognitive, emotional, ethical, aesthetic, spiritual) can lead to a dichotomy between unilateral and mutual action in different spheres.*

A final kind of mistake that we have experienced at later action-logics is the mistake of engaging earlier action-logic actors in a fashion that is too peer-like, too I-Thou, early in the relationship. An attempt to clarify mutual boundaries may be interpreted as a violation of boundaries. This mistake may be motivated by a spiritual loneliness on the part of the late action-logic actor, and may be received as a threatening, seductive, or manipulative pre-mature intimacy by the early action-logic counterpart. Sometimes, this breach is resolved almost immediately by either party making it discussable and by a joint establishment of agreeable boundaries.

Possible Late Action-Logic Mistake #12

> *A late action-logic actor may prematurely seek a late action-logic relationship with another, arousing suspicion and withdrawal by the other.*

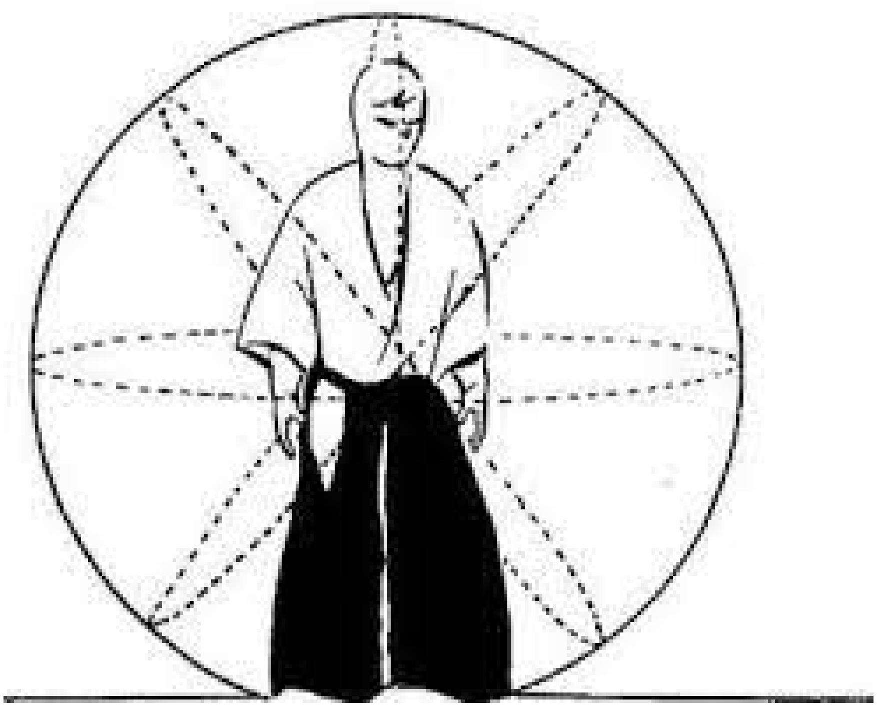
We would like to end by thanking the participants at the original Growth Edge Network session for raising many questions and offering various illustrations of possible late action-logic mistakes in a polarized world, which we have tried to incorporate in this paper. There are undoubtedly more such possible mistakes, and we encourage readers of this article to suggest some. Indeed, we have already received the following suggestions about additional 'possible mistakes' on the GEN website since our conference conversation, reproduced here with permission from commentators.

> **Yotam Schachter:** I want to add one category of mistake that I don't recall hearing in the session itself. Once someone has firmly established the capacity for double-loop learning, then a particular discernment is required in each situation: What loop should I feed this information back into? Is this cause for single-loop or double-loop learning? Do I rethink the whole project, or just tweak the implementation? It's a new mistake only available at higher action logics to double-loop learn from something that only really requires single-loop learning.
>
> **Bill T.:** Hi Yotam, I'm very glad you have reminded me of this particular mistake, quite common in the early period of recognizing the value of double-loop feedback: namely, the implicit or explicit denigration of single-loop feedback and learning. In fact, a single-loop behavioral correction is what is appropriate in the vast majority of instances, and the art of offering or acting on such feedback continues to be an important discipline to practice.
>
> **Jan Weetjens**: One question/suggestion I would have in terms of "mistakes" of later action-logics relate to some of the mistakes that are listed in the paper (superiority, issues with boundaries, ignoring (others') concrete life challenges, etc.). While people may have entered late action logic, they may still be caught in unresolved aspects of their shadow side. As Ken Wilber would say, they may have "grown up", but they may still have work to do to "clean up," or to "wake up."

> I would say that two aspects would deserve particular attention: the first is narcissism. My sense is that late action logic can actually have the effect of bolstering (rather than dissolving) the egoic mind, especially in the early late action logic stages. Some of the "common" mistakes (such as superiority) would point to that. The good news, though, is that, given enough time for ego to run into the stubbornness of reality (and suffering as a result), the person may outgrow this "mistake."
>
> The second, and more dangerous, "mistake" could be the patriarchal mind, or the "guru" mind, where the person positions him or herself as the one who knows, expecting others to surrender their capacity for discernment and agency. Unfortunately, we see all too many headlines in the press of extreme cases where this phenomenon led to abuse of power and violation of victims. Contrary to the narcissism (which only requires suffering of the ego to be dissolved), the patriarchal mind-frame triggers suffering of others, and can take a long time to be unmasked and dissolved.
>
> **Aftab E:** Thank you Jan. I couldn't agree with you more and I worry about these very serious and dangerous tendencies among post-conventional leaders. Our Mistake #1, referring to our own over-confidence, was meant to be a tongue-in-cheek reference to the kind of arrogance you talk about here. Perhaps it was too tongue-in-cheek.
>
> **Dimitri Glazkov:** I am not an expert on others. I am only an expert on myself. My observation with my own development is that the stages didn't arrive in a neat stepping diagram. A metaphor that comes to mind is that of a tool belt. I have various meaning-making models (conceptually similar to Bill's action-logics) available to me, some are less familiar than others. I choose them according to the situation. Intention, habits, stress, fatigue influence these choices. Sometimes the choices are so fluid and instinctive that they almost seem to combine (like Achiever with a tint of Opportunist, using action-logic terminology). My own sense is that the number of the models I have is quite small, but the combinations of them produce the impression of many more.
>
> My self-development challenge is two-fold: I continue to grow my edge and seek out new meaning-making models. At the same time, I work to be more intentional in what I pick from my tool belt in any given situation and have my choices be less influenced by habits, stress, and fatigue. That latter part is what comes to mind when Jan talks about "clean up" and "wake up", and shadows. A "mistake" in this context sounds like a gap in intentionality.

In conclusion, each different action-logic is, in effect, playing a significantly different kind of game from the others. Each of our moves is likely to be interpreted differently in several different ways by the other players. Early action-logic players assume all are playing a common game. In actuality, continual effort is required to transform the event into a shared game. This is so at each scale of relationship – whether between marital partners, among organization members, or among citizens of a nation. Failure to create greater mutuality generates greater polarization and distrust. To our knowledge, no one, nor any community of inquiry, has yet ever succeeded in creating a game that seems developmentally fulfilling for all the participants across generations.

The writing of this paper has been a reflective and playful exercise in mapping and typifying mistakes as a way of inviting open conversation and critique of later action logics. While it is probably not very important that mistakes be mapped and typified in a systematic way, it *is* very important that they are discussable among the members of communities of inquiry dedicated to personal and societal development. The challenging and potentially transformative times we find ourselves in call for honesty about our idiosyncrasies as well as our collective illusions, blindness, and patterns of self-deception. To not engage actively in these conversations would be a mistake.



Aikido and the Pursuit of a Better Life

Mark Shraga[1]

Introduction

When I first stepped onto the Aikido mat in 2010, I was an intensely cognitive person with an abundance of conceptual structure around how to live a ‘better’ life. I had already built a couple of successful businesses in telecommunications and had employed learnings from across a broad spectrum of human development to handle myriad challenges. I had set up my Coaching company Brighter Lives in 2008 as a vehicle for focusing on my ongoing personal development whilst also holding myself accountable both to a professional standard and to the clients I would help along the way. I was however, becoming profoundly aware that issues from my early life, a plethora of setbacks ranging from poverty to being fatherless and subject to intensive bullying until I was 16, were clearly restricting my potential.

I had always had a vision of a better life, and a powerful sense of the possible, driven by curiosity and a passion for connecting to others. I would invariably find that however much ground

---

[1] **Mark Shraga** is an entrepreneur in the telecommunications industry and a Coach Practitioner. He runs an Aikido club in London, holds the rank of 2nd Dan and leads group sessions on ‘Aikido and the Space for Personal Evolution’ for businesses and the wider Aikido community. Mark’s MA (2015) was in Applied Coaching from The University of Derby, where he researched ‘Towards a trans-disciplinarian approach to embodying conscious choice and awakening self-authorship in the client.’

SOME RIGHTS RESERVED

I would gain in the pursuit of my goals and dreams there would come a time when the spectre of my early life would throw a spanner in the works. Since arriving in London in 1998 I had spent around 12 years studying various meditative processes and embodied practices from meditating with Sufis to becoming a pupil of the Alexander Technique. I eventually realised that the core problem was that my body was riddled with fear and fearful patterns. These patterns were obscuring my search for a better understanding of how to live a fuller and more enlightened life, turning me into a walking contradiction at times; quite frankly I was getting sick of myself. Between 2013 and 2015 I would pursue these patterns further during my Master Degree in Applied Coaching by looking at how fear impacts our ability to process information, and how this knowledge could be utilised to help people develop towards self-authorship and beyond; assisting the cycle of moving from the implicit to the explicit, from subject to object.

As I looked around the Aikido dojo, on that first occasion, I could see adults of various ages doing things with their bodies that seemed wonderous and scary. It stimulated in me contradictory feelings of needing to leave immediately whilst also wanting to throw myself ‘head-first’ into it. As my curiosity began to fire up, I found myself being inducted into a supremely counter-intuitive life-long learning experience; failing forwards as way of being a better human being. For me Aikido was the catalyst that enabled me to transform years of cognitive understanding and deep internal conflict into a much more fluid sense of being and doing in the world. Every lesson was an opportunity to be challenged down to my atoms and rebuilt again in the application of principles I was quick to grasp but slow to embody. I was in the process of becoming increasingly aligned with my deepest values and grounded in the bodily knowledge that, at my core, I had the capacity to be ‘ok’ regardless of what life throws at me (particularly when I was literally being thrown on the mat).

I was beginning to see that the more I could become ‘ok’ in my body, and reduce the ways in which I would go into a fight or flight state, the better my ability would be to honour my deeper core values and ways of being in the world with others. Essentially, my body was enabling my mind to be as fully intelligent as it dreamed of being. I still experience intense moments of confusion and frustration, but these are now fused with an awareness of the illumination that will follow if I am prepared to be courageous in the face of the unknowable moment. In this essay I will explore how the qualities of Aikido as a lifelong physical, emotional, mental and spiritual (PEMS) practice, can support us in facing the challenge of developing our potential regardless of the obstacles we face in day to day life.

An Embodied Approach to the Theory of Mind

The most fundamental thing that I have come to understand about Aikido is that it operates on the basic principle that all human conflict arises out of a confusion of compound illusions, where both parties believe their own separate piece of reality to the exclusion of the others. Aikido works at a deep level in the body to create a grounded emotional intelligence that is indispensable in every area of our lives. The insights from practicing Aikido can help shed some light on a variety of areas most of us struggle with at some point. Simplifying a broad spectrum of dynamics that influence our emotional reactivity, Aikido has the potential to show that at the root of all conflict is our quest for safety. The way that it reveals this is by taking us on a journey towards developing an embodied knowledge that who we think we are right now is only a partial truth.

Over time, as we continue to practice being in a body that flinches less and opens up more in the spaces we inhabit, the idea of a fixed sense of self gets increasingly left behind. It is this shift, coupled with the fact that it is facilitated in partnership with others, that enables us to transcend the urge to project our fears onto others. It is precisely in the moments where two parties project their fears onto the other, believing their own versions of the truth to the exclusion of the other, that they fight. At an abstract level it is a fight to prevent their truth from being obliterated or consumed by the others. At a more physical level it is a fight provoked by a sense of scarcity of one kind or another; in the modern age we are fortunate not to have to face real scarcity of resources that often, therefore most examples of conflict arise from a scarcity of feeling safe in the body; de-oxygenation from breathing shallowly in a state of fright is a literal example of scarcity in the body and it has direct implications for how we make sense of things both emotionally and mentally. Our decision-making capabilities are either enhanced or degraded by the state of our wellbeing; stress has a direct impact on our ability to gauge the consequences of our actions and often leads to actions that limit our possibilities for living a better life.

These moments of conflict are at their most threateningly real when both sides are at the stage of their development where they have invested more in their sense of identity than they have in their strategies for how to live a better life with others. However, it is precisely these moments of conflict that are the exact moments when we are closest to a reconciliation of differences, towards a greater whole. If we can find a way to have open hearts, with the intent to make space for the other, in a dance of movement and mindful partnership, then we are provided with an opportunity to ‘get over ourselves.’ Training together in Aikido the practitioner, or Aikidoka, can gain an appreciation of the harmony of all things that awaits our calm attention. When in the deep flow of a training session our bodies experience living reality as an ongoing process, flowing change into fusion and fusion into change as we become more aware of the interconnected nature of all things. But therein lies the core problem of the human condition: We are profoundly unaware of the inherently interconnected nature of things. This is, and has always been, a very special kind of ‘hidden’ knowledge, known as esoteric, sapiential or ‘initiated’ knowledge; only available to those who are fearless enough to surrender themselves to a greater truth. Aikido has the potential to offer access to this ‘hidden’ knowledge through a lifetime of practice in a community of practitioners who all go through similar stages of confronting others in practice to realise they were only ever confronting themselves.

Throughout the course of our lives we will go through phases or stages where our world seems to be coming apart at the seams, which can be particularly surprising at times when we felt we were ‘doing well’ or ‘really getting somewhere.’ The truth of this phenomenon of human experience is that it is developmental, and the parts of our lives where we are really developing generally feel confusing. Ken Wilber (2000) discusses the concept of fulcrums in *Integral Psychology* as axial points along our developmental journey. His description is also a useful one for the journey one undertakes in Aikido; from an embodied point of view Aikido was seen as very supportive of ‘vertical literacy’ both by Tony Buzan the chief exponent of mind maps, and George Leonard, one of the early developers of integral transformative practice.

> Each time the self (the proximate self) encounters a new level in the Great Nest, it first *identifies* with it and consolidates it; then disidentifies with it (*transcends* it, de-embeds from

> it); and then includes and *integrates* it from the next higher level. (Wilber, 2000, p. 35. Italics in the original)

This is how learning, or most forms of growth occur, i.e. it is the tears in our consciousness that allow more information to get in, and when it does it starts the process of integration towards a greater whole. From this perspective we can see what at least three of the things are that Aikido is trying to tell us:

> One, conflict is neither bad nor good, it simply is; two, conflict is absolutely necessary to almost every life process; three, people need training in how to respond effectively and appropriately to conflict situations. (Dobson & Miller, 1992, p. xii)

Creating Space for Change

Another core element within Aikido is the concept of Ukemi (see Figure 1), which is the process of taking a controlled fall, known as a break-fall, so that we are able to 'survive' attacks that we have not been able to fully avoid. The key to Ukemi in the deeper conception of Aikido is that it enables us to keep the space open for further understanding, as we do not dig in and engage in a game of attrition. Rather we bend and move with the energy and use the space around us to safely fall out of the way, quickly regaining our balance and finding a safe distance again.

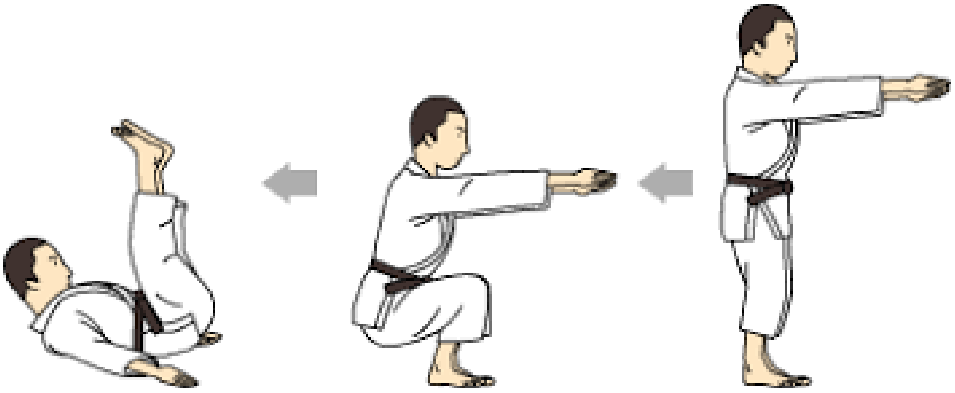

Figure 1. Ukemi illustration: backwards break-fall.

Ukemi is a form of surrender which enables the space between self and other to be respected and maintained without the corruption of violent damage. On our lifelong journey towards a more connected relationship to all things we experience what could be described as 'mini deaths.' This is where our old selves die a little bit in order to integrate new truths (see Figure 2). In 'Tobi Ukemi' the Aikidoka must literally get over themselves in a high flip to avoid a potentially broken wrist (at the minimum if it were a real conflict). The experience of learning to do this is like coming to the edge of a cliff and experiencing the very end of everything we know as we take a leap into nothing. The edge or end of what we know can feel like the edge or end of all things, and that end includes the end of ourselves. In Aikido we regularly go over that edge, into a space that is beyond who we were before.

The more that we practice literal and metaphorical Ukemi, the more we realise that we can 'survive' further encounters with new truths; we become both more than what we were, and the truth that we integrate within our being. Both ourselves and the world have changed in the process of integrating new feelings and insights. One cannot help but draw a relationship here to what it is like to actively pursue 'the good the beautiful and the true' in a world filled with so much miscommunication and confusion, wherein fear is the natural reaction to 'the unknown;' or the merely 'poorly understood.' The stages of being on our developmental journey are marked out by moments of surrender, so that we can access the greater space and truth that awaits us just beyond our current moment.

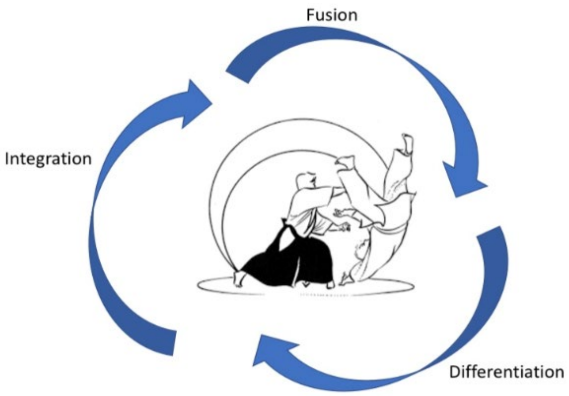

Figure 2. Tobi Ukemi (high breakfall) and overlay of developmental cycle.

Aikido has, at its core, a deep relationship to space and the moment before any action, a moment in which there are myriad possibilities. It is precisely this space that is essential for anything to express its energy in the moment. If we give something the space it needs in order to be seen and understood we can better appreciate its nature; increasing our chances of placing it in a broader, more complete context. One could argue that for an integral vision to emerge, there must be enough space in mind for myriad truths to find their place in a more holistic model of the world. In Aikido these concepts are brought to life within the body, both in motion and in stillness through years of methodical practice.

This practice begins (and ends) with a short meditation called Mokuso which has the purpose of helping us to access a state of awareness where we allow our attention to more fully inhabit our space, known as Mushin Mugamae; a state of pure bright awareness with no intent in any direction; neither towards nor, away from anything. We begin our movement from a state of readiness which has emerged from the state of no intention, known as Shizentai; this state has us ready to move in any direction but not yet committed to any direction.

> With a still heart one can access the wonders of nature and by suppressing action one can still the gods of change. (Tomiki, 1958, in Allbright, p. 41)

A vital aspect of our journey in Aikido is to become increasingly aware of the gestalt of the room in which we train; this is tested during practice and furthermore when we are graded at a senior level. With this awareness we then move, in partnership with our fellow Aikidoka; deeply respecting our relationship to our partner and the many others around us. Even when training to respond to attacks we are constantly judging, feeling, sensing the distance between us and the other and then moving to a different vantage point at the moment of attack. This is known as Tai Sabaki

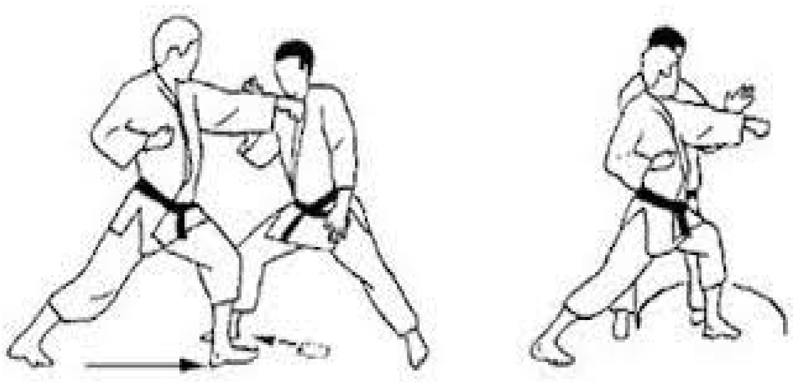

Figure 3. Tai Sabaki: coming off the line (left) and using a circular motion for redirection (right)

(see Figure 3) and can be translated as body avoidance/movement. Rather than opposing the incoming 'communication' we move off the line to an angle (or vector); primarily so we are not harmed but also so that we can respond with the least harm possible to the attacker. The problem with most conflict is that people stay on the line, in front of the other, in effect 'opposing' the other; taking up the position of opposition immediately brings with it predictable counter-productive outcomes; this is why Aikido is less about competition to win against others, and more about co-development so that we can win together.

It is very common in Aikido to allow the force of a blow to come past us and then redirect it in a circular motion to allow the energy to play itself out. This gives the communicator the chance to play out their message without the worst kinds of conflict emerging i.e. where one or both parties are seriously harmed. This kind of mindful movement is very much like when we ask questions with the intent to understand rather than needing first to be understood. We keep asking questions until the thing that has created the energy in the moment has been exhausted, and we find ourselves at the end of a process of learning; one of many cycles of fusion, and then exploration that leads to further differentiation and integration. In Japanese they have a phrase you will often hear when training which is Mou Ikkai, which translates simply as 'and again' or 'repeat' but the difference is that it comes completely without judgement and with the expectation that anything that is worth doing is worth doing many many times in order to achieve competency. If you fail the answer is mou ikkai, and if you succeed? Mou ikkai!

The Body is Our Deepest Frame of Reference

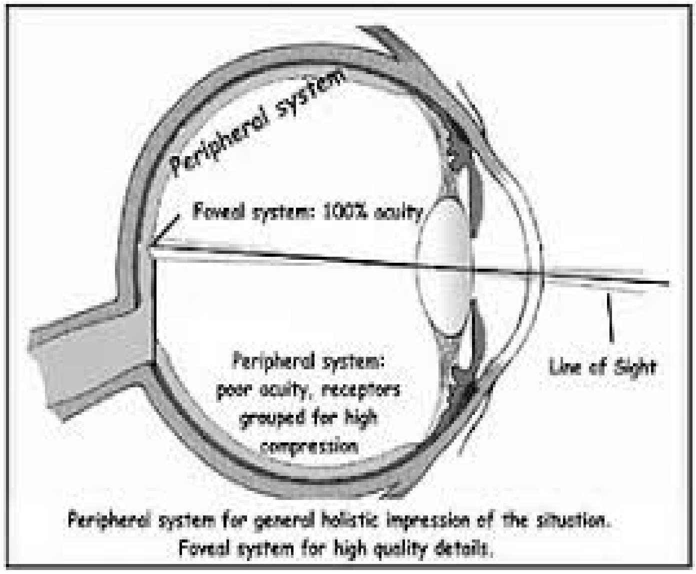
All of this is very intellectual, and as Aikido is primarily an embodied practice it is also important to take up an embodied viewpoint here. We mostly learn Aikido without talking; some dojos (training studios) are quite rigid about this for a variety of reasons. One very good reason is that the new information we are trying to learn cannot immediately be processed until we have first learned the frame of reference that we need in order to relate to it: to become it. The frame of reference we first acquire is within our bodies, and it implants a deeper sense of balance and its vital importance within our psyche.

Aikido, from an embodied perspective, could be seen as a practice of stealing the balance of others, known as Kuzushi, whilst also being totally prepared to have yours stolen. Interestingly, another definition of Kuzushi is 'mind-steal,' wherein an opponent has a piece of their mind or attention stolen, to the advantage of the one who can leverage the opportunity that it creates. The problem that faces almost all new beginners of Aikido is that they arrive on the training mat already off balance in their bodies. This basic state of being off balance in their bodies makes the initial learning process a steep one, with very little in terms of 'takeaways' to show for it. The application in the everyday world from this ongoing adaptation to becoming more balanced in the body and mind, is commensurate with becoming increasingly ok with having this balance temporarily stolen in the body without it putting you mentally off balance.

A full-blooded Aikido session for an active participant will see a person doing hundreds of breakfalls until being on the floor is just as valid a part of the learning experience as being upright. An experienced Aikidoka knows that whether they are giving or receiving techniques the best lessons are the ones that challenge us. As a receiver of a technique we are the one who surrenders and takes a fall. This role has less to remember but it is more physically demanding. As the giver we carry the responsibility for remembering and performing a technique both accurately and safely; either can be highly challenging at different stages of development. Aikido is an embodied artform wherein this learning cycle of giving and receiving, of surrender and agency mirrors a variety of patterns of experience that we struggle with in everyday life. Where Aikido really excels at getting to the root of what blocks the learning cycle is its ability to teach us through our bodies how to escape the myriad double binds that stop us in our tracks, often leading to entrenchment and resistance to new information., For example, we are hard wired to stand upright and to avoid falling and yet failure and making mistakes are fundamental to a healthy and productive learning cycle. We are geared to move forwards, rather like an automatic car left in drive mode, and therefore we don't handle going backwards well as it feels counterproductive to our core sense of purpose and direction. Ukemi acts like a somatic antidote to this dilemma, quelling the all too human aversion to falling over and the more general fear of failure, particularly when either are witnessed by others.

Breath, Vision and Our Dynamic Potential

Another confounding factor for the beginner in Aikido is that most of us live primarily in our heads, breathe shallowly in our chests and have very little natural peripheral awareness. We're also scared stiff of falling over, which is a metaphor that proves quite costly when we do fall as our bodies suffer more from being rigid than if they were relaxed. All of these bodily impediments are vitally important in the context of our greater developmental journey as they relate to our ability to be vulnerable to all of the new information that we will need to process on the route to becoming our increasingly inclusive and integrative selves. As we develop the ability to breathe more fully throughout all of our movements, and in advanced stages to enhance our movements, we find



Peripheral system
Foveal system: 100% acuity
Peripheral system:
poor acuity, receptors
grouped for high
compression
Line of Sight
Peripheral system for general holistic impression of the situation.
Foveal system for high quality details.

Figure 4. Peripheral vision system highlights how 'sight received' information flows into the brain either in a narrow stream (foveal) or a broad stream (peripheral).

ourselves more able to handle obstacles outside of the training space. Access to more information and a wider array of options become available to us as our peripheral awareness (see Figure 4) becomes an integral facility supporting how we process our reality; leading to more information being processed from within a broader context.

Frame of Reference Equals Frame of Relevance

It is precisely this increased capacity, to process more information from an increasingly broader context, that underpins both continuous adult development and the inoculation against the need for violent conflict. The counterpoint that Aikido works against is the 'tunnel' vision effect that arises from entering a fight or flight state. Tunnel vision is similar to foveal vision, which is at the acute end of our ability focus our eyesight and is ideal for focusing on what is immediately in front of us, however it is often to the cost of broader context or new information. Coupled with being in an unresourceful state this is a potent recipe for various levels of conflict. We all have blind-spots, areas we overlook, or 'things that are missing from our frame of reference, therefore they are not in our frame of relevance.'

Aikido is just one way of supporting our capacity to expose these blind spots to increased awareness, however as an embodied methodology it is a valuable factor in a broader integrated approach alongside more cognitive practices.

> Ultimately, physical, psychological and spiritual mastery are one and the same. The egoless self is open, flexible, supple, fluid, and dynamic on body, mind and spirit. Being egoless, the self identifies with all things and all people, seeing them not from its self-centred perspective but from their own respective centres. In a circle of limitless circumference every point becomes the centre of the universe. (Ueshiba, 1984, p. 9).

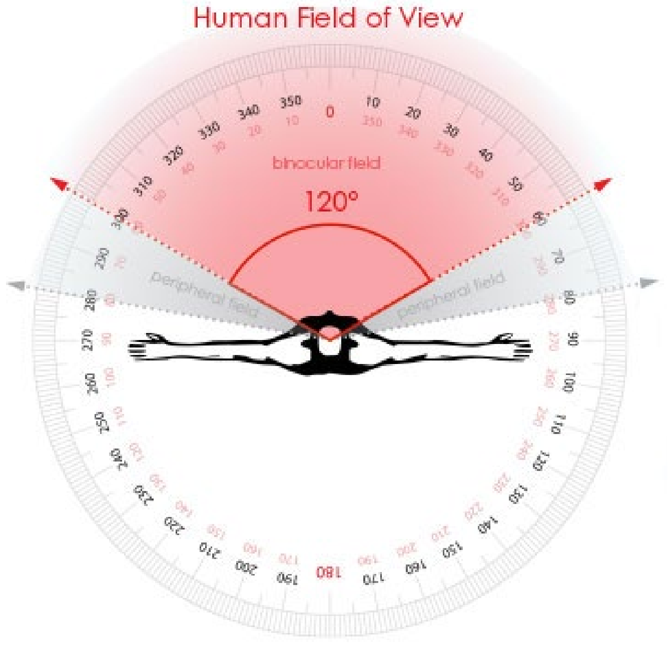


Figure 5. This illustration of the 'Human field of view' highlights our true context as beings that live in a 360 degree position in space.

As we adapt to living in a body that is comfortable shifting within any permutation of a 360 degree position in space (see Figure 5) we increasingly find ourselves able to take different perspectives and vitally, get out of our own way so that we can see what something is from someone else's perspective and not just from our own. The net effect is a kind of 'switching off' of the smaller (identity) self and an increasing of our fullest potential self (spirit), unrestricted by fears, planning or strategizing. From here there is receptiveness, flexibility, speed and fearless engagement. This quote from Professor Kenji Tomiki beautifully sums up Aikido with Mushin Mugamae at its core:

> Non-conscious action stemming from a neutral physical posture (in other words, neither aggressive nor submissive – mu gamae), executed without emotion or prejudgment (mu shin). (Allbright, 2002, p. 41)

A Personal Reflection

Over time, I have been fortunate to experience glimmers of these kinds of realisations. I increasingly experience states of a kind of activated or applied openness where my model of the world is more readily open to being expanded. Even in the face of facts that I would quite often prefer not to be true, the benefits from accepting them continue to outweigh the initial struggle to relate to them and eventually integrating them within a more holistic model of reality. The opportunity to pursue my master's degree was a classic example of this. I was working on having a workshop certified for CPD credits to be delivered as an executive training and had it failed by the supervisor. That same supervisor liked the way that I took the feedback onboard and commented that the work I had put into creating the course said to her that I had what it took to make an application for higher learning for master's course in applied coaching. I took the hit of the rejection as a gift and flowed with the direction of the energy it had to give. The outcome was to change my life by giving me a space in which to pursue my core interests at an advanced academic level. If I had become fixated with the failure to have my course certified I would not only have failed to move forwards, there's a strong possibly that I would have gone backwards, with no profit (learning) to show for it.

The final core concept I would like to share is more generally a Japanese one, but it is quite common to hear it being said in Aikido: Ganbatte. This word means to really go for it, and to do your best. It is said with a passionate energy and it is a core aspect of the Japanese psyche that they really want you give it your all, even if they might have to work harder because of it.

Ganbatte.

Ken Wilber's Problematic Relationship to Science

Frank Visser[1]

Abstract: Ken Wilber has argued for a spiritual view of evolution. To make his case he has defended three knowledge claims: (1) current science fails to explain major transformations in evolution, (2) some scientific views seem to support his view that the cosmos is inherently creative, and (3) his own theory of evolution is "the only theory that can actually explain the mysteries of evolution." The validity of these three claims is questioned by the argument that a more believable integration of evolutionary theory within integral theory is called for. This requires both an openness to criticism and more solid expertise in this specific field of science. Thus far, both of these features have been lacking within both Wilber's writings and the integral community.

Keywords: Eros, evolution, evolutionary science, extended synthesis, integral theory, modern synthesis.

Introduction

Throughout his many works, Ken Wilber has shown an ambiguous attitude towards science, and especially evolutionary science. Even though the concept of evolution has been central to his entire work spanning four decades, his engagement with evolutionary theory has been minimal. He has often argued science can't explain some forms of complexity. He has suggested his ideas are like those of some famous scientists, seeming to suggest they implicitly support his ideas. At the same time, he has explicitly denied that these scientists would accept his specific idea of evolution as Spirit-in-action, metaphorically pictured as Eros-in-the-Kosmos. And finally, he has claimed to have "the only theory that can actually explain the mysteries of evolution" (Wilber, 2017, p. 14), even though his mystical notion about Eros doesn't qualify as a scientific theory. In sum, the interface of integral theory with evolutionary science needs much more thoughtful consideration than it has received until now.

In 2010 I presented the paper "The 'Spirit of Evolution' Reconsidered" at the Integral Theory Conference, where it received an honorary mention in the category of constructive criticism. It reviewed in chronological order the most salient written and online statements Wilber has made about evolution and evolutionary theory (Visser, 2010). Over the years I have offered the more critical reviews in dozens of essays on Integral World (Visser, 2008). Here, I propose a more systematic and analytical treatment of the areas where Wilber and evolutionary science meet – or don't meet.

---

[1] **Frank Visser** (b. 1958) is a long-time student of the work of Ken Wilber and author of *Ken Wilber: Thought as Passion* (SUNY Press, 2003). He is webmaster of Integral World (www.integralworld.net), an online independent forum for a critical discussion of the integral philosophy of Ken Wilber. Originally a psychologist of religion who graduated on mysticism, he turned to book publishing and website maintenance for a living. He has presented papers at several integral conferences in the US and Europe and lives in Amsterdam.

SOME RIGHTS RESERVED

Wilber has given four reasons for taking a spiritual perspective on evolution. In his recent *The Religion of Tomorrow* he argued, among other things:

> Rational reasons to believe in this miraculous spiritual dimension to Reality include the following: (a) the "creative advance into novelty" that is demonstrated by evolution itself and is inexplicable by mere "chance mutation" (the evolution from strings to quarks to subatomic particles to atoms to small molecules to massively interconnected molecules to asexual cells and early organisms – just for starters – is an awful lot of evolution in a universe that is supposed to be "running down" but can easily be seen as yet more evidence of creative Eros or Spirit-in-action, "a self-organizing self-transcendent drive," as Erich Jantsch put it). (Wilber, 2017, p. 498)

The other three areas involve the interconnectedness of things and events, the presence of consciousness and the evidence from meditation. This quote reveals a number of problematic claims. First, the grand sequence from sub-atomic particles to complex biological organisms is taken as *prima facie* evidence for a Spirit behind everything. Second, doubt is cast on the commonly accepted view in science that the second law of thermodynamics, according to which the universe is "running down" holds sway, apparently in contradiction to the increase of complexity Wilber refers to. And third, this cosmic process is explained, quoting complexity scientist Jantsch, by a generic "drive" towards self-organization and self-transcendence.

In my view, the growth towards complexity can be explained more fruitfully by closely paying attention to what science has to say about each of these transformations. Chance is only one of the many factors involved. Further, this growth towards complexity does not violate the second law but is paradoxically powered by it through the energy flows it continuously generates. And finally, postulating a generic drive towards complexity (or behind biological evolution) leads to more questions than it answers. Why, for example, would that drive work well on Earth but not on the Moon or Pluto, if Eros is a cosmic phenomenon? And why, for that matter, did it take billions of years before even on Earth complex life arose? Science provides more believable explanations for these processes.

We can contrast a religious with a scientific view of reality like this. In the religious view, taken by Wilber, one feels overwhelmed by the complexity of nature and invokes a metaphysical principle (Spirit) to explain it all. Before exploring reality, one already knows the final answer. Science comes down from that "view from 40.000 feet" and breaks up this problem in more manageable chunks. It does not pretend to have final answers but makes daily progress in solving these piecemeal problems. Invoking Spirit to solve problems of science is a non-starter, a question-begging strategy, the "God of the gaps." When one argues for Spirit, it is important to find areas where science supposedly fails, as much as areas where science can be included. Even a creationist will accept that minor variations are possible during evolution. It is major transformations that are usually seen as problematic within the current status of science. This is Wilber's stance as well (Wilber, 1995, p. 10, 492).

On many occasions Wilber has expressed doubts about the ability of science to solve the mysteries of evolution – so that it needs to be complemented by a spiritual perspective. Here's an example from a recent Integral Life video (Wilber & De Vos, 2019):

> One of the most *boring* criticisms I have received over the years is that my theory doesn't fit the modern theory of evolution. And that's right! The modern theory of evolution is *catastrophically* incomplete!

A strong statement such as this leaves me to wonder, if, to make this field of evolutionary science "more complete," we are supposed to add Spirit to our worldview, or if we rather should really investigate what current evolutionary theory entails. A similarly strong statement about the incompleteness of science was made in a blog post by Wilber in which he responded to criticism about this understanding of evolution (Wilber, 2006b):

> Do I think Mayr or Dawkins or Lewontin or Kauffman believe in telos or Eros that is Spiritual in any way? Absolutely not. Virtually all mainstream theorists embrace *scientific materialism*.

This, again, makes me wonder, if Wilber's view of evolution is in fact not supported by science at all. Yet on occasion, as I will show, he claims support from famous scientists. However, in general one cannot claim support from thinkers that do not share one's particular views. Personally, I would worry when the view of evolution I hold is not supported by science, but Wilber apparently thinks otherwise. He indicates his reliance on other ways of knowing, based on his own mystical readings or meditative experiences (generally phrased by him as the "Eye of Spirit").

But in general, when one invokes an extra-scientific principle to explain the complexities of nature, one surely has the burden of proof to show that this explanation really clarifies things. As is the case with the God of the creationists, this is fundamentally impossible. Wilber's spiritual-mystical views on evolution suffer from the same fundamental drawbacks, in my opinion.

To see more clearly where Wilber and science meet, or part ways, we need to see what Wilber's view of evolution actually consists of. Then we need to see if evolutionary science speaks with a single voice about evolution or many different (and sometimes conflicting) voices. And finally, we need to see if there is common ground between these two areas.

Ken Wilber's View of Evolution

Where to begin? Why not at the beginning? In his first book, *The Spectrum of Consciousness*, Wilber (1977) pictured the cosmic process (following Coomaraswamy) as divided in two phases: evolution, or the movement from Spirit to *maya* (matter), and involution, or the opposite and subsequent movement from *maya* to Spirit. In later works he reversed these terms (following Sri Aurobindo), with involution being the prior movement from Spirit to maya and evolution being the opposite and subsequent movement from *maya* to Spirit. (Wilber, 1993, p. xviii-xix) However, the basic abstract scheme remains the same: All natural processes come from Spirit and return to it, whichever name we give to its phases.

Spirit therefore plays a crucial role in evolution as Wilber understands it. This is clear from another early work, *Eye to Eye,* in which he states: "The strict theory of natural selection suffers from not acknowledging the role played by Spirit in evolution" (1983, p. 205). Further, the subtitle of *Sex, Ecology, Spirituality* (1995), his major academic work, is "The Spirit of Evolution," and in *A Brief History of Everything* (1996), a more popular version of this main work, Part One was specifically called "Spirit-in-Action." One can even say he believes in a certain view of evolution because he believes in the doctrine of involution.

This active view of Spirit differentiated the neo-perennial philosophy from its predecessor the Perennial Philosophy, according to Wilber. Where Spirit was traditionally depicted as the passive Ground of Being, without any clear notion of evolution, in this more recent formulation Spirit is seen as both passive and active at the same time: passive-transcendent as World Ground and active-immanent as World Process. This Neo-Perennialist view was rather recent, "no more than a few hundred years old" and its precise origin is "almost impossible to pinpoint exactly." It started with Hegel and Schelling, was taken up by Spencer and "applied to biology" by Darwin, before reappearing in Sri Aurobindo and Teilhard de Chardin, in Wilber's reading of the history of evolutionary thought (1997, p. 62-63).

In Wilber's reading of the evolutionary literature, Charles Darwin didn't do much more than "dutifully and drudgingly" (Wilber's words) accumulate evidence for a view of evolution that was already "in the air" (Wilber, 1995, p. 491). What Wilber failed to realize, is that Darwin fundamentally *broke* with the prevailing notions about evolution, in a way that was shocking to many of his contemporaries, even to those who accepted the theory of natural selection. Darwin replaced the concept of transformation or transmutation, as evolution was called in those days, by the theory of variation and selection (Visser, 2019d). And where Wilber (1995, p. 491) concludes in *Sex, Ecology, Spirituality* that Darwin's lasting contribution was to obscure "for over a century" a spiritual view of evolution (driven by Eros or Spirit), for science his contribution was taken to be an enormous clarification of the evolutionary process (Visser 2019d). Wilber's concept of evolution is fundamentally at odds with that of science. It is here that Wilber's scholarship is most wanting and in need of a substantial correction.

Wilber's highly esoteric-idealistic view of evolution gets brief mention in the historical overviews of the idea of evolution. For example, Bowler (2009, p. 209), in his *Evolution: The History of An Idea,* does mention Goethe, Hegel, Fichte and Schelling in a brief paragraph on Idealism and Romanticism, and their reaction to Enlightenment materialism, in which they wanted to see "spirit as an active force imposing its will on nature to create order and purpose." But nothing like the elaborate esoteric doctrines of involution and evolution can be found in the Western philosophical literature.

A more likely source therefore, is the Western-esoteric Theosophical tradition, which started in 1875 with H.P. Blavatsky and whose magnum opus *The Secret Doctrine* (1888) contained not only elaborate details about involution and evolution, but also dozens of references to Darwin. According to Indian scholar Meera Nanda (2010, p. 284) all these Eastern-esoteric philosophers are "Blavatsky's Children" (Visser, 2019c). She writes: "The entire repertoire of intellectual arguments used to dress up traditional Hindu cosmology in the scientistic costume of progressive evolutionism was created and popularized originally by Madame Blavatsky and her fellow Theosophists" (Nanda, (2010, p. 284). Theosophy revitalized Indian philosophy, but introduced ideas of its own, one of which were the elaborate cycles of involution and evolution. Meera emphasizes specifically that these Hindu doctrines are incompatible with Western science.

> What immediately stands out about these theories is how deeply and fundamentally they contradict Darwin. While Darwinian theory explains [the] evolution of species by descent from a common ancestor by genetic modification, Hindu teachings assume spirit or consciousness to be the primary force of evolution. Does it not follow, therefore, that one can't believe in the Hindu view of evolution, and in the same breath claim to be in accord with [the] scientific – i.e., Darwinian – understanding of evolution? (Nanda, 2010, p. 282)

This points to a fundamental theoretical difference Wilber tends to gloss over in his dealings with evolution. Integrating the Darwinian view of evolution has consequences for any spiritual view of evolution.

Of course, some contemporary thinkers have tried to forge an integration between these two opposing views, usually called theistic evolution, in the sense that evolution is God's way of creation, or that God fine-tuned the original conditions under which evolution could subsequently take off (Lazlo, quoted in Visser, 2014a). I have called this "the God of the Knobs" (Visser, 2019b). But I find these forms of synthesis or integration hardly convincing. They are parasitic on the scientific view because they never specify the added value of introducing Spirit. And what empirical data are proof for God's existence? This is the major weakness of Wilber's view of evolution: if there is such a pervasive cosmic force operative in evolution, as he claims, how could that possibly work in practice and be detected?

To repeat, traditional doctrines of evolution were "transformational" (or "transmutational" as it was expressed in the nineteenth century) to use Ernst Mayr's (2001) terminology, whereas Darwin's proposed a "variational" model of evolution. In the traditional view, species morphed into other species by a mysterious process of transformation or transmutation, whereas Darwin abolished such a notion in favor of variation, selection, and inheritance. Wilber is fond of using the terms "transcend-and-include" when dealing with evolutionary processes, which are supposed to be driven by Eros, a Whiteheadian "creative advance into novelty" or an "extraordinary power." In a video on evolution Wilber (2014) claimed:

> This seems to be the general overall thrust of evolution – and one of the things that is certain about it – is that it won't give up. It simply is there, with an extraordinary power, in the entire cosmos.

Scientists don't think in these generic and generalized terms about evolution at all. They want to precisely understand under what conditions complexity may or may not emerge.

There are only two basic options here, in my opinion. Either there is such a pervasive "drive" towards complexity in the cosmos, or there is not. If there *is*, one has to explain why, if we take our solar system as an example of a self-contained energetic unit, life seems to be so rare – as far as we can tell. Life on earth seems to be the exception to the rule, instead of the rule itself. But if there is *no* such cosmic and pervasive drive towards complexity, the task is to explain why there is life *at all* in our solar system. Science understandably points to the specific conditions that exist on Earth – the so-called "Goldilocks conditions" of the habitable zone in which our planet exists (Christian, 2018). The fact that life may exist outside of our solar system, and may even be abundant, does not change that observation. Invoking metaphysical principles should really be our last resort – if at all.

Incidentally, this does not mean that the scientific theory of evolution doesn't accept the notion of progress, as is often assumed mostly because of Stephen Jay Gould's influential anti-progress arguments (Gould, 2002). However, both Ernst Mayr (2001) and Richard Dawkins (2003) have argued, persuasively, that natural selection was *bound* to lead to progress, under certain conditions, and in the restricted sense as being better adapted to the environment. What is not accepted by science is a general progressive movement in all departments of nature, least of all driven by an inherent force or pressure, let alone one of a spiritual or divine nature, as Wilber proposes. This latter conviction remains, in the words of Dawkins (2017, p. 124), a mystical doctrine which is "not really a theory at all, and I shall not bother to discuss it. It is obviously mystical and does not explain anything that it doesn't assume to start with." I agree with this assessment of the theoretical emptiness of these mystical notions. Wilber's notion of a Spirit-driven evolution (which can hardly be called a "theory") suffers from the same defect.

Does Wilber in fact *have* a proper theory of evolution? In his main work Sex, *Ecology, Spirituality* Wilber (1995, p. 35-78) has fleshed out his "Twenty Tenets," which he defined as "the 'laws' or 'patterns' or 'tendencies' or 'habits'" that "all known holons seem to have in common," (p. 34). Remarkably, in this long section those thinkers that get included are philosophers, psychologists, social scientists or complexity scientists, such as Whitehead, Derrida, Foucault, Freud, Marx, chaos theorists – but most notably absent are those who should be consulted first when it comes to evolution: evolutionary theorists. In fact, these Tenets are highly abstract descriptions, not causal explanations. As one example, tenet 3 reads "Holons emerge," which is to say that atoms give rise to molecules, as molecules give rise to cells, etcetera. That may be true at an abstract-descriptive level but doesn't contribute to our understanding of *how* exactly molecules and cells emerge from simpler holons. These processes are usually well understood by science and are non-mysterious.

In his more popular books or videos, Wilber has used a rather colloquial style of presentation to convey his understanding of evolution. Most of these dealings with modern evolutionary thought have been rather critical about mutation/variation and natural selection theory (Wilber restricts himself usually to neo-Darwinism). He usually questions that science can explain a certain form of complexity (be it human eyes, bird's wings, the immune system, regeneration, morphogenesis or speciation) without in any way engaging the relevant evolutionary research literature. More often than not, this criticism is couched in graphic and sarcastic statements, meant to cast doubt on the scientific, neo-Darwinian understanding of evolution. Here's a typical example taken from a video about Integral Buddhism.

> To get one species from another requires several mutations. It's well-known that the vast majority of mutations are lethal, so we would have to have several extremely unlikely mutations all occurring at once in the same animal. But even more unbelievable, the exact same number and type of mutations would have to occur in another animal of the opposite sex, in order for them to procreate and pass on the new mutations. And even more unbelievable yet, these two would have to find each other – what if one is in Siberia and the other in Mexico? The odds of all of those happening is basically zero. (Wilber, 2014)

Science, however, explains speciation by populations being split in two parts, so the problem of its members being in two countries far apart simply does not arise (Coyne & Orr, 2004). How mutations spread within populations is well understood by the modern synthesis. Again, Wilber's understanding of the principles of evolution is inadequate and at variance with science. What does he actually have in mind, that Eros is tweaking genes? That Spirit is the Great Mutator? He does not tell us.

On more than one occasion, Wilber has pointed to the literature of intelligent design, which, he believes has correctly identified the shortcomings of neo-Darwinism, even though he disagrees with their alternative solution (of the Christian God). For example, in a footnote of *Integral Spirituality* he states,

> I am no fan of intelligent design either, which is just Creation Science in drag. But you don't need an intelligent designer to realize that evolution seems to involve some "creative allure," or what Whitehead called "the creative advance into novelty." That drive – Eros by any other name – seems a perfectly realistic conclusion, given the facts of evolution as we know them. Let's just say there is plenty of room for a Kosmos of Eros. (Wilber, 2007a, p. 236n.)

What "facts of evolution" has Wilber taken into consideration, one wonders? Wilber's "integral design," as we can call it (Visser, 2009), suffers in my opinion from the same defects as intelligent design proper: it doesn't have a *positive* theory of evolution of its own. Apart from a generic "drive towards self-organization" no further details are provided. All it can do is cast doubt on science and its supposed shortcomings, but it cannot, by definition, get explicit about the ways of working of the divine Eros or Spirit.

As Shanks (2004) formulated it in his critique of intelligent design "theory": creationism (or intelligent design) cannot answer the crucial questions about the What, Who, How, When and Why of evolution. Wilber may not be a typical creationist (Visser, 2019), but he can with some justification be called a "creativist" (Visser, 2011). In Whiteheadian style, Wilber relates all evolutionary novelty to the "creativity" inherently present in the universe. This primordial creativity cannot be explained any further, other than identifying it as the "action" of the divine Spirit. As we will see, there are other, more believable ways to conceptualize the creativity of the cosmos.

A different way to contextualize Wilber's take on evolution is found in the magazine article "The Real Evolution Debate" (2007), which was published in *What Is Enlightenment?*, a Andrew Cohen related publication which served as medium for Wilber's ideas for many years. In it, no less than twelve approaches to evolution are portrayed, six from a material-scientific and six from a spiritual-religious perspective.

Table 1. Scientific and Spiritual Approaches to Evolution

SCIENTIFIC	SPIRITUAL
1. Neo-Darwinists	7. Intelligent Designers
2. Progressive Darwinists	8. Theistic Evolutionists
3. Collectivists	9. Esoteric Evolutionists
4. Complexity Theorists	10. Process Philosophers
5. Directionalists	11. Conscious Evolutionists
6. Transhumanists	12. Integralists

It is argued by the anonymous author(s) that the evolutionary landscape is much more varied than the usual “Darwin vs. Design” dilemma, which dominates our public discourse. Wilber's integral philosophy, listed as the final and most comprehensive approach, is described as follows,

> "The integralist's goal is not so much a new theory of evolution but a larger perspective that can effectively integrate disparate existing theories, both spiritual and scientific, into a coherent picture of the entire evolutionary process. More than synthesizers, they offer a sort of radically inclusive meta-theory, one that sees truth everywhere – from the gene-centered focus of the Neo-Darwinists to the mathematical insight of the Complexity Theorists to the creativity of the Process Philosophers – but attempts to provide a larger context that allows us to see the relationships between these many evolutionary perspectives… Like the Conscious Evolutionists and the Process Philosophers, the Integralists are reaching for a higher synthesis and a deeper integration between science and spirit." (p. 100).

Be that as it may, in my opinion the two basic options still remain: evolution is seen as either *unguided* (or naturalistic) or it is seen as *guided* (by whatever divine Principle, Process or Person). Wilber's Eros-in-the-Kosmos is such a transcendental Principle, which places him squarely in the religious-spiritual-mystical camp.

This raises the pertinent question: what is the added value of that "larger perspective" and "coherent picture" in terms of understanding evolutionary processes? For example, does a Whiteheadian "creative advance into novelty" qualify as a theory? Or does it provide any new understanding? Is it an improvement on what science has to offer, as Wilber claims? Can a meta-theory actually have any bearing at all on scientific problems? Wilber suggests a positive answer to this question by introducing the notion of Eros when discussing the evolution of eyes and wings, or other biological phenomena, but it is questionable.

Wilber claims to transcend-and-include science in his integral philosophy, but this leads to problems: evolution is either guided or unguided. Tertium non datur. Or put differently in more modern terms: you can't have it both ways. Species are either created or evolved. And if science is included to some extent by an integral philosophy, to what extent is it included? And more importantly: when is it transcended? Wilber does not provide any specifics here.

In summary, by introducing Spirit into the evolutionary equation Wilber doesn't clarify any single empirical evolutionary problem. He does on occasion refer to some areas of science, most notably complexity and chaos science, that seem to point into the direction of a creative cosmos, but we should keep in mind this in no way implies automatically there is a Spirit behind everything we see in nature. His attempts to cast doubt on the ability of science to explain these natural phenomena have not been very convincing to me, in part because his penchant for caricature and dismissive humor have not helped create an atmosphere for serious reflection.

What Does Science Say About Evolution?

Turning now to science itself, it should immediately be obvious there is not one single scientific theory about evolution – or about anything else within the province of scientific study, for that matter. Instead, there are various schools of thought, which debate intensely about the mechanisms of evolution, and more specifically the relative importance of natural selection. Most, if not all, however, subscribe to the Darwinian thesis that we do not need to invoke spiritual forces to explain the diversity and complexity of nature – nor should we.

Of these evolutionary schools, Wilber usually refers only to "neo-Darwinism," which is a label applied to the so-called modern synthesis, which took form in the early decades of the 20th century. Where Darwin postulated natural selection as the main evolutionary mechanism, though not the only one, he was in the dark about the precise workings of heredity – which made many of his contemporaries doubt the viability of this model. We would call it Evolution 1.0 these days. But when the work of Gregor Mendel was (re)discovered around 1900, and the laws of heredity were formulated, Darwin was finally vindicated (let us call it Evolution 2.0).

This "modern synthesis," a term coined by Julian Huxley (1942) in his book *Evolution: The Modern Synthesis*, became the received evolutionary science. In recent decades, however, multiple *additional* evolutionary mechanisms have been proposed and debated, to the extent that an "extended" or "post-modern synthesis" has emerged (Evolution 3.0). Many of its insights have been documented in a single book as well: *Evolution: The Extended Synthesis* (2010) by Massimo Pigliucci and Gerd B. Müller. Table 2 provides a very rough timeline:

Table 2. Three generations of evolutionary thinking

1850-1900	Charles Darwin	Evolution 1.0
1900-1950	The modern synthesis	Evolution 2.0
1950-2000	The extended synthesis	Evolution 3.0

Entire new fields of investigation have opened up this way, such as: evolutionary development or evo-devo, ecology, epigenetics and phenotypic plasticity (Pigliucci, 2007). And even then, some fields have been left out, according to Dutch biologist Gert Korthof (who owns a large online review website dealing with this Third Evolutionary Synthesis, but also a great variety of critiques of Darwinism at www.wasdarwinwrong.com). He mentions among other things: endosymbiosis, horizontal gene transfer, viral evolution, earth system science, catastrophe theory, the origin of life and astrobiology (Korthof, 2014).

Difference of opinion exists in the field about how important these theoretical additions have been ("Extended Evolutionary Synthesis," n.d.). In my opinion this is just a testimony of the progress of science resulting in a richer image of the processes of evolution. At any rate, this is a lively field of scientific research. It is also sensitive to hype and exaggerated claims, as if Darwinism has been refuted. Just claiming, as Wilber does, that "the modern theory of evolution is *catastrophically* incomplete" is irresponsible without specifying what is included or excluded in the analysis. For sure, it is widely believed these days that the modern synthesis itself was still incomplete and needs to be expanded. Such is the progress of science.

In my opinion, this debate can be structured helpfully by seeing each of these schools of evolutionary thought as addressing one or more levels of the Linnean taxonomic hierarchy (Table 3).

Table 3. Evolutionary researchers address different taxonomic levels.

Taxonomic level	Researcher	Focus of study
Life	Kauffman	Origin of cells, molecules
Domains	Woese	Origin of bacteria, archaea, eukaryotes
Kingdoms	Margulis	Origin of fungi, animals, plants
Classes	Carroll	Origin of wings, eyes, limbs
Species	Darwin	Origin of species

In true integral fashion, this prevents researchers in the various fields to argue past each other. It is also relevant for assessing Wilber's statements on evolution, especially when he claims support from any of them.

As one well-known example of mixing taxonomic levels: where Darwin studied the origin of the various animal and plant *species*, Lynn Margulis (1998) focused on the way the animal and plant *kingdoms* emerged in the first place, through endosymbiosis of single celled organisms and bacteria, an insight she derived from early Russian biologists. In that sense, she went deeper, and further back in time, than Darwin was able to do. Margulis opposed Neo-Darwinist gradualism, not by invoking Spirit, but by empirically discovering *other evolutionary mechanisms.* Later in life she argued that endosymbiosis was also the main mechanism of speciation (Margulis & Sagan, 2002). But even if occasionally the tree of life shows signs of merging instead of splitting, especially in the case of horizontal gene transfer (Sapp, 2009; Quammen, 2018), the overwhelming majority of species emerge through splitting of populations (Coyne & Orr, 2004).

As a second example, and more relevant to my analysis, Stuart Kauffman pioneered the phenomena of self-organization, especially around the origin of cellular life and even molecular structure (Kauffman, 2019). His work is not addressing the question of speciation, which remains Darwin's domain, or symbiosis, which is Margulis's territory. Wilber often refers to Kauffman as an ally in his opposition to neo-Darwinism. For example:

> I am not alone is seeing that chance and natural selection by themselves are not enough to account for the emergence that we see in evolution. Stuart Kauffman and many others have criticized mere chance and natural selection as not adequate to account for this emergence (he sees the necessity of adding self-organization). (Wilber, 2007)

In doing so he overlooks that self-organization is not primarily the mechanism that produces biological adaptations or species; it is the process that spontaneously yields (constituent parts of) cells and molecules. We shouldn't mix taxonomic levels when discussing evolution. Nor should we prematurely take the incompleteness of neo-Darwinism as proof for Spirit.

Then there are those scientists who stand closer to creationist or spiritual views of evolution, even though they still don't explicitly invoke divine influences. First there's the so-called "Third Way of Evolution" (at www.thethirdwayofevolution.com), which counts as members James A. Shapiro, Dennis Noble, Eva Jablonka, Gerd B. Müller, Eugene Koonin and many others. They argue that neo-Darwinism (or "ultra-Darwinism") overlooks important aspects of the evolutionary process. They want to steer a mid-course between creationism and neo-Darwinism. Obviously, there is considerable overlap with the extended synthesis.

The creationists proper (or their pseudo-scientific spokespersons of intelligent design) argue more explicitly for a divine hand in nature. Michael Behe's *Darwin's Black Box* (1996) – a title Wilber has recommended to his students as evidence for the supposed failures of Darwinism (Wilber, 2005) – and further works inaugurated this movement, mostly in the US. Scientists have wholesale rejected this approach because it doesn't provide any *positive* evidence for or theory of divine intervention in evolution. It can only cast doubt on the capacity of naturalistic science to explain all of its details, usually by arguing for the "irreducible complexity" of this or that biochemical process. It is telling that Wilber sees intelligent design as an ally against the "flatland" approach of neo-Darwinism, while overlooking the many *scientific* evolutionary schools critical of the modern synthesis.

I would like to highlight an aspect of the notion of design when it comes to biological complexity that is often overlooked. In the case of intelligent design, it is one thing to speculate about a cosmic Spirit which has designed biological organisms or biochemical processes, it is wholly something else to *implement* this design. It is unclear to all parties involved how this could possibly have worked. And this shortcoming applies to Wilber's Eros-theory as well. Even so, as late as Wilber's latest book *The Religion of Tomorrow* he has quoted creationist Hugh Ross (2001) to argue for the improbability of life, or a habitable planet Earth, without a divine Designer/Spirit/Eros (Wilber, 2017. p. 497-498). One may ask: what does Wilber have in mind here, that Eros/Spirit prepares a planet for us to live on?

Then again, it is sometimes suggested that a spiritual view of evolution becomes available only for highly developed researchers, who have entered post-formal stages of cognition of mystical states of consciousness. An unlikely hypothesis, as if all mystics would agree with Wilber's idiosyncratic view on evolution. And if they do not? Not enlightened enough? However, one could equally argue (playfully) that these post-modern developments in evolutionary science are already made possible by higher, post-formal forms of thought.

The first Darwinists stressed the element of competition, between separate and selfish individuals, most notably by using the term "the survival of the fittest" (a term that was coined by Herbert Spencer, not Darwin, and reluctantly used by the latter). Later theorists emphasized that cooperation is much more important (Kropotkin, Margulis, Sloan Wilson). This can be interpreted as a change from agency to communion. A truly "integral" view of evolution stresses the genealogy of all the various forms of life, first as a linear ladder but after Darwin more as a non-linear, bushy tree of life which branches out in all directions. All organisms are put in historical perspective by seeing them as descended from a last universal common ancestor (Dawkins, 2016). And to understand the recent findings of the prevalence of horizontal gene transfer even between different domains (i.e. viruses and humans) requires another mental transformation, crossing traditional boundaries between domains.

Ironically, at no point in this scheme of theoretical advancement have unspecified and unspecifiable spiritual factors been introduced. Even stronger, all these new discoveries have been made by modern empirical methods (microscopy, phylogenetics, etc.). Spiritual approaches have not contributed to our knowledge of evolution at all.

Wilber has covered very little of this evolutionary theoretical landscape in his writings, seemingly implying that one is either a neo-darwinist or a creationist. He seems to feel at home in the latter camp (Lane, 2011, 2017). Even if the field of evolutionary theory is a rich tapestry of schools and opinions, and debates often get considerably heated, most if not all scientists squarely subscribe to the fundamental Darwinian notion that you can get to species without invoking Spirit in any of its guises.

Creationists, including Wilber, often seem to use the healthy controversy within this field of science as, or perhaps only as, an argument for the need to postulate Spirit. In defense of Wilber, some integralists (e.g., Reynolds, 2019) have claimed he is able to see the spiritual dimension of evolution because he uses his Eye of Spirit, whereas science is limited to the Eyes of mind and senses only, leading to a materialistic worldview. This raises the question: what additional insight into biological phenomena is gained by using such a form of extra-scientific knowledge? Reynolds argues that Eros or Spirit is not in any way a creationist God or Deity, but rather behind "everything that arises." This contradicts Wilber's many statements that evolution is "Spirit-in-*action,*" in my opinion. But even if that were the case, its absence or presence wouldn't make any empirical difference. Like beauty, Eros seems to exist only in the eye of the beholder, but not in any objective, empirical sense. Does that make the notion of Eros theory or poetry? (Visser, 2017).

In summary, Wilber has rarely engaged the modern synthesis in a serious manner (and often ridiculed it), has not dealt with the extended synthesis and its many offshoots, has recommended his students to read Michael Behe, the front man of intelligent design, quotes creationists such as Hugh Ross, and at the same time claims to have "the only theory that can actually explain the mysteries of evolution" (Wilber, 2017, p. 14). To date, Wilber's sympathies and affinities do not appear to lie with the realm of evolutionary science.

How or Where Do Ken Wilber and Evolutionary Science Meet?

Given this situation, we should now ask, has Wilber contributed to our understanding of evolution, either by intelligently commenting on current scientific schools or debates of evolutionary thought or proposing a theoretically viable explanatory model of his own? Given the above analysis, the answer must be no, in both cases. Neither intelligent design nor Integral Design has been able to clarify how biological complexity has emerged under the influence of Spirit. This is and will remain a religious belief which is hard to reconcile with the scientific method. This is Wilber's vision in a nutshell, as expressed in *Integral Spirituality*:

> That drive – Eros by any other name – seems a perfectly realistic conclusion, given the facts of evolution as we know them. Let's just say there is plenty of room for a Kosmos of Eros. (Wilber, 2006a)

By repeating this catechism instead of substantiating it, Wilber is mixing up the factual language of science with the poetic language of religion, without attention to precise terminology ("by any other name"). Rather than offering positive evidence for the existence of Spirit, he is making an *inference*, in the same way that intelligent design uses this argument (Dembski, 2006), about the necessity for such a hypothesis.

Based on his writing thus far, it is difficult to discern the reach of Wilber's understanding of science. He often argues that science relates all phenomena to chance, and since chance by itself is obviously not able to produce biological complexity, "something other than chance" is needed. Here's a typical quote, taken from *A Brief History of Everything* (Wilber, 1996, p. 23):

> In other words, something other than chance is pushing the universe. For traditional scientists, chance was their god. Chance would explain it all. Chance – plus unending time – would produce the universe. But they don't have unending time, and so their god fails them miserably. That god is dead. Chance is not what explains the universe; in fact, chance is what that universe is laboring mightily to overcome. Chance is exactly what the self-transcending drive of the Kosmos overcomes.

Science, however, sees chance as only one factor, lawfulness or necessity or selection being the other. Evolution is decidedly *not* the result of mere random chance, but also of non-random selection (Isaak, 2003).

Without any opportunity for a positive theory of evolution, explaining in detail how Spirit intervenes or how biological complexity is an expression of Spirit, the only alternative left for Wilber is point to developments in science which, if not prove his thesis, at least seem to go *in the right direction*. In this context he usually mentions two scientific giants: theoretical biologist Stuart Kauffman and complexity scientist and Nobel Prize winner Ilya Prigogine.

As stated before, Kauffman's field of research does not touch directly on the processes of speciation or adaptation. Regarding these fields Kauffman is a Darwinist (Kauffman, 2019, p. 87: "Darwin was right"). And since Wilber does not specify what this self-organization (understood by him as a spiritual phenomenon) is able to accomplish in terms of biological complexity (eyes?, wings?, cells?, multicellularity?) – in stark contrast to Kauffman's attention to detail – he can not present Kauffman as one of his allies. True, Kauffman (2008) has written *Reinventing the Sacred*, but that refers to an explicitly naturalistic sacredness or sacred naturalism. Contrary to Dawkins, he is not in favor of combatting religion, but instead wants to open our eyes to the wonders of nature itself. By elucidating empirical processes of self-organization, Kauffman may not be Wilber's ally at all, but in fact an adversary, given Wilber's explicitly spiritual agenda.

The same is true for Ilya Prigogine, who won a Nobel Prize for his work on dissipative structures, which are able to create "order-out-of-chaos." Wilber (1995) reads into this phenomenon a transformative power of nature or even matter, which suits his spiritual philosophy. But in my opinion this interpretation is questionable. Self-organization definitely exists, and in many forms, but it is not something that can be explained or clarified by a single cause. What Prigogine actually discovered is that *under certain conditions* of energy flows, matter tends to assume a new structure, which processes ("dissipates") this energy in a more efficient way. Order can thus be produced *by exporting disorder*. Likewise, we humans continuously have to take food in order to live and thrive and would otherwise die. A constant energy input is therefore needed to keep living organisms going. This pre-eminent role of energy flows or gradients is consistently overlooked by Wilber in his writings when discussing the emergence of complexity.

For example, in a recent video (Wilber & De Vos, 2019) he argues for a self-organizing drive *intrinsic* to matter:

> That's why Prigogine, Nobel prize winner in 1967 or so... the research he did demonstrated absolutely beyond a shadow of doubt, that even dead and insentient matter, if you push it far from equilibrium, it will escape its turmoil by jumping to a higher level of self-organization. Matter does that inherently! That is built in to it! You don't have to do something special, a funky thing to get it up and running.

This strikes me as a misunderstanding of the nature of Prigogine's discoveries. Matter reorganizes itself under the impact of energy flows or laws such as gravity, not because it "inherently" wants to do that. Indeed, when the role of these energy flows through matter is made explicit – as is done much more adequately in the so-called Big History literature (Visser, 2013, 2014c) – there is no longer any need to invoke Spirit to explain complexity. Again, Prigogine might not be Wilber's ally here, but instead his opponent.

This discussion relates to the wider field of entropy, which also is touched upon by Wilber in various recent online communications. Starting with the science story: The second law of thermodynamics holds that entropy – usually understood as disorder, but dispersion or diffusion is an alternative reading – tends to increase in nature, when no external energy is added to a system. Likewise, our Sun radiates energy in all directions, every single second of our lives, in huge amounts, lost forever in cold space. Only a tiny part of this energy output is captured by life on Earth to be used for the construction and maintenance of its cells. And interestingly, the more complex organisms are more efficient in capturing and dissipating this energy, either directly or indirectly. Thus, biological complexity emerges not against, but in accordance with this second law.

Wilber (1995) has given a rather different reading of these scientific topics. In his understanding matter itself is able to "wind itself up," as he phrases it, which he even extrapolates to the universe at large. In *A Theory of Everything* (Wilber, 2000, p. x), he states:

> The second law of thermodynamics tells us that in the real world, disorder always increases. Yet simple observation tells us that, in the real world, life creates order everywhere: the universe is winding up, not down. The revolutionary new understanding found in "chaos" and "complexity" theories maintains that the physical universe actually has an inherent tendency to create order...

Note again the word "inherent" here. Wilber glosses over the scientific distinction between the second law, which works across the cosmos *globally*, and *local* pockets of complexification, which are possible given the right conditions of energy flows. We clearly cannot just rely on "simple observation" in these matters. Simple observation tells us also that the sun rises… Wilber does not seem to go beyond this superficial analysis. But it is the Sun, not Eros, that in the end fuels the evolution of life on Earth in all its many forms.

In this quote, Wilber creates an artificial contrast between seeing the second law as pervasive, and the new findings of complexity science about the emergence of complexity, but that contrast is non-existent. Rather, it is a *paradox*, which is well understood by Big History authors, such as David Christian, but not by Wilber:

> According to the second law of thermodynamics, the tendency of the Universe is for simplicity. There are no drivers for complexity… And since the universe tends to wind down, constant energy input is needed for complexity. (Christian, 2015)
>
> How does the universe create complexity given the law of entropy?... with great difficulty. And with every next step, the going gets tougher… We, as complex creatures, desperately need to know this story of how the universe creates complexity, despite the second law." (Christian, 2011)

Again, Wilber's claim that some famous scientists support his position (without explicitly endorsing his spiritual view of things) is spurious. Much more reflection is needed here.

I would like to suggest the following metaphor to clarify the differences in worldview that are at stake here (Visser, 2018). Imagine we are paddling upstream on a river, that, naturally, flows downstream. Wilber concentrates upon our upward movement (i.e. psychological growth) and says: "we make an awful lot of progress on a river that is supposed to flow downstream!" By doing so, he overlooks the enormous amount of energy that is needed to make that happen (i.e. to sustain life). And he feels the curious need to cast doubt on the second law of thermodynamics ("the world is not winding down, it is winding up!"). Without grounding in basic science, he needs to invent his own cosmic dynamic of an Eros-in-the-Kosmos and an "Erotic Universe," as

I have documented in an extra online chapter of *Ken Wilber: Thought as Passion* (Visser, 2014b). Wilber wants to have his rivers run upstream.

Conclusion

Overseeing the questionable strategies Wilber has followed to argue for his Spirit-driven "theory" of evolution, in contrast to science, I see these three as most problematic.

- Claiming failures of science – Wilber has been skeptical about science's capacity to explain certain forms of biological complexity (similar to arguments provided by intelligent design). Examples he has used are: the evolution of eyes and wings, the human immune system, multi-cellularity, morphogenesis, regeneration, etc. In none of these areas has he reported on current scientific research. He has also not been explicit in where he draws the line between what science cannot explain and what it can.

- Claiming support from science – Wilber has suggested similarity between his ideas and those of famous scientists, without adequately accounting for major differences, even though he has at the same time acknowledged that mainstream scientists do not support his spiritual view of evolution. When we look beyond verbal similarities such as "the universe is creative" and search for actual explanatory mechanisms, the fundamental differences between Wilber and these authors does not result in support from science.

- Claiming superiority to science – Wilber has continuously proclaimed the superiority of his own "theory" of evolution without meeting the demands of theory formation in science. What he has to offer is in fact not evolutionary theory but evolutionary theology. A true theory clarifies natural processes and breaks them down into explicit steps, by suggesting possible mechanisms. Wilber's "Eros-theory" is by definition and in principle not able to do just that.

In baseball, the rule is "with three strikes you are out." I do think that when it comes to Wilber's dealings with these fields of science, given these failed strategies, the game is over.

When responding (briefly and unsystematically) to my challenges, he (Wilber & De Vos, 2018) once called me an "extremely conventional evolutionary theorist" (I have actually no idea what he means by this: does it refer to Evolution 1.0, Evolution 2.0, Evolution 3.0?).

> I am always getting criticized by extremely conventional evolutionary theorists, like Frank Visser, because I postulate Eros, an inherent novelty in the cosmos... which by the way is Whiteheads point, the 'creative advance into novelty'. *Eros*... Stuart Kauffman, self-organization is built into the universe. *Eros*... Ilya Prigogine, a Nobel prize winner. 'Order out of chaos'. Even insentient matter, when pushed far from equilibrium, jumps into higher levels of order. *Eros*...

But name-dropping and sloganeering is not the same as doing responsible science or philosophy. In Wilber's universe one is either a flatland scientist in favor of neo-darwinist, flatland reductionism, or a spiritual theorist who sees the Divine as active everywhere in nature.

As I have argued, there is a huge middle ground that is covered by contemporary evolutionary science, which is worthy of further careful exploration. Instead of repeatedly claiming "support" from a handful of famous theorists, who are either long dead or have not been in contact with Wilber, it is more honest to acknowledge the theoretical vacuity and lack of sophistication of the whole notion of "evolution as Spirit-in-Action." A more robust integration of evolutionary theory within Integral Theory is called for.

Finally, some humility is in order when it comes to making far-reaching knowledge claims. Science, and especially evolutionary science, is such a wonderful field of human endeavor, that it does not deserve to be maltreated by "the world's greatest philosopher." Evolutionary theory is a rich and varied landscape that cannot be dealt with in a few sketchy paragraphs. Furthermore, shouldn't the integral movement open up its windows by now to theoretical approaches outside of its own ideological domain? The absence of a healthy culture of debate, the strongly emotional reactions of Wilber to theoretical challenges over the years and the intellectual apathy of the integral community around matters of science do not help us in our search for assessing the truth and validity of Wilber's particular views on evolution.

A Hierarchy of Consciousness from Atom to Cosmos

Marilyn Monk[1]

Introduction

Listening to, or reading, presentations of consciousness studies can often be very confusing. There are several reasons for this. One reason is that the presentation may come from two very different viewpoints. It may be focused on human consciousness or it may be coming from an interest in the idea of an all-pervasive consciousness throughout the cosmos (known as panpsychism). In this respect, experientially, as humans, we could ask – do we, as individuals, have consciousness or does a cosmic consciousness have us (so to speak). Many of us will relate to different personal experiences that suggest that both are true according to how preoccupied we are with immediate everyday concerns about the survival of our physical being and its ego, versus more meditative states, perhaps in nature, of being outside of our selves and 'aware of being aware.' We will come back to this seeming contradiction later.

Another reason for confusion is that the discipline, or background knowledge and interest of the scholar of consciousness may be very different. For example, it may be mystical/religious, philosophical or scientific. Each of these categories may be further subdivided in a way that influences the approach and outcome of the investigation. For example, the scientific approach may involve scholars in psychology or psychiatry (e.g., Velmans, 2017; Beauregard et al., 2018), in quantum mechanics (e.g., Marman, 2018), in Darwinian evolution (e.g., Velmans, 2012), or biology and geology. The approach from biology can be further subdivided into neurology (Koch et al., 2016; Chalmers, 1998) or, as in this article, evolution.

The literature covering the various approaches to the study of consciousness is huge and diverse and often confusing and will not be covered here. In this paper, the approach is limited to a simple mechanistic biological analysis of how consciousness is involved in increasing complexity in evolution – from atoms, to molecules, to tissues and organs, to life forms, to populations of life forms and then, after introducing the life forms into ecosystems, continuing on through solar systems, and galaxies to cosmos. With a few rules governing the nature of the formation of this interconnected hierarchy of evolution it is a scheme that delivers consciousness as primary and defines matter as derivative from consciousness in evolution.

This approach was initiated by the definition of consciousness as given in the Oxford dictionary ('aware of, and responsive to, surroundings', and see below) which, when viewed from

---

[1] **Marilyn Monk** is UCL Emeritus Professor of Molecular Embryology at GOS Institute of Child Health, London. Her research has covered mechanisms of DNA replication and repair, bacterial viruses and plasmids, amoeboid cell signaling and aggregation, development of single cell molecular biology, DNA methylation and epigenetics, regulation of gene activity in development, mechanism of Lamarckian inheritance and, clinically, preimplantation diagnosis of genetic disease, deprogramming to embryonic stem cells, and embryonic genes re-expressed in cancers.
m.monk@ucl.ac.uk

SOME RIGHTS RESERVED

the author's own experience in biological research, immediately pointed to the view of consciousness known as panpsychism. Panpsychism (defined as consciousness pervasive throughout existence) has been postulated throughout the ages by mystics and philosophers such as Plato, Spinoza, Leibniz, and James (cited, along with many other early proponents of panpsychism, in Goff (2020). It holds that consciousness is present in all natural bodies that have a unified and persisting organization (both pertinent aspects of the players in the scheme presented here).

My own research has involved many levels of biological existence, experimenting in each case towards a greater understanding of the mechanisms of increasing complexity and survival in evolution. In summary, my laboratory research has involved:

1. Atoms – the use of radioactive isotopes of atoms in enzyme substrates to isolate mutants in DNA synthesis to identify the genes involved, and the development of highly sensitive single cell molecular biology to measure specific enzyme activities in single cells (many references in the review by Goto & Monk, 1998, and for clinical relevance see Monk et al., 1987).

2. Molecules – the study of genes, gene modifications and gene expression, involved in DNA replication and repair, gene expression in embryos, germ cells and cancers, regulation of gene expression in development, epigenetic modification directing gene activity, molecular mechanisms of Lamarckian inheritance (see many references in the review by Goto & Monk, 1998, and earlier references e.g., Monk & Kinross, 1972; Monk, 1990; Adjaye et al., 1997; and later references, e.g., Goto et al., 1999; Zuccotti & Monk, 1995).

3. Viruses and plasmids – the study of DNA/gene transfer cell to cell, e.g., transduction in *Pseudomonas aeruginosa*, indirect induction of phage lambda (Monk, 1969), plasmid transfer (see e.g., Holloway & Monk, 1959; Monk & Clowes, 1964).

4. Cells – bacteria and amoebae, mammalian primordial germ cells, eggs and sperm, preimplantation diagnosis of genetic disease, embryonic stem cells, cancer cells (see e.g., Alcantara & Monk, 1974; Monk, Boubelik & Lehnert, 1987; Monk et al., 1987; Monk & Holding, 1990, and for clinical relevance Monk et al, 1987, Monk & Holding, 2001).

5. Multicellular tissues and organs – cell signaling in differentiation, conglomeration of cells into higher order structures, amoeboid migration, embryonic and fetal development (e.g., Alcantara & Monk, 1974; Monk & Petzoldt, 1977; McMahon & Monk, 1983).

It is not necessary to read all these references for the proposal of consciousness of evolution described here. They are cited only to provide evidence from 'person-at-the-bench' science for the known material mechanisms showing how consciousness drives the evolution of more and more complex conglomerations of matter in existence ascending the hierarchy from atom to cosmos (and, as extinction equals creation, back again). The model presented here is not about the *evolution of consciousness* in humans or other life forms by Darwinian variation (random mutation and selection) – a study that runs into considerable difficulties (see e.g., Velmans, 2014). Rather it is concerned with the *consciousness of evolution*. It supports the oft-quoted statement of Max Planck, the originator of quantum physics – "I regard consciousness as fundamental. I regard matter as derivative from consciousness."

Definition of Consciousness

Yet another reason for confusion in consciousness studies is the different definitions and uses of the word 'consciousness' itself. The human centred studies are more aligned with the Cambridge Dictionary definition of consciousness, namely, "*The state of understanding and realizing something.*" Certainly that has been the main focus since Descartes who confined consciousness and mind to humans. It is this field of research which is concerned with the so-called 'hard problem' (Chalmers, 1996). The hard problem is human centered and is about how the physical mechanisms of brain processes give rise to subjective feelings – i.e., how the brain gives rise to experience, or phenomenal consciousness, and mental states with phenomenal qualities – 'the neural correlates of consciousness' (Strawson, 1994, Koch et al., 2016). These studies, looking for some uniform neural explanation of a particular experience, may be complicated by the different influences of the variable and interconnected neurological, physiological and psychological (experiential memory) backgrounds of the different individuals in the study (see e.g., Marman, 2018).

The other viewpoint that consciousness is pervasive throughout the universe (panpsychism) proposes that all matter has an element of consciousness. This approach is more aligned with the definition of consciousness from the Oxford Living Dictionary – "*The state of being aware of, and responsive to, one's surroundings.'* Immediately, most readers of this article will see that 'aware and responsive to surroundings' applies to so many things. All life, plant and animal, is aware and responsive to surroundings and thus appears as conscious according to this definition. Recently there has been much debate about consciousness in animals and even in plants.

In this article I will not be concerned with the human centred studies and the hard problem but with the more pervasive view of consciousness extending throughout the cosmos. The approach will be based on what is known scientifically and on the Oxford Dictionary definition of consciousness – aware of, and responsive to, surroundings.

Aware of, and Responsive to, Surroundings

One of the problems of considering consciousness in lower life forms, and non-life forms, is the use of various terms in consciousness studies that seem to apply more to humans. The term 'aware' is certainly more of a human concept and may be taken to include a huge range of consequences of awareness – sensations, feelings, self-reflection, memory, imagination, and so on. But, in biology and geology, when we consider the simple definition – aware of, and responsive to, surroundings – we see that consciousness extends outside of the human realm and, in lower life forms, or even non-life forms, we see 'awareness' more simply as mechanisms of 'detecting' or 'sensing' the surrounding environment. With this broader concept of awareness we can start thinking about consciousness at the level of the atoms, molecules, cells and tissues and work our way up from the micro- to the macro-cosmos, looking for the material mechanisms of consciousness (sensing environment and responding to change) at each level of increasing complexity.

The starting rules for my hierarchy scheme of consciousness in this paper are views that are well known already – specifically, that everything is interconnected to everything else and everything is in service to its own higher order structure. For example, when I was at Edinburgh University in the early 70s, Henry Kacser taught the concept of interconnectedness as metabolic flux in the metabolome – the intricate interconnected biochemical pathways within a cell (Kacser & Burns, 1973). Also in Edinburgh, Conrad Waddington taught the concept of service as epigenetic programming of different cells in the body to serve their higher order structures – the different tissues and the organs (see Noble, 2015).

As humans, we experience consciousness with our senses of sight, hearing, touch, smell and taste. There are also messages from body to brain (e.g., hunger or pain), and messages from brain to my body for different emotions. And indeed, messages from within the environment of self of mental functions of memory, imagination and the various machinations of the human mind. These are functions of human brain/body communication and a lot (but not all) is known about material mechanisms involving transmission of signals between body and brain via circulating informational molecules binding to specific cell receptors. However, it is evident that all forms of life have consciousness but at different levels of sophistication, and with a very different range of consequences of their consciousness. A worm is conscious in that it detects and responds to changes in its environment. It can feel a harmful stimulus (pain). A snail can remember where it belongs in the territory of the back garden. A bacterium can detect a gradient of sugar involving special receptors on its surface and respond by transferring this information to trigger its means of movement – its flagellae – to swim towards a food source. The degree or sophistication of consciousness at different levels of life's complexity is different. This article is not concerned with mechanisms of evolution of increasing sophistication of consciousness. Suffice to say, it is difficult to see how random mutation and selection over millions of years could bring this about. However, note that Lamarckian inheritance of acquired characteristics by epigenetic modifications of genes passing through egg and sperm (Zuccotti & Monk, 1995) from parents to offspring might well be involved. Evolution by Lamarckian inheritance occurs rapidly by selection of individuals better adapted to their surrounding environment.

The scientific approach in this article is to consider the material mechanisms of consciousness at each level of increasing complexity in the hierarchy of evolution from atom to cosmos. And, indeed, material mechanisms are known at all levels. Surprisingly, with such a materialist approach throughout, the analysis shows that matter is derivative from consciousness and displays a sense of belonging, meaning and purpose of every thing throughout evolution and existing today.

An Example of Consciousness in a Lower Life Form

As an example of consciousness in a lower life form we can look at an area of the author's own research in the early 70s (Alcantara & Monk, 1974), namely, how slime mould amoebae (*Dictyostelium discoideum)* become aware of changes in their environment, and how they respond. Aggregation of the individual free-living amoebae into a multicellular structure is triggered by their awareness that they have run out of food. The individual amoebae detect the change in environment (due to starvation) and start to emit a signal (pulses of cyclic AMP), which diffuses out into the territory (see Figure 1). The fastest signaling amoebae establish and take control of their territories. Amoebae in a territory, detecting the gradient of cyclic AMP, make movement steps towards the source and emit their own signal to attract amoebae further out to join the aggregation. So the signal is relayed out and bands of amoebae move inwards. They move towards each other as they come closer to the centre to make amazing spirals looking like galaxies.

The aggregate formed in the centre of the territory forms a multicellular slug capable of movement over a greater distance than the individual amoebae could manage. The slug develops phototactic and thermotactic receptors at its tip so that it moves towards the light and heat at the soil surface where it forms a fruiting body. To make the fruiting body, a third of the amoebae in the slug sacrifice their lives to create a stalk which bears the spores (differentiating according to their position in a gradient in the remaining two thirds of the slug) aloft so that they will be distributed to better feeding grounds. It is amazing how clever this organism can be when triggered by the need to move to new pastures. It is a good example of consciousness in a lower organism – how cells sense and respond to their environment at several stages in order to differentiate into a multicellular structure. The material mechanisms are known.

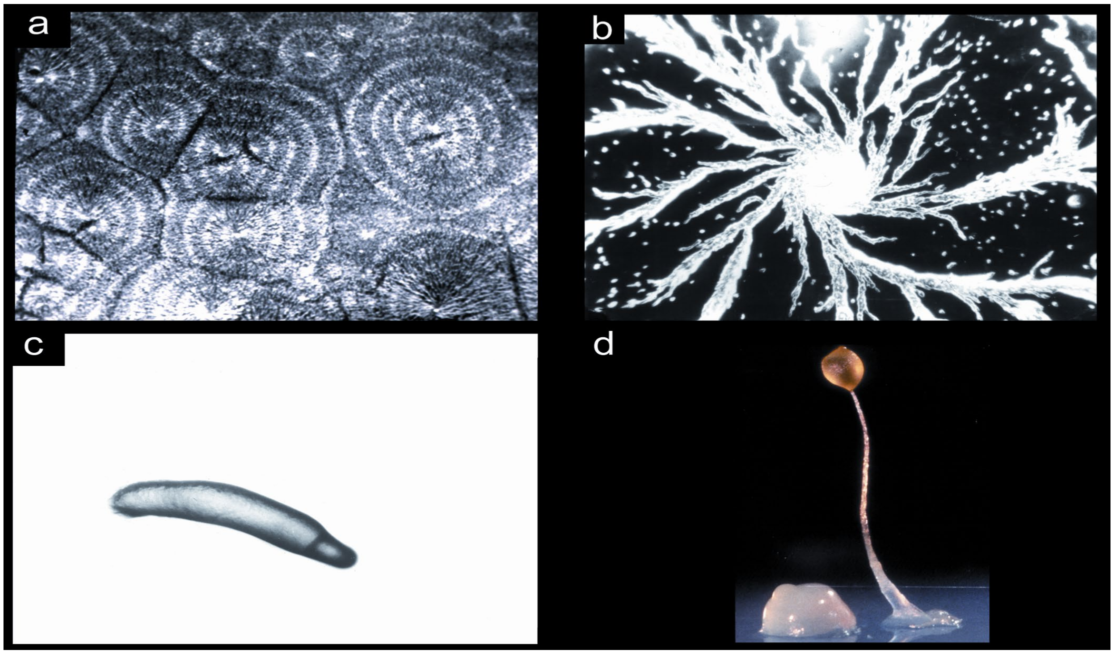

Figure 1. *Aggregation, slug movement, and fruiting body of Dictyostelium after the amoebae detect they have run out of food. a) Individual amoebae in the field, triggered by starvation, start to emit pulses of cAMP and those with the shortest periodicity form territories with surrounding amoebae relaying the signal outward and making a movement step inward towards the source. b) As they approach the centre, amoebae are attracted to each others' cAMP signal to form streams and spirals. c) The slug, measuring several centimetres, has receptors that detect heat and light, and so can detect, and move the distance to, the soil surface. d) At the surface the slug transforms into a fruiting body. A third of the amoebae in the slug sacrifice their lives to form stalk to bear the spores aloft (Alcantara and Monk, 1974).*

This example also demonstrates how consciousness can operate at the level of whole populations of individuals. What about lower and higher levels of complexity – atoms, molecules, cells and tissues, or ecosystems, solar systems and galaxies? Does it make sense to say that the mechanisms of consciousness are still material throughout?

A Hierarchy of Consciousness

In the following model of a hierarchy of consciousness, the mechanisms at each level of complexity depend on interconnectedness (awareness of surroundings) of the parts serving (responsive to surroundings) their higher order structure. A model of interconnectedness of increasing orders of complexity is shown in Figure 2. This is a highly simplified model. It does not include subatomic particles and, with respect to life, there are millions of species of life existing on earth (and an approximately equal number gone extinct) that are linked in various ways by the process of evolution. In the hierarchy model here they are simply presented as flora and fauna. Also, for simplicity, the model of interconnected hierarchy is illustrated as a binary interconnected model limited (for ease of illustration) to only eight orders of increasing complexity from atom to cosmos. The shift to a higher order structure at each level of complexity is due to a conglomeration of multiple members from the level below. The coming together of parts ensures their greater survival. The model as shown is binary although, clearly, at each level more than two parts form the conglomerate that is the higher order structure at the next level. For example, variable numbers of atoms conglomerate to make molecules and there are around 3000 molecules in a cell.

There is another simplification in the model of hierarchy as shown in that there is one exception to the general rule of conglomeration of parts to form a higher order structure. This is in the transition from populations to ecosystems. It is clear that ecosystems are not simply an aggregate of populations of living organisms (flora and fauna). In order to progress towards cosmos, I have introduced a stage (ecosystems) including elements from another hierarchy of increasing complexity of non-life forms – soil to rocks to mountains, rivers to lakes and oceans – in which to place the populations of animals and plants. The aim is to present an image representing the linking of all levels of increasing complexity into one interconnected structure where every existing organised structure is interconnected and aware of immediate surroundings and so on throughout the evolution of existence.

Analysis of this hierarchy of interconnectedness will show that, at each level, the parts are in service to ensure the survival of their higher order structure in evolution – the electrons to the atom, the atoms to the molecule, the molecules to the cell, and so on (although remembering that equally there is extinction from cosmos to atoms in the other direction). The parts in service at each level are conscious in that they detect and respond to their surrounding environment. The mechanisms are material and known at all levels of complexity as we will now examine – starting with the atom

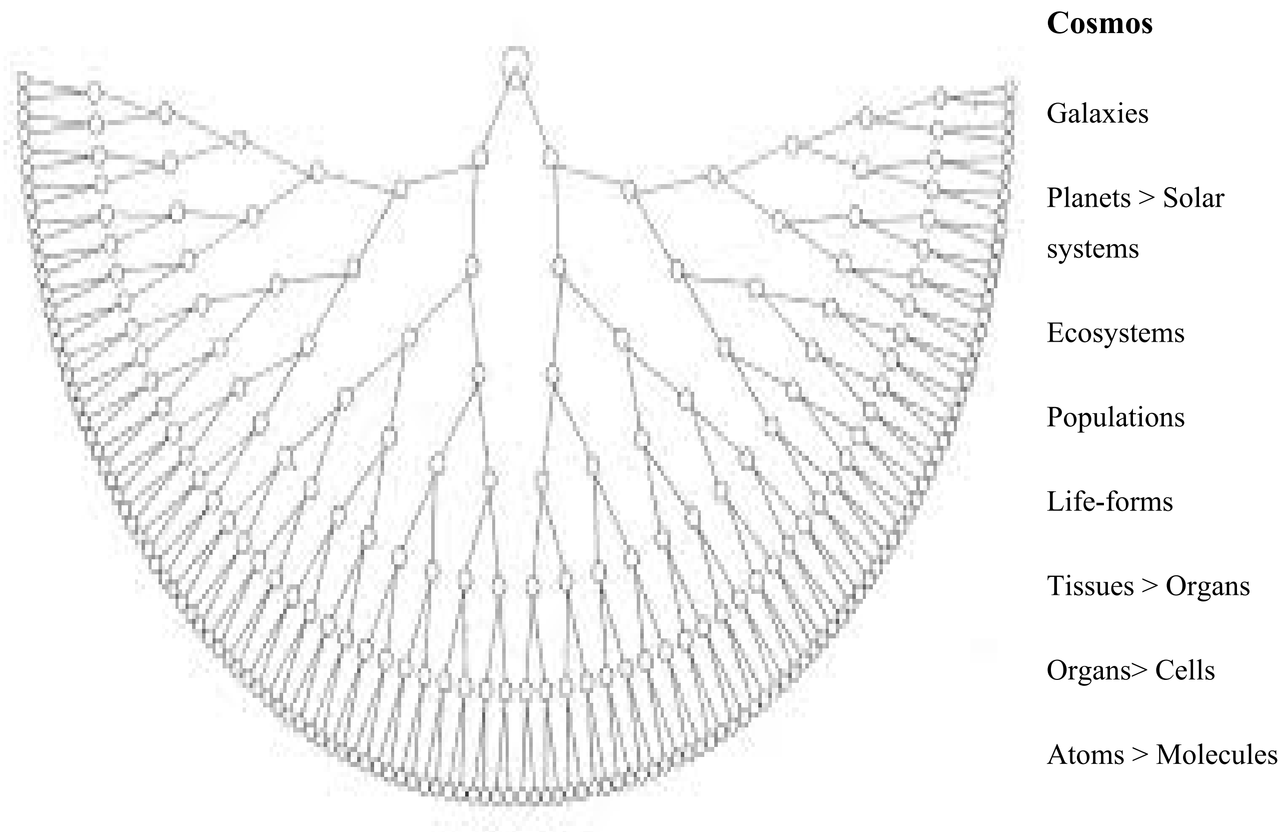

Figure 2. *A diagrammatic representation (an inverted ancestry model from Gregoire, 2014) of an interconnected hierarchy of increasing complexity in evolution. This is a binary model for simplicity – the number of atoms making a molecule, or molecules making a cell, and so on, is greater than two. It shows a path of increasing complexity going through life forms. A similar hierarchy could be created for non- life and the step from populations to ecosystems in this diagram brings soil, rocks, mountains, rivers, lakes and oceans into the ecosystems in this scheme of interconnectedness. The hierarchy also operates in the other direction from cosmos to atoms with extinction approximately equal to creation.*

Atoms to Molecules to Cells

Atoms consist of a balanced number of neutrons and positively charged protons in the nucleus and negatively charged electrons in their orbits (Bohr, 1923). For example, a carbon atom has six electrons and six protons, an oxygen atom has eight protons and eight electrons. When the balance of protons, neutrons and electrons is disturbed, the atom decays. The components or parts of the atom are in service to their higher order structure – the atom.

Next, we have the molecules which consist of several atoms joined together by covalent bonds formed by a sharing of electrons in their outer orbits. The stability of molecules is variable depending on the strength of bonding between the atoms and the possibility, or not, of their bonding with another atom or molecule. One could say that the atoms are in service to the molecule and the mechanisms by which they bond and form the molecule are understood.

Molecules interact in an interconnected way to form cells. There are approximately 3000 biochemical pathways, with their associated enzymes and cofactors, interconnected in every cell. This is called the metabolome. Interconnectedness means that a change in any part (substrate, product, enzyme, cofactor) of any biochemical pathway affects all the pathways in the cell. The interconnected changes in all pathways is called metabolic flux, which can be observed by mass spectrometry. For instance, one can distinguish a starvation metabolome, from an addiction metabolome, from a sugar eating metabolome, and so on. Metabolic flux shows the interconnected pathways detecting and responding to a changing environment – our definition of consciousness. The molecules are serving their higher order structure – the cell. Mutation any of the key genes supporting growth and survival of the cell leads to cell death.

Cells to Tissues to Organs to Life-Forms and Populations of Life Forms

Referring back to Figure 2, we see that the next items in increasing levels of complexity are tissues and organs. In the case of a mammal (e.g., a mouse) as an example of a life form, all cells in the body have the same 20,000 genes. The differentiation into over 100 different cell types in the body is directed by signaling from the different environments of the cells in the developing fetus to programme their genes to be on or off, up-regulated or down-regulated. The programing is by epigenetic mechanisms – modifications superimposed on the DNA of the genes to regulate their expression (for example, methylation of cytosine in the DNA, Lindsay et al, 1985). In computer language the genes are the hardware and the programming is the software. The cells detect information from their environment in the developing fetus and respond by differentiating into cells with the required function (bone, muscle, blood, skin, nerve, and so on). In this sense they are conscious and serving the tissues and organs of the body. Studies on other life forms in the laboratory – e.g., nematode worms, flies, fish – show similar material mechanisms governing differentiating cells to establish the required functions for service of the cells to the different tissues and organs. If the cells cease to serve their tissue, for example by epigenetic deprogramming (Monk et al, 1987) due to cessation of informational signaling, the tissue may be lost (e.g., to death or cancer).

The next level I have included in Figure 2 is populations. Populations of multiple members of a species can form a higher order structure – for example, the slime mould slug (Alcantara & Monk 1974), the beehive, or the Portuguese Man O' War jelly fish. Here we have a colony of organisms taking on different roles and working together for the sake of survival of the greater whole (and themselves). Again, the material mechanisms of service are known in populations of individuals in service. For example, in the beehive the genes of different worker bees – nurse, farmer, forager, warrior – are epigenetically programmed to differentiate them to perform their specific tasks. If they do not serve their higher order structure, the beehive will die and so will the bees. Anarchic behaviour in worker bees causes destruction of the beehive and death of the bees.

Ecosystems, Planets, Solar Systems and Galaxies

As the model moves from populations to ecosystems in Figure 2, it will be obvious to the attentive reader that we have departed from the concept of conglomeration of multiple parts into a higher order structure at each level. Ecosystems are not an aggregate of populations of flora and fauna. Here, another hierarchy of increasing complexity of non-life is introduced – the soil, rocks and mountains, and rivers, lakes and oceans of the ecosystems – in which to place the living populations of animals and plants. Beyond ecosystems the model returns to conglomeration of parts to make a greater whole – ecosystems to planets, planets to solar systems, solar systems to galaxies.

Also, at this point, it is time to observe two further 'rules' I have postulated within the system. We have been looking so far at two rules – interconnectedness within and between levels of increasing complexity, and service of parts to their higher order structure at each level. A third rule is that, even though the parts are in service to their higher order structure at each level, the parts do not know what they are serving. However, if they do not serve correctly the higher order structure will not survive. The fourth rule is that the whole is looking after its parts at each level.

The next level of complexity included in this hierarchy is the ecosystem. An ecosystem is an interconnected biological community of interacting life forms and their physical environment. It will have the right pastures for the herbivores, the correct herbivore to predator ratio, it will have rivers (and maybe an ocean) and mountains and forests. The parts are in harmonious interconnected service to the whole for survival of the ecosystem. The mechanisms are known. As we know, if the forests are destroyed, if a river is diverted, if the top predator is removed (e.g., the wolves in Yellowstone Park), these disturbances can unbalance the whole interconnected system leading to the destruction of the ecosystem.

And the case is the same with the next level – our solar system. Although we trust that our planet will safely look after us in the future, a glimpse at the past is not so reassuring as it contains inhospitable ice ages and a meteor that wiped out the dinosaurs. And now, our planet is threatened by climate change and the melting of the ice caps or, possibly, a solar flare. Indeed, only last year, Nature published a report of a distant star spitting out a giant flare that packed 100,000 times more energy than any seen from Earth's sun (Argiroffi et al., 2019). This is the first clear detection of a remote star emitting a kind of eruption known as a coronal mass ejection that until now have only been seen from our sun. The authors state – 'such explosions may wreak havoc on surrounding worlds.'

Consequences of this Model of Aware (Interconnected) and Responsive (Service) Consciousness

We have reached our galaxy and the cosmos, and we can summarise the preceding arguments in the following key points:

1. A view of a hierarchy of interconnectedness between, and within, levels of increasing complexity from atom to cosmos. There is a survival advantage, which drives evolution, in increasing complexity due to the coming together of parts into a greater whole. Everything exists in a field of belonging. Outside that field the parts cannot exist.

2. At each level the parts are conscious – aware of, or detecting, or sensing, their surrounding environment, and responsive to change, in service to their higher order

structure. The material mechanisms of service are largely established and known at each level of complexity.

3. The parts do not know what they are serving.

4. The higher order structures are caring for their parts.

Some important consequences flow from this scheme as follows:

a. Interconnectedness means that reverberation (or flux) can move through the whole system, top down or bottom up or middle out. For example, a solar flare, or human interference, might disrupt ecosystems, scattering populations to new environments, leading to cellular adaptation and reprogramming of genes. Or the human race could become extinct leading to recovery of damaged ecosystems.

b. Flux through the system leads to events that do not seem to have a material mechanism because consciousness – awareness and response to change in surroundings – is happening across several levels of complexity. This allows the possibility that aspects of the paranormal might be explained in this way – certainly in space (e.g., remote viewing). However, it is not so clear how paranormal events happen across time, for example telepathy between previously interconnected elements in the hierarchy. Here, connections made between individual aspects in the interconnected system due to flux must be recorded in some way and recoverable later. What could be the mechanism of recording previous events in time and re-membering?

c. Service of parts to the higher order structure to which they belong is essential for survival at all levels of complexity and ensures development in evolution. However, it is important to note that this is not an imperative because it is also essential that there is turnover – the replacement of the old with the new. Extinction is equal to creation – for all species that exist on earth today an approximately equal number have become extinct. So, equally, the hierarchy model can be seen in reverse orientation as the higher orders of complexity return to molecules and atoms. The rule is that death equals birth. One wonders whether this implies that birth and death apply to our whole cosmos.

d. This scheme of things establishes consciousness as the unity of everything, and the belonging to the unity of all things in service to their higher order structures and the whole. It shows that consciousness is primary and that matter is derivative from consciousness (as defined in this paper). It fits with the experience of individual consciousness of the individual part located at its particular position in the hierarchy, and the experience of consciousness of the whole through the interconnectedness and belonging to everything else. It celebrates *belonging*, and *meaning*, and *purpose*, for everything on planet earth and beyond. This creates a sense of a spiritual context even though the scientific approach is material.

e. In humans, unconditional service, often imbued with the sense of unconditional love, is an evolutionary selectable in that it activates the pleasure centres of the brain. Beyond that, unconditional love for all beings and every thing works to support the flourishing of all. Loss of service, or anarchy, leads to loss or, in this scheme, extinction.

Conclusions

In the introduction, it was suggested that individual humans personally experience that they possess their own consciousness but sometimes they can have a sense of belonging to a much greater consciousness of the whole. The same could apply to our dual experience of free will and predestination. In the scheme presented here, both could be true depending on the viewpoint – whether the observer is viewing self from their own particular location in the hierarchy or, in dropping the mind, has gone outside of self into possible experience of the reverberating interconnected whole (a 'peak experience'). One might ask what does it mean to drop the mind? Observation of our own human mind activity shows that it seems to exist in past and future. Indeed, projection of past into future could be seen as an imperative for survival of the physical self and its ego. Dropping the mind has an experience of presence - no past and no future.

We also observed that the study of consciousness was complicated by whether the analysis was from the viewpoint of the human mind or from a perspective of pervasive consciousness throughout existence (panpsychism). The latter view, followed in this paper, was prompted by the Oxford Dictionary definition of consciousness as 'aware of, and responsive to, surroundings' and the author's own experience as an experimental biologist. In addition, we noted that consciousness studies are further complicated by the many approaches depending on the background discipline of the scholar – religious/mystical, philosophical, psychological, quantum physics, geological and biological.

The approach here is not concerned with quantum mechanics. My observer relationship in this scheme does not alter the understanding of the biology of increasing complexity in the hierarchy of evolution. It derives purely from my own experience in biological research at many levels of study - observing and playing with evolving life forms. It is just another view to add to the already existing multiple views of consciousness. It may be simplistic but it does however remove what is clearly known from reproducible science from the darker areas of confusion created by quantum mechanics and philosophical and psychological analyses of consciousness.

Finally, can we draw a line at the top of this hierarchy? Remembering that parts cannot know who or what is being served at all levels, and that the higher order structures are looking after their parts, we cannot yet know the next higher order structure beyond cosmos. It is plausible to argue that beyond this entire scheme of all that is known to exist, beyond cosmos, there may be a yet higher order of complexity.

An Epistemic Thunderstorm: What We Learned and Failed to Learn from Jordan Peterson's Rise to Fame[1]

Jonathan Rowson[2]

Abstract: The cultural pressure to endorse or reject public intellectuals wholesale can be problematic, perpetuating groupthink and diminishing scope for intellectual growth, societal maturation, and political imagination. On encountering public figures who appear to be both right and wrong, sometimes simultaneously, perhaps dangerously, there is scope to be more creative and less reactive in our response. In the illustrative case of Jordan Peterson, commentators often oriented their analysis within a conceptually moribund political spectrum; e.g. Peterson is “alt-right” attacking “the radical left.” Social media echo chambers lead some to read that Peterson's “fanboys” were “misogynist trolls” while others heard that his critics were “virtue signaling snowflakes”. The tendency of print and broadcast media to seek a defining angle diminishes rather than distills complexity; for instance, Peterson's fame was associated with a perceived crisis in masculinity, but that was not the whole story. “Petersonitis” is introduced here as a serious joke to describe the intellectual and emotional discomfort that arose from the author's attempt to seek a fuller understanding of complex characters in a divisive political culture. In a response to Peterson's book, *12 Rules for Life: An Antidote to Chaos*, twelve relatively dispassionate perspectives on his contribution are offered as an antidote to the language of allergy and infatuation that surrounded his rise to fame. Peterson is described here as symptomatic, multiphrenic, theatrical, solipsistic, sacralizing, hypervigilant, monocular, ideological, Manichean, Piagetian, masculine, and prismatic. First person language is used to reflect the author's experience of Petersonitis, after having been drawn to Peterson's online video lectures, debating with him in a public forum, and gradually clarifying the nature of the limitations in his outlook and approach. It is hoped that the paper will help readers recognize, recover from, and ultimately transcend Petersonitis, and to appreciate the much wider application of the idea.

Keywords: Books, Christianity, conversation, culture, Jordan Peterson, Jungian, masculinity, media, Piagetian, postmodernism, psychology, public intellectuals, reductionism, spirituality, transgender, twitter.

Prolegomena

I first heard the expression "It's never about what it's about" in the context of marital disputes. Couples fight about diary clashes that shouldn't have happened, phone chargers that shouldn't have been moved, surfaces that should have been wiped, and other domestic emotional landmines. Yet the intensity of the escalations and explosions that follow are usually about something altogether more challenging in the relationship – something requiring time and discernment to uncover. This refrain – it's never about what it's about – is not literally true, but it's a useful notion more generally, and it helps when we consider: what was that Jordan Peterson thing about?

I'm sure it wasn't about Jordan Peterson as such. The rise to fame and notoriety of this particular intellectual, spiritual and political warrior during his apotheosis in the period 2017-2018 was experienced by millions of fans and critics as a kind of epistemic thunderstorm; questions of what we know and how we know them felt unusually charged and salient. Peterson had a significant impact on literally millions of readers and viewers as individuals and a direct influence on cultural influencers including The Intellectual Dark Web and Rebel Wisdom. However, the Peterson phenomenon also represented a significant collective epistemic growth opportunity that I believe was mostly squandered. For this reason, I have done what I can to convey the deeper aboutness of the Peterson moment.

I met Peterson in January 2018 and began writing soon after to make sense of a strange cocktail of conflicted thoughts, feelings and convictions, resulting in the following paper several months later. Once I finished writing, I felt free of Petersonitis, as described below, but it lingered just a little because it proved difficult to publish. I approached several longform journalism and academic outlets, often supported by contacts, but the cultural gatekeepers I encountered wanted a clear appraisal of Peterson's main ideas, or they wanted commentary on the world's reaction to Peterson, both of which became well-trodden terrain as a result. Instead, I sought to examine the Peterson phenomenon as a touchstone for our capacity for epistemic and spiritual growth at a cultural level, which is part of my professional purpose at Perspectiva; the paper's length and tenor stemmed from that deeper objective, and felt necessary, even if that meant it didn't 'fit' into the places I wanted it to go.

I have paid little attention to Peterson for the last two years, but Patricia Marcoccia's documentary *The Rise of Jordan Peterson* (2019) appears to share my premise that this was a teachable moment that got away. More directly pertinent to Integral Review is Rebel Wisdom's interview with Ken Wilber on Peterson[3] which was promising because a rigorous developmental perspective is lacking in discussions by and about Peterson. However, I felt Wilber missed an opportunity to highlight the principle limitation of Peterson's thought, namely his ambivalence and neglect of 'bottom right' phenomena in the terms of integral theory's quadrant map. Those inter-objective features of reality, including the economic and institutional structures that are driving technological and ecological systems, are arguably the preeminent issues of our time, but Peterson very rarely goes there, and when he does it is mostly to offer generic praise of capitalism.

---

[3] https://www.youtube.com/watch?v=bDjCnFvz11A

Fully developing the significance of this point would require another paper but it can be intimated with some comparisons. *The Age of Surveillance Capitalism* by Shoshana Zuboff is broadly about how Facebook and Google are extracting and manipulating data in a way that is destroying culture and making people unfree, while *The Uninhabitable Earth* by David Wallace Wells is about the economic logic of fossil fuel extraction destroying nature and with it, our only viable home. These critically acclaimed and high-profile books were both published in 2019, after Peterson's peak, but neither have received anything close to the same cultural attention, and neither represented the same kind of epistemic inflexion point. With that in mind, I think what my article below is *about* is an attempt to show that Peterson's psycho-spiritual offerings are valuable when they help us contextualise and transform the socio-economic logics that are precipitating ecological and technological peril, but they are positively harmful when used to distract us from them or downplay their importance.

On a more conciliatory and appreciative note, Peterson's Foreword to Solzhenitsyn's *Gulag Archipelago* for Vintage Classics also came out in the interim and served as a reiteration of what is driving Peterson – fear of societal collapse and an acute awareness of just how much worse everything could be. He is right about that – a functional society is a fragile achievement in need of vigilance, not a default setting to be taken for granted or casually lamented. The teenage climate activist Greta Thunberg can perhaps be thought of as Peterson's nemesis in this regard. In fact, I find it curious that Greta rose to Peterson-like levels of fame just after Peterson began to retreat from view. While Peterson appears to thrive at life's social game and regularly wins the battle for attention, Thunberg has said it is her high-functioning Asperger's and selective muteness that helps her see through the social game that everyone is caught up in. That game of performativity and pretending is arguably what is preventing us from attending to the life-giving ecological foundations that should matter to us most at this moment. Alas, the controlled urgency we need to feel to collectively attend to the fragility of human civilisation is often lost in the more palpable entertainment of culture wars and identity politics that facilitated Peterson's rise to fame.

At the time of writing in the summer of 2020, Peterson appears to be convalescing after an extended period of ill-health relating to depression and withdrawal from benzodiazepines. At a personal level, I wish him a speedy and full recovery. If I have a regret about the following article, it is that with hindsight it looks like I was trying not only to outsmart Peterson, but to be seen to be out-smarting Peterson. In that sense, my approach was perhaps unconsciously hubristic or foolhardy, but it was nonetheless a wholehearted effort. Peterson himself is currently not prominent in public discourse but may soon become so again. And many others might rise to fame in a similar way. I am grateful to Integral Review therefore for giving me a formal platform to be able to share what I think the Peterson phenomenon was about.

Introduction

Jordan B. Peterson is easily misunderstood. He is a clinical psychologist and Professor of Psychology at the University of Toronto but is now known as a forceful cultural commentator who emphasizes the value, depth, and dignity of individual responsibility in an embattled manner, as if civilization is at stake. His magnum opus is not the self-help bestseller, *12 Rules for Life: An Antidote to Chaos*, but a much deeper inquiry into myths and archetypes, *Maps of Meaning*, published two decades earlier. Peterson's online academic lectures derive from this earlier textbook and are where his intellectual quality is most evident; these videos are viewed in their millions by his fans but mostly ignored by his critics (Peterson, 2018a). Peterson's news interviews, public debates, online discussions, and social media comments on the other hand typically relate to identity and ideology and are often much less judicious, though they attract widespread attention. He is possibly the best-known public intellectual of the time, though some argue that his fame is symptomatic of a global intellectual crisis rather than a product of the quality of his thought (Robinson, 2018).

Reaching a settled view on Peterson's contribution is difficult because it manifests in so many ways. While he has built an impressive academic career respecting data and nuance, he is often undiscerning in his political diatribes. Critics of any aspect of Peterson's work tend to be typecast by his fans using their icon's favored dramatic terms and tenor. They are often assumed to be LEFTIST NEOMARXIST POSTMODERNIST FEMINIST SOCIAL JUSTICE WARRIORS who think only of GROUP IDENTITY, abdicate INDIVIDUAL RESPONSIBILITY, and know nothing of BEING – Peterson's favored term for human existence. The online Peterson phenomenon is powerful because it is built on academic prestige, fueled by personal charisma, and driven by oppositional identities.

On January 16, 2018 I spent three hours with Jordan. We had a civil but charged hour-long discussion at the Royal Society of Arts in London. I arranged additional shorter interviews for my organization Perspectiva, which, like Peterson, seeks to increase awareness of the relationship between psychological and spiritual sensibility and societal challenges. That evening, thinking the day had gone well, I made the mistake of reading the RSA Video YouTube comments where I am "the host" but verbally flogged like an insubordinate outcast. The conversation has now been viewed over 200,000 times – modest by Peterson's standards – but there have also been several spin-offs on Conservative online platforms viewed in their millions, including vintage clickbait titles like "Leftist Host SNAPS at Peterson – Instantly Regrets it!" I have been approached by strangers at the hairdressers, the gym, the library, and in the playground of my son's school, who recognize me from the Peterson video. The encounter, including preparation and reflection, gave me an appreciation for Peterson's quality and intensity, the vituperative loyalty of his fans, and the atmosphere of allergy and infatuation that surrounds his work.[4] It also gave me acute *Jordanpetersonitis*.

Jordanpetersonitis
Jawh-duhn-pee-ter-suhn-awy-tis/
Complex noun. Also, abbr.: "Petersonitis"

1. *Intellectual and emotional discomfort caused by the perceived need to reach an informed view on the significance of Jordan Peterson's cultural contribution, but being unable to, despite considerable effort.*

Petersonitis is not a casual slur, but a serious joke to recognize the cultural indigestion caused by Peterson, and an attempt to redirect the public conversation. We are probably past "peak Peterson" but we must go beyond describing Peterson's work or even offering a conventional critique – because the Internet is saturated with both. *Petersonitis* serves as a conceptual tool to investigate a confounding experience that may contain the seeds of cultural maturation. The pressure to pick sides is ultimately much more important than the complex public character of Peterson himself, but is well illustrated through the Peterson phenomenon:

Symptoms:

- *Mesmerized intellectual excitement at the spectacle of passionate thinking, laced with confusion at what exactly is being said.*

- *Moral dumbfounding, arising from the intuition that Peterson is wrong in important ways even when his reasoning is persuasive.*

- *Emotional exhaustion caused by too many hours expecting answers from an anguished face on a computer screen.*

I am not alone in calling for this broader reflection in the context of reactions to Peterson. *The Guardian*'s Oliver Burkeman (2018), for instance, took the rare step of devoting a column to resolutely *not* forming an opinion on Peterson:

> My wishy-washy ambivalence about Peterson has hardened into defiance: why the hell should I be obliged to decide, as seemingly every writer who encounters his work thinks they are, whether Canada's most controversial professor is A Good Thing or A Bad Thing? This sort of pressure … is a symptom of our hyper-partisan times, in which everything is politics … and it's your responsibility, as a good citizen, to adopt and then feverishly defend one sharply defined, absolutist viewpoint, come what may. (np)

2. *Derivative and general application: Feeling frustrated by the cultural obligation to approve/disapprove of a complex thinker for reasons of social or political identification, rather than to form a more discerning view.*

In the process of taking a political view on Peterson, as if casting a vote, we seem to be killing precisely the kinds of breadth and depth of perspective that might revitalize political imagination. As the writer Norman Mailer put it in the context of loving Jorge Luis Borges despite his reactionary political views: "I detest having to think of a writer by his politics first. It's like thinking of people by way of their anus" (Whalen-Bridge, 2008).

This counter-pungent preference is particularly important in the context of Jordan Peterson, because at the surface level, his politics are unsophisticated and divisive, and the language of infatuation and allergy towards him bifurcates accordingly. For some, he is reenchanting masculinity, reviving Christianity, and providing meaning and direction for thousands of lost souls; for others he is a crypto misogynist authoritarian offering banal advice with footnotes to dangerously entitled people. The answer is probably not to take either side or find a place in between, but to try an entirely different approach.

One of Peterson's favorite sources of insight is psychoanalysis, where a comprehensive diagnosis sometimes functions like a cure. What follows is not another attempt to reach a balanced view of Peterson's work – "he's right in some ways but wrong in others" – but to back up one level of abstraction and reflect on why such "balance," by tacitly endorsing the polarity that calls for it, offers neither catharsis nor transformation (Cooper, 2018).[5] Here, Peterson is not just another intellectual with some good and some bad ideas, but a test case for approaching difficult thinkers who intrigue us in some ways and annoy us in others.

For this, our conceptual language needs refreshing more generally. Distantly inspired by Peterson's injunction to be precise with words, and mindful of the title of his bestseller, *12 Rules for Life: An Antidote to Chaos*, I offer twelve conceptual tonics clustered in four trios: to explain the cultural phenomenon, describe his intellectual character, consider major thematic critiques, and offer hope for cultural learning and maturation. The tonics are micro-epiphanies, not revelations, but I hope they present the phenomenon from a wider range of perspectives and thereby help people recover from, live with, or transcend Petersonitis. It is for the reader to determine which of these is the proper aim.

Prevalence:

- *Petersonitis seems to be a minority affliction. It probably affects about 10 percent of the millions of people who come into contact with Peterson's work – the floating voters. Those who strongly like or dislike him (the majority) are immune due to political markers and other identity-based antibodies.*

1. Symptomatic

Intellectual prominence on the world stage usually requires the coalescence of at least three factors: the message, the messenger, and the moment. In Peterson's case, the message is that personal responsibility is sacred; the messenger is a charismatic psychologist; and, whatever optimists like Steven Pinker suggest, for many this moment feels demoralized, rudderless, and cacophonous. Perhaps there is also a fourth factor – the missing: Peterson's message resonates most with people – typically young men – who do not feel properly attended to in public discussions.

Peterson's ascent coincided with the rise and consolidation of powerful strong male leaders around the world, and he is cut from similar cloth: self-assured, identifying enemies, offering answers, and giving people something to believe in. While Peterson shares some qualities with

---

[5] Perhaps the most comprehensive engagement with Peterson's work as a whole is by political sociologist Brent Cooper (2018).

Trump (whom Peterson has said he would have voted for) or Putin, Xi, Erdogan, or Modi (Peterson, 2018b), the more challenging point is that in substance he's also like Noam Chomsky of thirty years ago, when, from a very different political vantage point, *Manufacturing Consent* offered the insight the moment was calling for, rallying students all over the world (Herman and Chomsky, 1988).

In a time of post-truth politics, Peterson emphasizes forms of metaphysical and personal truth that resist cultural assimilation. As ISIS barbarism was broadcast nightly, his online lectures illuminated what might be distinctively Christian about a civilization worth defending. In the context of economic competition from the developing world, the ominous impact of robotics on employment, and a generation likely to be poorer than their parents, his message of self-development gives people an alternative to despair and resentment that doesn't rely on forces outside their control. His rise occurred alongside a broader intellectual crisis in social democratic thinking, the eclipse of Obama, and the more general dearth of oratory and leadership. At such moments of social, economic, and political flux, when material questions do not have ready answers, spiritual questions become more salient. Who am I? What's the point of life? Peterson dared to offer some answers.

And how dare he! In a recent critique in the *New York Review of Books*, Pankaj Mishra (2018) remarked: "His apotheosis speaks of a crisis that is at least as deep as the one signified by Donald Trump's unexpected leadership of the free world" (np). In *Current Affairs* magazine, Nathan Robinson (2018) contextualizes that claim: "If Jordan Peterson is the most influential intellectual in the Western world, the Western world has lost its damn mind.… He is a symptom. He shows a culture bereft of ideas, a politics without inspiration or principle" (np).

The reasoning in these two cases and in many other critiques of Peterson is somewhat perplexing. In *On Liberty*, John Stuart Mill (1859/2016) wrote: "In all intellectual debates, both sides tend to be correct in what they affirm, and wrong in what they deny." This captures why the Peterson phenomenon is important. If part of the perceived problem is that Peterson is now revered by many despite his faults, surely the other part is that people who make their living from intellectual reflection seem dumbfounded as to why, unable to appreciate the value in what he offers. That is also a symptom, also a crisis.

In an atmosphere of rights inflation and ambient entitlement, Peterson's balancing emphasis on personal responsibility is timely. As the Christian tradition often feels moribund, his hermeneutic approach to Bible stories creates precious streams of revitalization. In his emphasis on knowing the truth experientially and striving to establish one's own locus of agency and authority, he saves people from pervasive groupthink. In an increasingly desacralized world, his capacity to yoke lessons from religion without being tethered to a limited conception of "belief" is necessary. Taking a stand against the pressure to conform to unthinking approaches to equalities and diversity, he has provoked public reflection on the difference between genuine care for others and the demands of political correctness. In his admiration for neglected thinkers like Piaget and Jung, he has cultivated new resources to enrich our understanding of ourselves and the world. And with his attempted integration of philosophy, biology, psychology, and theology, he is an exemplar of intellectual excitement – embodying the power of ideas.

Peterson's swift ascent to fame began with his public refusal to agree to Bill C-16, a new law in Canada requiring people to use non-binary pronouns like '*eir*', 'zie', or 'they' for transgendered people. Peterson insists he is not transphobic. His principled stance against the top-down imposition of a new regulation of grammar touched a nerve that is still in spasm. That nerve apparently relates to the question of which groups have what kinds of power over the individual and who gets to decide what follows. Peterson's well-articulated public position on that issue, combined with his freely available lectures on psychology, mythology, and self-help has earned him hundreds of thousands of fans and critics.

But the root of the nerve goes deeper still. Much of Western intellectual life, including some of the mistrust between sciences and humanities, stems from an unresolved tension between two paradigmatic approaches to knowledge. Underlying many of the debates Peterson is involved in, is a broadly modernist either/or mentality: defining to exclude, reducing to explain, and narrating as if there was one story, and they are up against the both/and insistence of postmodernism, in which ideas are fuzzy edged and cross-pollinating, context is critical, and values and stories are plural. This is the underlying skirmish in which questions of gender fluidity become not niche but emblematic – are you *either* a man or a woman, or can you, somehow, be neither or *both*?

Peterson's broader loathing of postmodernism stems from treating it like a discrete cultural virus requiring mass inoculation, rather than a diverse and divergent set of ideas that one might learn to live with and sometimes through. He has a tendency to argue by shutting down both/and complexities and doubling down on either/or rhetoric; some things are true and others are false, and science is our guide. "No! Wrong!" he is fond of saying. Those with both/and sensibilities say that truth may be scientific and objective but it is also subjective and relative, and power and culture are also our guides. The either/or sensibility neglects context and perspective and uniqueness. However, in its insistence on its own exclusive truth, postmodern both/and self-righteousness subtly contains the either/or it purports to transcend. That is why "it's all relative" is an absolutist statement, and Blake's celebrated line "to generalize is to be an idiot" is, by definition, an idiotic thing to say.

The challenge is that both claims remain somewhat true. The truly inclusive approach – the real "both/and" – contains "either/or" *and* "both/and." Perspectivism of that kind is chastened objectivism, in which we forgo the immaturity of mad relativism but insist on putting perspective at the heart of realism. We learn from relativism but don't submit to it; we have a both/and perspective but don't lose our either/or discernment or resolve. That kind of perspective is the cultural pattern waiting to manifest, but it is palpably lacking in Peterson and in most reactions to him.

Intensity of Petersonitis:

- *Mild: Feeling confounded that someone previously unknown in the world of ideas is suddenly so famous and won't go away. Some report that their initial impression that he is an unhappy man offering banal advice made them ill at ease with their own judgment.*

- *Acute: Sensing that his attempt to better connect our psyches with our societies could help us transcend our political polarities and culture wars, only to feel dismayed when his reactionary views and caustic manner reinforces them.*

Knowledge of minority and disempowered perspectives is morally and epistemologically necessary, but the truth is not subsumed by perspective. We can still celebrate, let's say, the industrial revolution, while remembering it was built on slavery, colonialism, and a fossil fuel frenzy with enduring consequences. And we can accept that by some metrics, the world is in better shape than ever before, but in the context of ecological and technological volatility it doesn't follow that we are going in the right direction. Moreover, the data feels obtuse when viewed from the perspective of Syrian refugees, mentally ill teenagers, the working poor, and vanishing small island states. It is possible *both* that we have never had it so good *and* that everything has to change, *and* to argue for a course of action on that premise (Rowson, 2017). If we can work towards understanding that *something* is real and we are partly right and partly wrong about it most of the time, we might, as Peterson puts it, "grow the hell up," though not in the way he seems to have in mind.

2. Multiphrenic

Peterson shifts between reflective, iconoclastic, avuncular, demagogic, compassionate, scientific, and philosophical modes of communicating. I don't think this is an act as such; the protean performance is who he is. One moment he cries in solidarity with forsaken young men on BBC Radio 5 live, and the next he eviscerates his prime minister Justin Trudeau for his enthusiastic tweet supporting women's rights in Canada, asking, "Is that the murderous equity doctrine?" This shifting quality is intriguing and spellbinding, but it makes the task of locating his judgment and motivation like trying to pin jelly to a wall (Peterson, 2018c).[6]

Peterson is multiphrenic. The concept of multiphrenia originated in Kenneth Gergen's *The Saturated Self* (1991), before social media, and it has even greater resonance today because most of us play multiple roles in life. We are saturated with myriad opinions, values, and ways of life, filtered through an array of relationships, projects, and commitments, and viewed increasingly in short nuggets: 800-word reviews, tweets, and video clips. In this world of snapshots we can choose which aspect of ourselves to bring forth, but more often that is decided for us by the medium and the context. In this respect, Peterson illustrates the sociologist Erving Goffman's theory that the self is constituted through presentation; who we are is the sum total of the parts we play for the audiences in our lives, and those parts do not always speak to each other or for each other (Gergen, 2007).

As his former colleague and friend Bernard Schiff (2018), who was responsible for hiring Peterson at the University of Toronto but who now believes Peterson is dangerous, puts it:

> Jordan exhibits a great range of emotional states, from anger and abusive speech to evangelical fierceness, ministerial solemnity, and avuncular charm. It is misleading to come

---

[6] Brett, Sarah. & Arthanayake, Nihal. 2018. Radio 5 live – Afternoon Edition 15/01/18 [radio show] www.bbc.co.uk/programmes/b09llgnl

> to quick conclusions about who he is, and potentially dangerous if you have seen only the good and thoughtful Jordan, and not seen the bad. (np)

The concept of multiphrenia makes sense of why Peterson can appear quite so impressive, without always actually being so. He wields multiple intellectual weapons with panache, a compelling approach for audiences looking for fragments of meaning to tweet and practical advice to act upon rather than coherent world views to understand life as a whole. If his grasp of psychometrics and statistics from social psychology doesn't persuade one part of you, his archetypal stories from depth psychology will move another part of you. If the case studies from his practice as a clinical psychologist don't speak to your personal experience, his references to neuroscience and evolutionary biology might.

3. Theatrical

Peterson is a performer. Thoreau said people go fishing all their lives without realizing that it's not fish they are after, and millions watch Peterson not so much for the content but for the drama. They are drawn in by the resolute deliveries of choice words, the chastening paternal voice, the summoning pauses, the clipped passive-aggressive responses to challenging questions, the clenched lips, narrowing eyes, and latent rage rendered tolerable by occasional folksy charm, humor, and imploring hand gestures. His literary success is driven less by the quality of his insight (which varies) or prose (which is prolix) than the spectacle of his articulate and assertive public performances, which linger. He lectures by thinking aloud with extraordinary physical energy, constantly pounding and gesticulating, embodying the thinking process as a form of prowess, putting Rodin's inert statue to shame. He might possess what Max Weber (1947) calls "charismatic authority."[7]

In person, Peterson is civil, with flashes of conviviality, but he harbors more melancholy than most and bristles easily. In his demeanor I see some of Daniel Day Lewis's elegance but also Count Dracula's balefulness. There are also traces of Jack Nicholson's Colonel Jessop in *A Few Good Men*, especially in the film's climactic line: "You can't handle the truth!"

Peterson's insistence on truth is heartfelt, and part of the theater, including statements such as: "The Logos is symbolically represented in the figure of Christ.... The West has formulated a symbolic representation of the ideal human being. And that ideal human being is someone who speaks the truth to change the world" (Transliminal, 2017).

That's a good example of a Peterson contention: pithy, compelling, intriguing, apparently deep, even exhilarating, but also question-begging, leaving you wondering if you really understand, or want to (the notion of "ideal human being" has a dark history). Peterson may offer the truth, but it rarely feels like the whole truth.

---

[7] "A certain quality of an individual personality, by virtue of which he is set apart from ordinary men and treated as endowed with supernatural, superhuman, or at least specifically exceptional powers or qualities. These as such are not accessible to the ordinary person, but are regarded as of divine origin or as exemplary, and on the basis of them the individual concerned is treated as a leader ... How the quality in question would be ultimately judged from an ethical, aesthetic, or other such point of view is naturally indifferent for the purpose of definition."

***

4. Hypervigilant

Isaiah Berlin said that if you want to understand a thinker you need to grasp what they are fighting against. In Peterson's case that is not difficult. He fears and loathes the brutal forms of collectivism in Hitler's Germany, Mao's China, and Stalin's Russia, and his home is decorated with memorabilia of these dangers, what a *New York Times* profile described as "a carefully curated house of horror" (Bowles, 2018).

Peterson's formative influences included trying to uncover the psychological roots of ideology during the Cold War – how large groups of people could become so attached to ideas that they might destroy the world to defend them. Peterson doesn't see today's liberal order as a historical inevitability but more like a precious, even miraculous, achievement that is extremely fragile. He may not be wrong, but he holds that view in a way that feels deeply personal.

My speculation is that Peterson's odyssey has made him hypervigilant. He admits in an interview with *The Tablet* that he has experienced "derealization" every day since his rise to fame began: "When something happens to you and you can't believe it is your life." Peterson seems to have a higher than average level of threat response, which becomes even higher when he relives the genesis of his derealization at the University of Toronto. His body language tightens and tone of voice sharpens whenever he speaks of THE RADICAL LEFT or POSTMODERN NEOMARXISTS (Stanford, 2018).

Peterson sounds shrill and extreme to some, but wise and prophetic to others, and the difference seems to depend on how threatened a person feels on a day-to-day basis. Moral psychologist Jonathan Haidt has shown that conservatives are likely to be more concerned with threats to sanctity, order, and tradition than most liberals can even imagine, and their driving concern is often not social progress but personal survival (Haidt, 2013). In an interview with the *Radio Times*, Peterson admits: "I think, because of my proclivity to depression, that negative things hit me harder than they hit people in general" (Hodges, 2018). His main concern is to help people hold down a job and have a family; and social order – he wants us to keep creating, refining, and following the rules that allow us to have a viable economic and political system.

By offering a combination of archetypal myth and conventional vigilance, Peterson's main product amounts to what the author of *The Listening Society* Hanzi Freinacht calls "dark depth" (Freinacht, 2016). Pankaj Mishra's reference to "Fascist Mysticism" perhaps misses the point here. Peterson's focus is how we return from depression and anxiety to normality, and how we try to avoid falling again (Mishra, 2018). He places little emphasis on the numinous aspects of spiritual experience or soulful visions of transformation or transcendence.

His preferred reference points for collective meaning and action are still Mao's revolution and Stalin's gulags, and not, say Aldous Huxley's Island Utopia. Peterson speaks of "the evil trinity," of "equity, diversity and inclusivity" as "a mask of virtue under which is something truly awful." Petersonitis arises because while his vigilance about respecting the sovereignty of individuals over the group is justified by history, his hypervigilance – ongoing heightened threat awareness and extreme sensitivity to group overreach – is not.

5. Sacralizing

I began the RSA public event by asking Peterson about the dream he shares near the start of *12 Rules* because I think it is the key to understanding him and his following:

> I was suspended in mid-air, clinging to a chandelier, many stories above the ground, directly under the dome of a massive cathedral. The people on the floor below were distant and tiny.… I have learned to pay attention to dreams, not least because of my training as a clinical psychologist. Dreams shed light on the dim places where reason itself has yet to voyage.… I knew that the cross was simultaneously, the point of greatest suffering, the point of death and transformation, and the symbolic center of the world.

He describes how he returned to anonymity and was beginning to fall asleep when a wind was trying to blow him back to that place, from which there was no escape. He seems to have taken this experience as a kind of existential if not divine revelation: "The center is occupied by the individual. Existence at that cross is suffering and transformation – and that fact, above all, needs to be voluntarily accepted."

Then he asks: "How could the world be freed from the terrible dilemma of conflict on the one hand, and psychological and social dissolution, on the other. The answer was this: through the elevation and development of the individual, and through a willingness of everyone to shoulder the burden of Being and take the heroic path."

In our discussion, he seemed to think there is something sacred about individuals taking responsibility and sorting themselves out. His response was striking: "It's not even that there is something sacred *about it*. *That is what's sacred* … the source of the sacred is that idea."

There are other ways of viewing the sacred; sociologist Gordon Lynch considers it "an inherent structure in morally boundaried societies," and clearly the nature of that structure and those boundaries varies, with many forms that are not about the sanctity of individuals (Rowson, 2015). For Peterson, however, the hero myth, with its journey quality of figurative dragon slaying, is the heart of the matter – the code to living a meaningful life.

The idea is not particularly new. Peterson does with analytical psychology what Joseph Campbell's *Hero with a Thousand Faces* did with comparative literature, and what many other thinkers have attempted before and since. Moreover, the heroic journey towards individuation as life's meaning is arguably a distinctly male emphasis. Carol Gilligan (1982) and Sarah Blaffer Hrdy (2009) among others would question the universality of Peterson's idea of the sacred, which may instead be reflected in the aesthetic unity of skillful cooperation or fuller self-knowledge through the experience of profound and deepening interdependence.

On reflection, what Peterson is offering is sacralized Nietzscheism or mythologized existentialism. It's not *Christian*. Peterson admits he has not read René Girard (1979), which is a strange scholarly oversight given the extent of his research for his first book, *Maps of Meaning*. Girard's influential line is that the archaic sacred is the religious ritual ethos of violent sacrifice to pacify the tribe and appease the gods; the purpose of God in Christ is to overcome this form of the sacred and institute the reign of ongoing peaceful self-sacrifice in community, which is the new sacred, symbolized by the act of communion supper.

Without that kind of resolution, Peterson is suspended between Nietzsche and Christ.[8] He is drawn to Nietzsche's iconoclastic freedom from herd morality, but he can't go all the way with his nihilism. And he is drawn to Christ as the Logos incarnate, the ultimate truth teller, and meaning maker, but his individualism precludes following where Christianity leads, namely to community, communion and charity. In that anguished space between Nietzsche and Christ he busks with psychometrics and archetypes, singing the blues about bearing the burden of being.

6. Solipsistic

Peterson's apparently heroic individualism is actually an existentialist isolationism. Humility and activism in synthesis is the hard-won achievement of the best of religious communities of practice and those they work with. But if, like Peterson, you write about the *Logos* but don't work in communion somehow, whether through church-going or otherwise, you don't discover that synthesis or contribute to it. Instead Peterson has found himself looking at a computer camera, wearing a headset and microphone, charging hundreds of dollars for a forty-five-minute online "ask me anything" call, whereby random people seek *his* advice about *their* life, watched not by a shared community but by the atomized masses (Bowles, 2018).

These points have political implications. Climate change, for instance, is not a discrete environmental issue but a collective action problem at every level of society, from the home to the office, all the way to the UN. It calls not merely for individual personal responsibility but also shared cultural and democratic responsibility; what we seem to lack is precisely that sense of collective ownership for the problem and our responsibility towards it.

It is not enough to trust people who are competent, as Peterson suggests we should, because the people with economic and political power who are ostensibly competent are tragically letting us down (Rowson, 2013). Activism arises from the impression that we need to walk the talk of collective action at scale. In her Nobel Prize-winning lecture, political economist Elinor Ostrom – celebrated for her studies of collective action solutions – makes the point elegantly: "Extensive empirical research leads me to argue that … a core goal of public policy should be to facilitate the development of institutions that bring out the best in humans."

Peterson would agree with Ostrom on this point, but they may differ on the question of what "the best in humans" means. Before going on stage at the RSA we had a relatively short and focused interview in which I tried to connect Peterson's interest in Jean Piaget to human development more generally. I asked whether he felt "self-authorship" – in which our judgment is truly our own rather than a mélange of social conventions – was the ultimate stage of human development. Peterson built a company around the idea and comes across as quintessentially self-authoring – the locus of authority is within oneself, not the social surround. However, Robert Kegan is one of many theorists to argue there are stages beyond self-authorship; in his model, for instance, the subsequent stage is the self-transforming mind or inter-individual stage (Thomason, 2012).

---

[8] I am grateful to Ian Christie for this astute way of putting it.

In this advanced stage of maturation, we gain an additional perspective on our own perceptual processes and implicit ways of knowing; we start to see our own personal ideologies. We can thereby form a more constructively critical relationship with our own world views and improve our capacity for empathy and intimacy with a wider range of people, because we cease to filter other people's experience through our own models of the world. Peterson broadly agreed with this idea intellectually, but seemed reluctant to concede the point explicitly, perhaps for pragmatic commercial reasons. That sounds like a cheap shot, but in a tweet he writes: "What's your vision? What's your strategy? What's your destiny? Take control with www.selfauthoring.com" (Peterson, 2018d).

As a trained clinical psychologist, Peterson should not only be familiar with but also skilled at inhabiting the world from the perspective of others, ready, willing, and able to set aside his own assumptions and constructions in order to view the world through another's eyes; to feel what they feel in the way that they alone feel it. And yet, the more I read and listen to Peterson, the more he sounds solipsistic. He clearly has regard and concern for the lives of others, but everything he encounters seems to be filtered through his own self-construction of the world, which he seems unwilling to critically reflect on beyond a certain point.

In the philosophical tradition, solipsism is about whether we can trust that anything outside of our own minds is real. Peterson is solipsistic in a looser and more figurative sense relating to intellectual character – he filters his definitions, anecdotes, and understanding of opposing views through his own personal coda. That only takes one so far, and it is precisely that additional self-transforming and inter-individual step that is called for at a cultural level today.

***

7. Monocular

Peterson is an expert and a generalist, but he is not an expert generalist. That distinction matters because of the many millions who trust his judgment in a general sense on the basis of specific intellectual authority.

The idea of an expert generalist is paradoxical but not oxymoronic. In theory, our very best philosophers, civil servants, political leaders, and writers are expert generalists – their defining skill is inclusive synthesis and their defining qualities are epistemic acumen and agility: know-how with knowledge, having enough expertise in one domain to value different forms of understanding, and knowing how to integrate them while retaining curiosity towards whatever remains unfamiliar.

With respect, Jordan Peterson is not like that at all. He is a social psychologist with an impressive publication record on psychometrics, a clinical psychologist with several years of client experience, and a depth psychologist with a flair for mythology and theology. But he sees everything through an augmented psychological lens, rather than showing any inclination to move between different forms of knowledge.

Peterson is not the first psychologist to come across as sociologically blinkered (the reverse also applies). Alienation, for instance, is experienced psychologically as estrangement from oneself as familiar places and people become strange; anomie is a loss of the structuring principles through which to orient ourselves through life. Peterson speaks directly to the experience of alienation and anomie psychologically, but they are also sociological phenomena with political and economic causes that he more or less ignores. His inclination is to reduce emergent social, cultural, and economic phenomena to the individual, operationalized into psychometrics like IQ, "agreeableness," or "conscientiousness." This meta-theory – methodological individualism – is a respectable approach to knowledge, but widely contested for good reason.

Peterson is an individual-differences psychologist with related passions and convictions, and nobody can be expected to know everything. In a now famous academic paper by Kieran Healy (2017), "F*** Nuance," the author argues against "a free floating demand that something be added." To say that Peterson is not an expert generalist is not to say he is a negligent thinker, but to help make sense of the personal and political limitations of his ideas.

Peterson appears skeptical about the conceptual integrity and explanatory power of many features of social, economic, and ecological systems and structures: gender, class, race, place, institutions, poverty, educational inequality, social capital, culture, habitus, reflexivity, emergence, finance. Such features of our shared reality are not merely irreducible to psychometrics but they also interrelate in ways that add to the complexity of credible social explanations. It would be refreshing to hear Peterson wonder aloud with a question like: how would a good anthropologist, political economist, sociologist, or ecologist think about this phenomenon? But he never does.

When Peterson inveighs against the use of "patriarchy" for instance, he seems to examine it like a psychometric and find it wanting, rather than a theory of society as a whole that points to a phenomenon we struggle to see because it is so thoroughly endemic that it shapes what and how we see. More generally, he lacks sociological imagination. He shows almost no interest in how power, elites, class, institutions, capital, and media come together to shape the world and indeed the individual; and why we might therefore be inclined to try to reshape it for the better. This is not a minor point. As we grow in understanding of those structural and systemic effects we see that social analysis cannot be reduced to psychometrics (Wright Mills, 1959).

In fact, Peterson has no compelling story to tell of what it might mean for society as a whole to improve itself. He has no endgame, as Seth Abramson (2018) put it. His vision seems to amount to whatever emerges from billions of politically disengaged individuals steadfastly getting their shit together, with a view to dominating each other. As Peterson is fond of putting it: good luck with that.

8. Ideological

In a sense, Peterson is hiding in plain sight. The essence of ideology is being possessed by a set of ideas that we cannot think critically *about* because we see with and through them. On this point Peterson approvingly quotes Jung: “People don’t have ideas. Ideas have people.”

Peterson has spent his career researching the dangers of ideology, but the sanctity and sovereignty of the individual clearly “has” him in the Jungian sense. And yet “the individual” is a historical and cultural construct like any other. My Oxford politics tutor Larry Siedentop’s (2015) *The Invention of the Individual* makes precisely this point. The idea of the individual is a key element in the construction of social reality in the West over the last few hundred years, but it is neither a metaphysical axiom nor a cultural universal.

Peterson juxtaposes ideological thinking with religious thinking by saying that while ideology offers self-serving partial truths (e.g. nature is wonderful and beautiful), religions offer fuller truths (e.g. nature is beauty and wonder, but also cancer, tsunamis, and death). Yet he seems unaware of his own recurring tendency to create and attack strawmen. The shortcomings of his views on postmodernism, for instance, have been highlighted in a range of places, most impressively by the writer Shuja Haider (2018). Peterson lacks substantive knowledge of postmodern thinkers and conflates postmodernism and neomarxism. When he is charged with conflation, he says no, or more like “NO!”, “WRONG!”; he says the postmodernists filled their own explanatory void with Marx, or the Marxists used the fashion of postmodernism to conceal their mischief, but the overall impression is of intellectual cobbling to serve a narrative, not judicious scholarly discernment. His hypervigilance about neomarxist ideology permeating the academy makes him sound McCarthyesque, as if there is a vast conspiracy afoot, but it seems more likely he has over-extrapolated from his own experience, again. But Peterson needs, even wants, his enemies, because his ideology takes a particular binary form.

9. Manichean

Manicheanism was a religious movement founded by the Persian prophet Mani in the third century; it teaches a dualistic cosmology of good and evil, light and darkness, and is used figuratively to refer to moral binaries. Peterson is Manichean. He is not a process philosopher who instinctively thinks in terms of complex systems in motion, cross-pollinating in pluralistic and unpredictable ways. He is much more absolutist and dualist in spirit. The intellectual structures he thinks with are mostly polar opposites, like pillars on a stage in which our dramas must unfold. He recognizes antinomies like good and evil, yin and yang, order and chaos, truth and falsity, individual and collective. However, he typically frames these juxtapositions as binary battles to be fought and won rather than co-constituting and porous relationships that we have constructed and might reimagine together.

Manichean views of the world are difficult to avoid. The human love of binaries has been widely theorized since structural anthropologist Levi Strauss revealed their cultural function. To orient ourselves by juxtaposing polar opposites is a natural way of thinking. Even so, Manichean thinking is not fit for purpose in a multipolar, multivalent, multimodal, multiethnic world, and it is compounded by our political spectrum. While the language of left and right once made some sense of class-based attitudes to the role of the state, politics is now about so much more; attitudes towards ecological and technological phenomena in particular cannot be parsed in terms of left and right, nor can national identity or the challenge to defend liberal democracy from populism.

In that context, the ambient pressure to choose a tribe and say “yay” or “nay” to the issue of the day is the problem that obstructs meaningful progress. We are building division within people that is culturally muted, while amplifying the divisions between people that are reinforced on a daily basis. Broadcast media selects guests with opposing views to get “both sides” of an issue, as if they were coins. Oppositional identities, in which we define who we are by what we are against, become the defining characters in public debate. We are rarely allowed to be curious but disinterested. Instead we must pick a side: Are you left or right, atheist or believer, with us or against us? This kind of ambient divisiveness is part of what Rowan Williams (2016) calls “the meta-crisis” of our times; namely how ecological, economic, social, and political crises are compounded by the limited and harmful ways we encounter, conceive, experience, and discuss them.

Peterson appears to be invested in perpetuating the individual/collective binary, which significantly limits political imagination. This distinction dissolves, however, when you realize that the self is constituted through communicative interaction between individuality and sociality. Hope lies in a richer notion of a social self, which was most fully worked out by the sociologist and process philosopher, G. H. Mead, but also features in Buddhist notions of interdependence. Rowan Williams (2018) makes a similar case from a Christian perspective in his new book *Being Human.* The juxtaposition that matters most may not be the individual and the community but the individual and the person. While the individual seeks to differentiate itself from what Peterson calls “the chaos” and thereby to control it, the person accepts they are partly constituted by that chaos, manifest in relationships of all kinds. We don’t need to accept a Manichean world view of perpetual struggle. Seeing reality in process-relational terms could lead to reform in various institutions. There is deeper hope in a vision of the interplay of systems, souls, and society in which we are at once lost and found.

***

10. Piagetian

Peterson speaks of Piaget, the relatively neglected intellectual giant of the twentieth century, in glowing terms, a genius who revealed the foundations of morality and whose ultimate aim was to unite science and religion.

A central Piagetian notion is the *schema*, our perceptual and conceptual patterning of thought through which we take in information (assimilation) and which changes our understanding (accommodation), leading to an equilibrated state which is the thing – our mental process – that we can’t really see because we see *with* it. In Robert Kegan’s language, consciousness *is* this “subject-object relationship”; we are subject to some things that we *are*, and we can relate to some things as objects that we *have*. We grow through differentiation and integration, slowly having things we were previously had-by, including thoughts and feelings and thereby relating to them better.

This distinction matters crucially in the context of ideology, which all too often possesses people. The point goes beyond Piaget and Peterson to a whole domain of research and practice based on an entirely different conception of the human being as a process of human becoming. We are developmental processes that adapt, evolve, and transform in response to an evolving set of cultural expectations that both shape and are shaped by human development. This developmental perspective on life offers not just a new psychology but a new biology and a new epistemology, and ultimately a new ethics and politics; it is a view of life (Csikszentmihalyi & Rathunde, 2014).[9]

In the video interview for Perspectiva, I asked Peterson whether a fuller understanding of development might help us transcend our culture wars by encouraging people to reflect on what they are subject to in their thinking. For instance, the postmodern contention that truth is perspectival may be a necessary evolutionary stage for a culture to pass through, and for individuals to adapt to and move beyond before we collapse into mad relativism. He seemed to agree, albeit very cautiously, suggesting it was rare to see that kind of evolution of perspective in practice (Perspectiva, 2018). He is right, but I believe it is precisely the necessary cultural evolution that the Peterson phenomenon points us towards and improving our discussion on gender is a fundamental part of it.

11. Masculine

If the conversation between Peterson and his critics teaches us anything, it is that we are bio-psycho-social-spiritual beings and any useful conversation about gender will reflect that.[10]

Men and women are different, even if in aggregate we are much more alike than different. And men and women are not just biologically different, because when it comes to human beings "just biological" is incoherent. Biology informs epistemology and therefore ethics, and, in that context, the idea of "women's ways of knowing" makes sense. It is not clear what kind of sense, and what follows politically, but that is a useful question to ask (Belenky, et al., 1986).

What is less useful is describing metaphysical heuristics in gendered terms. Chaos/Order is perhaps the defining binary of life in *12 Rules for Life* and Peterson identifies order as masculine and chaos as feminine, which seems gratuitous. The comparative mythologist John David Elbert (2018) draws attention to Ancient Egypt as one illustrative counter-example. It is worth quoting the extract in full to give some idea of the depths to which you have to plunge to make sense of this material and Peterson's selective use of it.

> One thing that Peterson doesn't tell you, because he's an absolutist – he likes everything to be flattened out into simple clear absolute unshakeable structures – is that in Egypt the valences regarding gender were reversed; the sky was female and the earth was male. The sky was the sky Goddess *Nut*, the starry expanse of the stars in which the *Pharaoh* was born in would come out of her and go back into her, become an embryo like the stars. The earth was *Jeb,* the source of earthquakes like *Poseidon* in Greek myth. And the earth was always

---

[9] See also Kegan, (1982) and my reflection on the first chapter there: Rowson, (2016).

[10] I develop this point in my book, The Moves that Matter (Bloomsbury 2019) in a section on men and women, pages 170-177.

> what was opened up and dug into, the father was dug into in order to reinsert the dead *Pharaoh* who becomes a new embryo in the sky when he ascends to become one of the stars in the body of the Great Mother thus becoming intrauterine once again. So a different valence there for the Egyptians. They like the woman on top and that's the sexual metaphor there goes right through … and they had early matrimonial traditions very strong on Goddesses and the Great Mother in that civilization.

The underlying point is there are many myths and archetypes, and the extent to which they are gendered is culturally specific. The gender question is even more vexed at the social level. How might men and women be most fully themselves, in ways truly chosen, not merely mandated, and in ways that serve everyone's interest in living what Roberto Unger calls "a larger life" – lives of greater intensity, scope, and capability? The struggle against entrenched inequalities of all kinds, including gender inequality, is secondary to that more inclusive objective (BBC, 2013).

Peterson provides useful grist to the mill here; while he walks his talk of a forthright masculinity, his solipsism and hypervigilance often make him sound clueless about gender relations more generally. When he suggested in an interview with VICE News that men and women cannot work together well because the rules are not clear, and that one of the rules should perhaps be that women cannot wear makeup at work, he sounds about half a century out of date (Mind Temple, 2018). Similarly, in an unstructured chat over a brisk lunch with several people at the RSA it emerged that Peterson strongly disliked the Disney movie *Frozen*; in essence because he thinks it is "reprehensible propaganda." He sees it as an inversion of Sleeping Beauty and believes it has a political agenda – I think relating to men not being needed – though he didn't spell that out. But *Frozen* is not merely admired but *adored* by millions. It celebrates sisterly love with the best kind of postmodern ironic twist on the familiar theme of "true love" and it includes positive male characters. I have savored watching the film several times with my sons and it strikes me as fundamentally innocent and inspiring, perhaps especially for girls grappling with social and emotional expectations. If I had to choose a single thing that makes me doubt Jordan Peterson's fundamental soundness, it is that he sees political conspiracy in *Frozen* and does not like the film as a result (Redpill Media, 2018).

More usefully, Peterson highlights that men who lack orientation become depressed, then resentful, and then dangerous, and he has drawn attention to distinctly male challenges relating to knowing our shadows; how our craving for status and purpose can lead to aggression and violence. His popularity among young men also reveals an appetite for facing up to practical challenges, starting with an injunction for which he is famous: Make your bed! Tidy your room! Perhaps men in particular are responding to this message, that meaning arises from responsibility, because that message is already evident to women.

In most couples with children, even if the father purports to parent equally, it is invariably the mother who manages most of what feminists call "the mental load": play dates, keeping track of domestic supplies or dealing with difficult feelings arising from friendships at school (Barberio, 2017). Valuing this kind of undervalued and unpaid labor, typically done by women, Kate Raworth sees as a critical feature of a viable twenty-first-century economics. Such work is also a good example of the challenge of discussing gender because of the often heard argument that women do such work more "naturally" and better than men. To state that should not risk ridicule and nor does it mean accepting the status quo as fair. The point is to move towards a clearer and wiser division of labor where effort and proclivity are recognized and properly rewarded (Maushart, 2003).

Peterson's conversation with Cathy Newman on Channel 4 is a related case in point. That discussion has been viewed over 20 million times and accentuated Peterson's fame. The debate concerned women generally being paid less than men for doing the same job, with Peterson saying that the gap is not really about gender – which he seems to view as an arbitrary variable like any other. A closer look at the data nested within gender divides reveals a range of factors including the trait "agreeableness," with women generally being more agreeable than men, and less likely to push for pay rises. This is the truth, but it's not the whole truth – and a sense of failure in converging on the whole truth is a core element of Petersonitis.

In this case, what is valued socially and culturally is not valued financially, and that's a structural problem at the heart of the pay gap. It is "structural" because the relationship between social and cultural value and financial value is set by processes mostly still controlled by men; those processes and their outcomes are relatively beneficial to men, and those outcomes arise in a world where financial value has become the predominant value, thereby perpetuating gender power imbalances.

In the Channel 4 conversation, Peterson was better armed with facts and arguments and more fully present, but the spectacle was quintessentially a debate where both sides were competing and the more nimble side "won." It was not a dialectic where both sides sought resolution through synthesis, nor a dialogue where each side sought to know an issue more deeply and fully by incorporating the perspective of the other. It was male against female, right against left, data against narrative, reason against emotion; it didn't resolve anything. It was a cultural touchstone because it was a cultural failure.

12. Prismatic

Which brings us full circle back to the experience of Petersonitis, and the question of how to improve conversations on thinkers like Peterson where allergies and infatuations are the norm. Peterson is prismatic in the sense that looking through the phenomenon opens up new vistas on this abiding issue. How should we relate to those like Peterson who on fuller inspection probably *should* evoke a both/and *and* either/or response? How do we bring about a cultural conversation where we can praise and critique without giving up on moral discernment or objective truth?

Politically speaking, that would mean a searching conversation with different premises and divergences. Men and women are different and they are the same; *and* we have to decide what kinds of gender roles are wise in myriad contexts. Capitalism is often part of the solution and part of the problem; *and yet* we need an economic model that works within social and ecological limits, so we can't continue to assume capitalism will survive in anything like its present form. Climate change is an existential threat to humanity and there is some doubt about some details in some climate models; *and* we urgently need a rapid global energy transition from fossil fuels to renewables. Democracy is increasingly an embarrassment, but it is also the noblest ideal we have; *and* we have to proactively reimagine it for a digital age. Human rights lack secure philosophical foundations and they are politically under siege, *and yet* they may be a necessary moral touchstone, worth defending not in spite of but because of their constructed and negotiated nature. Artificial intelligence creates great opportunities and is a threat to civilization; *and* the question is not how cool AI can be, but who owns it, and is what they want aligned with the greater good?

Peterson appears to have little to contribute to such conversations, which is why, although I have enjoyed the ride, I ultimately feel disappointed by him, and no longer expect to learn from him about the most important questions of our time. Some would say that his role is not to model such dialogues, but the point is that such issues are not in his purview. He is a psychologist, granted, and speaking mostly to individuals looking for direction in life. If he wants to focus on the message that individual responsibility is sacred and to use his fame and wealth to further amplify what he believes in, perhaps we should just salute his inner lobster?

But no. Given Peterson's influence, that kind of oversimplified message is precisely what keeps us trapped in outdated constructs (e.g. left and right) and oppositional identities (e.g. men and women) and militates against the generative and imaginative perspectives we need. He has the charisma, clarity, and following to add psychological and spiritual depth to our collective action problems on an ongoing basis, but shows no inclination to do so. The challenges of our time are daunting precisely because they are not principally about individuals solving discrete problems but interrelated challenges arising from collective processes. We therefore need visions of individuality that are not about slaying the dragon of the collective, but more like learning to ride it. The question for the individual is how to grow morally, cognitively, and spiritually by expanding circles of belonging, developing bio-psycho-social-spiritual selves in a manner that is truly one's own because it speaks to a social milieu in which the self is created.

Set against that fuller context and perspective, our challenge is to imagine a world beyond consumerism, where 9 billion humans can survive and thrive on a planet that is technologically imperious but ecologically imperiled and politically and spiritually confused. Peterson growls: Grow the hell up and tidy your room! Perhaps we should. Our rooms after all are dramatic settings, and microcosms of the world as a whole. But I think Peterson needs to grow the hell up too. The more profound story begins when we ask who owns the room, why there is so much stuff in it, and what joy we might find and create with the people outside.

Treatment: If neither abstinence nor denial works, try writing.

Daring of Be(com)ing Wise: Perspectives on Embodied 'Sapere Aude' En-lightened for Today

Wendelin Küpers[1]

Wise people [sapientes],
who through all the obliquities and uncertainties of human actions,
aim for eternal truth, follow roundabout ways,
because they cannot take straight ones;
and execute plans which in the long run are for the best,
as far as the nature of things allows
(Vico, 1725, SR 7)[2]

"*The function of Reason, is to promote the art of life*".
(Whitehead 1958, p. 4)

Sapere aude is often translated as 'dare to think,' especially in the sense of dare to think critically for one-self, or with a community in mind and for a different world! But sapere is not simply 'thinking', merely mentally, but closer to bodily sensing and this is making 'wise' sense, thus having an embodied sense of what is the 'fitting thing' to be done or not and how to make it happen. Therefore, sapere aude, is not merely daring to think or being cognitively critical, but more processually daring to be and to become wise. Such be(com)ing implies to give sense via coming to the senses and common sense, and making sense anew, culturally and politically as well as ecologically. Thus, living sapere aude is the be(com)ing of a living embodied and practical wisdom, embedded in, shifting and shaping to social and environmental dimensions!

---

[1] **Wendelin Küpers** is Professor of Leadership and Organization Studies at Karlshochschule International University in Karlsruhe, Germany and affiliated Professor at ICN Business School in Nancy, France. Combining a phenomenological and cross-disciplinary orientation, his research focuses on embodied, emotional and creative, as well as transformational dimensions in relation to more responsible, and sustainable forms of organising and managing. Furthermore, his research focuses on design, integrating artful and aesthetic dimensions as well as practical wisdom in leadership and organization theory and practice.
wkuepers@karlshochschule.de

[2] SR = «De nostri temporis studiorum ratione" (Vico 1709/1990). Vico (1725/1968) envisioned in his ideas about a 'poetic' (anti-Cartesian) form of knowledge (sapienza poetica) - as part of his 'Scienza Nuova' ('New Science' 2014) - a historical movement that was neither linear, nor circular, but following a spiral-like dynamics (see also Miner 1998, Strati, 2018). For Vico, wisdom has a double meaning: a 'poetic' (sense) and a philosophical or 'scientific' (intellect). Poetically, it provides intelligibility for the peoples of societies or nations and their myths that arises out of and is sustained by piety. Scientifically, as noetic knowledge, wisdom refers to contemplating concrete historicity and its human praxis cultures, customs and languages in the light of the New Science.

SOME RIGHTS RESERVED

Historically, the legacy of sapere aude as Leitmotif of wisdom traditions and 'the Enlightenment' as formative period and ongoing transformative program, was and is pervasive as many of the past and contemporary ways of thinking, values, practices and institutions of our present civilization are rooted in them.[3]

Various rationalist development and expansions of scientific discovery, technification and its applications, modern economic institutional arrangement, political and administrative reforms, state sovereignty, individual social liberations and emancipation, religious tolerations and secularization as well as democratization, nation-based and world citizenship have historically emerged from enlightened spirit, however full of variations and ambivalence.[4]

But then, what does it mean to become wise today, to live this sapere aude, enlightenment and wisdom in the 21 century, a time characterised among other phenomena, by socio-economic and political instability, worsening local and worldwide injustice and inequalities, resurging of nationalism authoritarianism. As we've seen with the recent Black Lives Matter protests, Covid-pandemic, stagnant economies and mass unemployment as well as protests all kind fires a lighting up beneath ongoing ideological battles over history and social justice.

Related to these developments, can we still sense the signs of those tremendous engaged re-evolutionary commitments that enlightened men and women, communities and collectives fought and stood for? Are those, who strived and enacted enlightened values calling us to condemn forms of neo-authoritarian rule reactionary and dogmatic orthodoxy, rigid intolerance, fearful xenophobia, and group chauvinism?

---

[3] Having partly its origin in the so-called Scientific Revolution, the Western Enlightenment, often referred to as 'The Age of Reason', eighteenth century named by French as '*le Siecle des Lumieres'*; by Germans, as 'Aufklärung'; by Italians, as 'L'Illuminismo'; by Spanish, as 'L'aIlustracion'. Interestingly, there was also an Arabic tradition which called it 'tanwir', ranging according to Kassab (2020) from Damascus to Cairo that is from Syrian-Egyptian tradition up to 19th-century, to Arab modernist movement known as the nahda (renaissance) and the withered Arab Spring recently. Historically, this age was differentiated in an Early Enlightenment (1685–1730), a High Enlightenment (1730–1780), and a Late Enlightenment (1780–1815). Only recently criticism has begun to rework the historical category of 'the Enlightenment' in terms of its geography and history, but also in terms of its historical significance, self-image, ethnocentric and racist assumptions (Peters, 2019).

[4] Graeme, (2006) studied in detail those variations and ambivalences that have gone and still go the promising rise and tragic fall and failures of the 'Enlightenment Project'. He refers to Lester Crocker (1959, 1963) for outlining how the 'philosophes' set out in search of a new foundation for ethical life, and ended up lost in an abyss of nihilism as a consequence. According to this critique philosophes failed to construct a naturalistic substitute for the religious order, not being able to bridge the nature–culture abyss and getting lost in a futile search for an universal civilisation based on reason and a rational justification for morality. According to the 'inversion thesis' the attempted implementation of Enlightened principles and ideals produces the very opposite effect to that intended, resulting in disaster. While liberal assumptions about rights, liberty and rational self-interest arose out of the Enlightenment, it also produced theories of indoctrination, of conditioning and control, which compromised them. The destructive potential at the disposal of the human appetite for power, cruelty, stupidity and hatred is now enormous and growing. In addition, the increase in individual freedom of conscience, religious expression, mobility and self-determination that the Enlightenment helped to facilitate has undermined many traditional sources of conflict while fostering others (Graeme, 2006: 1).

Today positions of counter-Enlightenment have becomes part of a more general critique of the West and its values, losing the reflexive dimension that had so long been at its core (Jung 2016: 220).For further sources and discussions concerning the 'Counter-Enlightenment' as endarkenment see footnote 10!

When we look around today we see how human and other incarnate beings are suffering from various forms of direct and structural and symbolic violence, ongoing institutionalized austerity, imperialist warfare, and religious fundamentalism, extremist terrorism, refugees crisis, nothing to say about human caused unprecedented ecological crisis, climate heating and its environmental disasters and suffering.

We are living in a time that is cast in the twilight of the 'Anthropocene Idols' (Cohen et al. 2016, Küpers, 2020), illuminating that the light of reason progressed only by co-opting fire, coal, oil, nuclear energy and the exploitative labor of many beings not blessed with the spoils of enlightenment. Can reason, especially the one of instrumental rationality, appropriated by the forces of unreasonable commercialism and wealth-craving, be made aware of that shadow side and 'debt' only when the source of light is waning, in an age of depletion and ecocidal destruction?

The related narratives range from dystopian and (post-)apocalyptic imaginaries[5] and stories of disaster, decline, demise and extinction in an eco-eschatological vision[6] to neo- and eco-modernist visions of progress, salvation and solutionist mastery. For some, the end of the world has already occurred and implying that civilization, organisms and organ-izations are already deceased and must simply begin the difficult task of adapting, with mortal humility, to this new reality. Lingering in the shadowy world of irony and difference, ugliness and horror, such a dark ecological orientation is announcing the coming climatic Armageddon or other apocalyptic framings often used as discursive-representational tactics or rhetorical strategy. For others, the Anthropocene offers a hopeful opportunity for a profound transformation via a heroic neo-Prometheusian Earth-mastery, playing with 'fire' via techno-scientific knowledge in neo-technocratic solutionist ways. Such orientation is following a hyper-accelerationist vision in which big science, geo-engineering, and big capital save both earth and earthlings or a specific problematic politics of partly illusionary hope (Küpers, 2019). These narratives are taking us either towards the edge of a personal, socio-political, economic and ecological abyss or towards promising land of saved ascendance where all problems and conflicts are or can be re-solved.

However, all these imaginaries and interpretations are in danger of foreclosing the asking of serious political questions, for example, about the possible organisational and socio-environmental trajectories of continued neo-liberal practices or of the possibility of transitioning to something even more reasonable and wise.

---

[5] Apocalyptic imagination has been described as uncovering revelation of and through the elements envisioning the imperceptible toxification and elemental dissolution of the annihilated world (Toadvine 2014).

[6] Eco-Eschatology and eco-eschatological narratives as end-of-the-world fantasies suspend the present between a geologically deep past and an indefinitely distant future. As Toadvine (2019) elaborated, our obsession with the end of the world finds expression in the form of the eco-eschatological narrative and frames speculative fiction as well as environmental prediction. Such obsession is a phantasm that reflects our desires and anxieties in the present, which leaves its mark, directly or indirectly, on our individual and collective identities, institutions, and sense of the world here and now.

Instead of seeing a storied account as a single hegemonic, linear one that is supposedly apolitical, there are multiple, debatable and polemical narratives. These storylines range from Cassandran versus Panglossian advocates to slowing-down Doomsters versus accelerating Boomsters and are thus situated as either tragic, elegiac stories with hopeless endings and the collapse of civilization or heroic, hegemonic stories of awakening.

Furthermore, our time is also characterized by 'retro-progressive' moves and neo-conservative or neo-authoritarian trajectories, including revived tribalist and populist contagion, and manifestations of personal and functional stupidities, and illiberal democracies', attacks on cosmopolitan orientations and institutions, spreading throughout Europe and the USA as well as may other countries and parts of the world. For example we might ask: Does the so called "Intellectual Dark Web" use a veneer of 'reason' and 'science' to justify prevailing inequalities economic, gender, and racial as natural, thus defending (neo-)liberalist capitalism while drawing on biology and the dreary science to bolster the status quo by depoliticising politics (Brooks, 2020)?

But there are also old and new, social movements and advocating political activism, like the environmentalist movements, anti-racial and black-rights movements, feminist movements and LGBT movements among others, All of them are manifesting a radical democratic politics of dissensus and attempting to radically, ethically and often publicly challenge existing reactionary orientation, given social norms, and, reclaimingly, who is recognized as being a competent agent to speak and shape civil life.

Why does reconsidering 'Enlightenment' may help for understanding and interpreting these developments? What would historical enlightened figures or philosophers who reflected on the role of wisdom and enlightenment tell us from their respective perspective?

Historically, the ideas of the 'Age of Enlightenment' undermine(d) the authority of the traditional aristocracy and monarchy as well as religious orthodoxies of Churches, while preparing and enacting ways for the scientific, socio-cultural political revolutions of the 18th and 19th centuries, reaching into the 20 century and today. Based and centred on regimes of reason and scientific approaches as principal sources and media of authority and legitimacy as well as knowledge[7], enlightenment functioning as a formational event established and advanced powerful ideas and ideals, and. These include among others those like freedom, progress, tolerance, fraternity, (we would today call brother- and sisterhood), constitutional government and separation of church and state, all serving as a base for civil society. In this way,

---

[7] A key idea of the Enlightenment, especially the French Enlightenment, was to learn from scientific progress how to make social progress towards an enlightened world, but the philosophes of the Enlightenment and later institutions of learning failed to generalize these methods sufficiently so as to facilitate progress in other fields of human endeavour besides science or knowledge (Maxwell 2019). According to Maxwell there is an urgent need to transform what we have inherited from the Enlightenment in order to move towards a better, wiser, more enlightened world. "Academia seeks *knowledge*, and fails to give intellectual priority to the task of helping humanity make progress towards a more civilized, enlightened world." (ibid p. 4).

Enlightenment brought cultural political 'modernization' to the West, in terms of introducing democratic values and institutions and the creation of modern, liberal democracies (Gay, 1996).[8]

Enlightenment yes, but which one: a moderate or a radical one, and how was and is it related as such with its clandestine underground to the making of modernity (Israel 2001, 2006, Jacob, 2006, Muslow 2015, 2018)?

And today? Is this present a time of an "Enlightenment NOW" (Pinker, 2018)? Or do we need understanding for how irrational conceptions of reason are harmfully defective in relation to what the traditional rationalistic Enlightenment was and is?

In particular:

– What would the mentioned and other intellectuals and lovers of wisdom (*philo-sophers*) say about why unenlightened politician and populists, extremists, including left- and right-wingers, and ideological, religious and other fundamentalist are again and increasingly influential today?

– How would they respond to the re-emerging radicalizing conservative or progressive ideologies and movements, especially neo-identitarian, alt-right shift in public spheres all over the world?

– How would Enlightenment thinkers interpret resurging of neo-authoritarian politics of power with its rhetoric and practices that are having far-reaching effects on various levels (Fielitz & Laloire, 2016).

– What do calls for an enlightened life and a wisdom-oriented citizenry[9] mean today? How is daring to know and 'be(com)ing wise' constituted by an embodied practice and co-created by a 'body-mindful' cultivation of a well-understood tasteful art(istry) of living?

---

[8] For Peter Gay (born as Peter Joachim Fröhlich) Enlightenment was the unified work of a small group of men, "the little flock," who shared liberal progressive attitudes, a critical method and mind, working for a better future, who knew and admired one another's work. According to him they shared an understanding of Enlightenment as a program of secularism, humanity and above all freedom in its many forms; it is humanity's claim to be recognized as adult, responsible beings and an Enlightened optimistic faith in social progress by the use rational principles to solve problems of social interaction.

[9] 'Civilization' although often associated solely with certain levels of technological, social, and cultural advancement, can also refer to the reflective and moral status or level of development concerning enlightenment. To be 'civilized' in this sense is to have a disposition to be concerned with civic excellence (*politikê aretê*) and virtue (*arētē*) in feelings, thoughts, competencies and action. Respect for others (*aidôs*) and a sense of justice (*dikaiosynê*) moderation or self-control (*sôphrosynê*), holiness of life or piety (*hosiotês*), and courage were among the foundation of political wisdom guiding all civic endeavors. Historically, this disposition and positioning was considered as required to live a good and successful human life and seen as the result of proper education and habituation. Moreover, the enactment of individual and collective wisdom was understood as a *form* of civilization, as the result and expression of a moral civilizing-process that comes about through the creation and transmission of interpretations of human experience and the concomitant skills to be developed (Kiefer, 2015).

Accordingly, the underlying concern of the following is to inquire into the status of an illuminating Enlightenment (Aufklärung/Erleuchtung) in relation to signs of reviving of an obscuring Endarkenment (Verfinsterung/ensombrement/nigredo),[10] including to understand an elusive '*twilightening*' as a kind of entwinement of both.

This inquiry implies the quest and question about how to rethink, reimagining and re-evaluate integrally an Enlightenment beyond traditional orientations.[11]

Correspondingly, the following asks: In which way can the call for sapere aude still mean experiencing and thinking the world and future by opening out; while we are facing the present enclosing turmoil in socio-cultural, and political cultures and dominance of non-integrative economic imperatives? And, how to respond to the challenges for transforming from an unsustainable Anthropocene towards a more sustainable wiser 'Ecoscene' (Küpers, 2020)?

---

[10] Endarkenment can be related to the tradition of 'Counter-Enlightenment' movement as part of history of ideas' that have been characterised as relativist, anti-rationalist, vitalist and organic connected to supposed proto-romantics, like Vico or Hamann (see Berlin, 1973, 2013). According to Berlin, this Counter-Enlightenment consisted of a 'family of political and moral conceptions … based on the defiant rejection of the central thesis of the Enlightenment, according to which what is true, or right, or good, or beautiful, can be shown to be valid for all men by the correct interpretation of objective methods of discovery and interpretation, open to anyone to use and verify' (Berlin, 1990: 19). As Berlin (1973: 19-20) stated: "The rejection of the central principles of the Enlightenment universality, objectivity, rationality, and the capacity to provide permanent solutions to all genuine problems of life or thought, and (not less important) accessibility of rational methods to any thinker armed with adequate powers of observation and logical thinking – occurred in various forms, conservative or liberal, reactionary or revolutionary, depending on which systematic order was being attacked…. In all cases the organisation of life by the application of rational or scientific methods, any form of regimentation or conscription of men for utilitarian ends or organised happiness, was regarded as the philistine enemy." Critics found little historical evidence for what they called Berlin's essentialist dichotomy between Enlightenment and Counter-Enlightenment as two coherent and unchanging traditions (Mali and Wokler, 2003). Overall, "modernity is inherently multiple. It comes in different blends, including Enlightened, non-Enlightened and Counter-Enlightened currents" (Lok & van Eijnatten, 2019: 415). This multiple interpretation includes for Lok and van Eijnatten also a global Counter-Enlightenment that is existing in different times and places. "The Enlightened, liberal, progressive modernity so widely applauded as the way upwards and forwards had failed to deliver; it could never deliver because it was unable to meet the deepest spiritual needs and time-tested values of mankind, the principles, tenets, customs and ethical precepts embedded in age-old civilizations…" (ibid 417). There has been a 'flight from reason' manifesting in dark and occult counter-rmovements to enlightenment (Webb 1971, 1976, 2009). Eeven efforts to eradicate the irrational appear as being themselves irrational, and often manifesting a disclosure in time of foreclosure (Smith, 2019). There was a rationality of irrationality in connection to enthusiasm especially in late enlightenment (Conrad, 2008). See also Nick Land's 'The Dark Enlightenment', that – as part of accelerationism – opposes egalitarianism, incorporates explicitly racist views and is sometimes associated with the alt-right or other right-wing movements. http://www.thedarkenlightenment.com/the-dark-enlightenment-bynick-land/ Millgrams (2015) sees a great endarkenment related to our age of hyperspecialization and entrenched in disciplinary conformity. Scholars and their scientific work are becoming more narrow, self-contained, and disintegrated as they don't know and don't care about anything other than their own tiny field, reviewing each other's papers and training each other's students to behave in the same fashion. All this results into deterioration of creative, integrated, systemic and critical thinking in the academic world, a corruption of scientific integrity by a slow, degenerative process of endarkening. Nikos Kazantzakis: "The real meaning of enlightenment is to gaze with undimmed eyes on all darkness."

[11] For example those that take light as a major metaphysical symbol, equating with spirit and its manifestation as intellect, virtue, morality, healing both physical and spiritual, and other positive set values or traditional political orientations like socialist versus liberalist worldviews.

For responding to all these quests and questions as well as diving in an uplifting way deeper into the reasons and responses to the current state of affairs and actual and acute developments, it makes sense to learn from different positions or contentious perspectives and connecting them to our times and futures to come.

In order to explore the same, the following invites you, dear reader, in the form of an alternative textual/contextual narrative practice, first to a thought experiment and then to enter a multi-layered dia- or metalogue.[12]

---

[12] Rather than constructing separate, fixed or closed individual-based definitions of realities or rational-lines of argument, such poly-logical practice of a metalogue (see Bateson 1972; Bateson & Bateson, 1988) open up to a living relationality and possibilities of a spiraling, disclosing and co-emerging flows. Polyphonic voices, individually and interwoven in an arguing chorus as a kind of aesthetics of (re-) presentation. Such presentational practices uncover and allow other modes of communication, including felt sensitivities, imaginative sounds, visual associations etc. Accordingly, such dia- and/or poly-loguing is opening for a poly-sensuous interplaying of tasted, gestured, and viewed expressions thus multi-voiced con-versation that is a living narrative, which includes a diversity of points of standing and moving. Not aiming for a single vision or finalizable version, these inter-exchanges are an array of juxta-positioning reasons for or concerns about and perspectives on various angles. In terms of epistemology, this implies that if there is any truth to be found or better to say co-created, it happens through a multitude of simultaneous expressions with their quests and questions, engagements and commitments. This kind of heteroglossia can help to question, test and contest our own and others' ideas, those established and those merging or to be developed. It is through the plurality of our consciousness, inter-relationships and hybridised negotiations that the potential can be actualized or "actuated." In particular, these are possibilities of 'trans-individualistic', post-entitative and more integral understandings of and repertoires for creative interpretations and enactments. As a writing modality, this form, much like a sounding board opens up for complexity, ambiguity, and emotional resonance. Such resonance comes from making the words – for lack of a better word – embody what they are about and make them breathe experience. Hopefully, the listening reader can relate to those or invoke in them likewise sensory experiences that may lead to a more nuanced understanding, and invite them to extend the text, or relate to their life-worldly con-texts. By practicing a dialogue as a "discipline of collective inquiry" (Isaacs, 1996) or co-inquiry (Heron, 1996), you the reader(s) are thus invited to open-up to discover or co-create inter-pretations of what appears as "real", relevant or insightful. Listening to multiple voices, incarnated in presences of different persons and propelled contents, allows participatory witnessing an embodied relational logic and enacting an inter-practice in praxis that is sensitive for the oblique, meanings *between* lines and alluded hints, revealing other ways of being and becoming. As active audience or engaged readers of this concert of voices, we are becoming listeners, and perhaps are provoked to comments or to ask possible questions, state contestations or find other forms to contribute with our own ideas. This can lead to further weaving the con-textures or advancing the ongoing, unfolding fluid dis-courses to emerge. Please feel invited to share your responses, reflections or imaginations by writing, dabbling, drawing or expressing them and, if you like, forward them to the author for co-creating a hyper-contextual repository: mail@wendelinkuepers.eu. The idea is to set up a web forum or blogging space on-line, where all comments will be gathered, as a forwarding feedback and continuation of an ongoing inter-involving conversation…

Imagine enlightened men, who meet, and are having conversations about events in 21 century and the status actual en-darkening reality and still potential ‘en-lightening’ wisdom therein. The chosen personalities – representing selectively different and contested positions – in the following are Horace, Kant, Nietzsche, Foucault, Habermas and Merleau-Ponty and some more. This conversation does not include Aristotle and only implicitly refers to the Aristotelian tradition of phrónêtic wisdom (see Küpers 2013), nor indigenous and non-Western wisdom traditions in poly-cultural world (see Intezari, et al. 2020).

The first one, Horace was an antique Roman poet, then Kant, who was *the* philosopher of Enlightenment and the post-Enlightenment philosopher Nietzsche as well as then also Foucault as post-structuralist/postmodern scholar, focusing on power and conflict and Habermas as representative of the unfinished project of modernity as well as finally Merleau-Ponty as post-Cartesian philosopher of the body and embodiment.

You might ask: What do these so unalike personalities with their very different ways of feeling, thinking, speaking and writings in quite different languages[13] have in common?[14] Well, they all have thought about the role of reason and wisdom in and for their time and beyond. Correspondingly, they have all written programmatic essays that are calling and processing the status of enlightenment and daring to know, respectively to become wise![15] Some of these voices and reports may appear as hopelessly outdated historical accounts, others may appear as revealing in being revisited others promising or providing inspiration for us today and a future to come….

---

[13] Just a word on words and language: The conversation you are going to listen to uses English as ‘lingua franca’. For many of those who speak here this is not their mother tongue. Using another language and any language at all is, at one and the same time, enabling and limiting, liberating from the confines of our own spoken tongues and restrictive and constraining by using a foreign lexicon and its loss of subtleties and cultural qualities in translation. Speaking about translation, another related challenge concerns the transference of ideas of distant and different times and contexts to our world today and for a future to come. All what was presented here, all the expressions of representations were done in ways the author understood and understands them provisionally, informed and related to the world arounds him. Correspondingly, the same might be true for you as a reader who interprets and uses in your own ways. Overall, while questioning an unreflexive use and hegemony of English in academic practices, what would be wise!, is to become more imaginative, inventive and experimental in performing multilingual forms of expressions (Steyaert & Janssens, 2013), and making the multiplicity and linguistic repertoires involved visible or hearable, moving towards a Cosmopolitan *Multilingual Franca* approach (Janssens & Steyaert, 2017).

[14] As these authors and their writings manifest, the courage to use reason and wisdom as well as the project of enlightenment are not unified on a single set of doctrines, but serve a diverse set of ends, a pluralized interpretation – ranging from cosmopolitan ’radical’ enlightenment to various, more conservative, national enlightenments (Israel, 2001) – as well as Enlightenment as transfiguration (*Verklärung*) of reason and also Counter-Enlightenment (Mali & Wokler, 2003). However the unrestricted definition of Enlightenment, or its alternative, the admission that there were multiple Enlightenments, has rendered the subject so blurred and indeterminate that it is impossible to reach any assessment of its historical significance (Robertson, 2003: 82). With Robertson, the Enlightenment for which a case is made here is one, which existed as historical phenomena, rather than an artificial philosophical construct. It is not an Enlightenment which can be held directly responsible for the horrors, any more than for the advances, of the twentieth and twenty-first centuries; far too much history lies in between. But as a specific intellectual movement of the eighteenth century, it is an Enlightenment which can be matched against the conditions which faced it in its own time. (ibid, p. 82). Accordingly, Robertson (2003) proposed that the intellectual content of the Enlightenment is to be found in its “commitment to understanding, and hence to advancing, the causes and conditions of human betterment in this world” (ibid, p. 78). He emphasized the following three concerns as central to the Enlightenment’s efforts to understand the causes and conditions of human betterment: (a) the systematic study of human nature; (b) inquiries into the causes of “material betterment, the subject matter of political economy”; and (c) more

Let us enter and 'zoom' into the symposium and listen to the ongoing conversations of this meeting of embodied minds as a co-inquiring process of various con-verging but also diverging stances and dialectical dances.

Stage: The "dramatis personæ" are gathering at a round table in a beautiful room with natural light, and a view to the cultivated and wild nature around, designed for having such a symposium. There is an ongoing informal conversation, as some of the participants know each other, while others are introducing each other, and again some are casting suspicious glances or remain in silence. Some refreshing drinks and light food are offered, and an overall relaxed atmosphere pervades the gathering.

After some time, the facilitator rings a mindfulness bell and as the participants have found their place he commences speaking:

Facilitator: Welcome everybody to this symposium! We have gathered here for a conversation about what 'sapere aude,' daring to know and becoming wise, meant in the past and may mean today and a future to come. This gathering aspires to revisit and reflect critically the meaning of 'Enlightenment' in and for a time in which enlightening orientations seem to be overshadowed by various forms of a multiple crisis and unwise realities, economically, socio-culturally, politically.

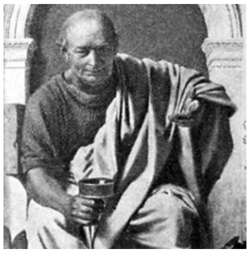
First, I would like to thank you all for that you have accepted the invitation for what promises to become an extra-ordinary event. Timely, we will move through time, chronologically but also throughout with links to the present. Furthermore, an interjecting observer is guiding us and I as a facilitator will try to moderate the discussion.

Salve Horace, can I ask you as pioneering thinker who coined the term, to share your understanding of sapere aude and its context and also why its practice, thus wisdom seems to be not present or event lost in our crisis-driven time today? What would you recommend to us today?

---

general investigations, beyond the more specific concerns of political economy, with the historical progress of society "from 'barbarism' to 'refinement' or 'civilization'" (ibid p. 78). Enlightenment was an actual historically situated enlightening activity, especially; the framing of sciences of human nature, political economy, and a historical development, but also a construct relevant for us and a future to come.

[15] *Sapere aude"* (Horaz/Horatius, 20 BC/ Epistulae 1,2,40)
„Beantwortung der Frage: Was ist Aufklärung" /
"Answering the Question: What Is Enlightenment?" (Kant, 1784, 1999),
"Qu'est-ce *que la critique? / "What is Critique?"* (Foucault, 1978, 2007),
"Qu'est-ce que les Lumières?"/ "What is Enlightenment?" (Foucault, 1984, 1997),
"Theory of Communicative Action" & "The Philosophical Discourse of Modernity" (Habermas, 1990)



Horace: *Gratias vobis ago*, for the invitation here! Dear wisdom-loving friends (*philosophoi*), as you know, I have been concerned for the public welfare and the need for returning to early Roman standards of morality after those cruel periods of bloody decadence, that I experienced. And it is not only me, as I am speaking and echoing the aspirations of a war-weary society at large. Accordingly, I warn you not to fall into a retro-regressive, degenerative and even decadent state-of-affairs, characterized by intrigue, conspiracy, demagoguery, and vain and fierce ambitions and bloody civil unrest …

You ask: Why is there not more reasonable processing and acting in accordance with reason (*akrasia*), when facing the challenges of your crisis today? Well, you know your situation reminds me of what I experienced during my life in late-Roman time with its paralysing politics. In that context, I called for daring to know and to begin again. For me to begin is already to be halfway. Get your-self going with efforts and properly being underway is what matters. Dare to know, begin! And dare to begin is to know qualified as daring to become wise! How to do so? Well with elegance in simplicity (*simplex munditis*) and perhaps sometimes even being nobly untruthful (*splendide mendax*).

But never forget: *carpe diem*: be in and enjoy the moment, thus make the best use of your day and night. This focus on the now does not mean to ignore the future. Rather it is not to trust that everything is going to fall into place for you, but that you need taking action for the coming. In other words, be mindfully present and to cultivate what is called a *Stoic and Epicurean* sentiment and practice!

Stoics: Yes, using one's mind to understand and resonate with the natural world helps accepting the moment as it presents itself. But for us, all this means not allowing oneself to be controlled by the desires for pleasure, nor the fear of pain. Against your misinterpretation of our approach today, being wise for us does not seek to extinguish emotions and passions of anguish or suffering. Rather, we need to liberate ourselves from and transform what affects us - what you may call sublimate – by resolute exercises (*askesis*) of self-discipline. And this needs to be employed by methods of logic and reflection that enable developing clear judgment and inner calm….

Epictetus: This helps to realise that not things, but opinions about things, trouble you and all men. Test and assess all impressions by asking yourself: 'Is this something that is, or is not, in my control?' And if it's not one of the things that you control, be ready to realise: 'Then it's none of my concern.' Review then your emotional responses, for example. What made you angry? What nagging fear continues to wear at you? To whom do you have antipathy? What other negative emotions are you experiencing and why? To what inappropriate impression have you assented? What form of being virtuous and virtuoso have you lacked to respond impulsively and to allow this disharmony into your "inner citadel"? Thus, take a moment and deep breath before responding, preserve your serenity and remain above the fray.

Stoics: Thereby, we can maintain equanimity in the face of life's highs and lows as well as to cultivate modesty. Thus, this self-mastery is not about repressing feelings, but about becoming emotionally resilient to misfortune and having *eu-pathos* and perpetual tranquillity, while being one with the workings of nature and fate as well as the cycles of existences and the divine orders of the pulsating universes. Thereby you can cope with any tragedies and all suffering and cultivate a life of *eudemonia***.**

Facilitator: So it is all about learning to think clearly, consistently and see things as they really are in a controlled way. Then we can make good choices from smallest everyday actions - including those about where to focus our time and energy - to the biggest decisions of your life? As much as I understand your humble program of being happy with what you have, but how do you find a sense of inner peace, while also dealing with other people not with anger but with compassion and in a democratic way.

Hierocles: One must consider that, in a certain way, one's brothers are parts of oneself, just as my eyes are parts of me and so too my legs and hands and the rest.

Stoic Zeno: Let us gather under the shade of the Stoa porch (*poikile*) in the public space (Socrates: or market place) of our polis, where anyone can listen and join in the debate. For us certain and true knowledge (*episteme*), can be attained only by verifying the conviction with the expertise of one's peers and the collective judgment of humankind. And for us striving to become citizen of the world external differences such as rank and wealth are of no importance in our social relationships.

Diogenes: In this sense, I am also a *kosmopolitês* as that is where I come from …

Stoics: To get a more objective perspective, it's helpful to take a step back and view an issue as if you were a disinterested, but sympathetic, 3rd party. Importantly, our stoicism is not a religion, but is compatible with different faiths and religious traditions. There is room for different interpretations and different levels of philosophical commitment.

Seneca: Organise your Self, including knowing your strengths and weaknesses, handling your negative emotions while maintaining spaces to form reasoned responses and considering what you would call in your time now contingency planning, and repurposing!

Irvine: Mastering one's self is being engaged in the only moment where we exist, this one, while trying to understand the ways things are and living modestly, that is program of a good life via an 'Art of stoic joy' (2009).

Epicure: Indeed, we need to gain knowledge of the workings of the world, while we limit our desires in a simple life to attain a state of tranquillity and freedom from disturbance, or imperturbability (*ataraxia*) as well as freedom from fear as well as an absence of bodily pain (aponia), independence (*autarkeia*), good disposition (*euthumia*) and so forth… Apropos ’joy’: But what is also important indeed is to cultivate the presence of intrinsic pleasure without denying its life-enhancing qualities.

> *Voice from off-stage* **Marx**: Epicurus is the ‘greatest representative of the Greek enlightenment’ as I have shown in my dissertation on the difference between the Democritean and Epicurean Philosophy of Nature.

Lucretius: *nodding in agreement* Yes, how essential are those quiet, long-lasting and never cloying pleasures and the appreciation of embraced natural beauty gained by contemplative pursuits in the spirit of the wise Epicurus. This even more in those times of violent civil wars, political assassinations, massacres, revolts, conspiracies, mass executions, and social and economic chaos, a world of anxiety and turmoil that I have experienced with cities decayed, trade declined, and an anxious populace scanned the horizon for barbarian armies.

My life has taught me – as expressed in my book ‘On the Nature of Things’ – that there is no hope of bribing or appeasing the gods, no place for religious fanaticism, no call for ascetic self-denial, no justification for dreams of limitless power or perfect security, no rationale for wars of conquest or self-aggrandizement. And for you urgently to relearn is also that there is no reason to set humans apart from other animals thus that there is and cannot be a triumphing over nature. Rather, human beings should conquer their fears, accept the fact that they themselves and all the things they encounter are transitory.

Seneca and Montaigne: That is another reason why a wise life is learning to die!

Lucretius: … and embrace the refined phenomenal qualities and the pleasures of this incarnation in this very material world.[16]

Interjecting voice from contemporary time

Roy Scranton: Today now it is learning to die not as individuals, but as a civilization. in the dire so-called Anthropocene as that period of a large-scale die-off in the biosphere and global ecological collapse that’s already well underway, caused by and ending the global capitalist civilization as we know it, within decades and the possible extinction of the human and other species within centuries. But there is a New Enlightenment possible: Through interrupting social circuits of fear and reaction, looking deep into the face of death, and open up a human relationship to the universe in which we might live not as parasitic consumers, but as co-creators —a relationship in which we might learn to live as the very light from which all our power ultimately flows. Our future will depend on our ability to confront it not with panic, outrage, or denial, but with patience, reflection, and love (2016).

---

[16] **Bergson:** Lucretius you are not only a genial poet, but also an inspired and singularly original thinker. We need to see the world sub specie durationis, i.e., as enduring (see Ansell-Pearson, 2018).
Santayana: I praise you Lucretius as true creator of scientific materialism and the real founder of Epicureanism. Certainly in an Orphic spirit sings Hoelderlin; “For we are a conversation and have been able to hear from one another…”. Has humanity learned; but soon [we] will be song!” “Seit ein Gespräch wir sind und hören von einander, Erfahren der Mensch; bald sind [wir] aber Gesang” (Hölderlin, 1975–2008, FHA VIII, 643).

Epicureans: We need the higher art of life! Cultivating an art of living in our sense is the opposite of what is connoted to our philosophy, misunderstood as a self-indulgent hedonistic, luxurious pleasure-seeking affair. On the contrary, to such superficial life, daring to know and pursuing a serene elevation of refined sensual and intellectual pleasures and a tranquillity of body and mind constitute a flourishing happiness in its highest form.

Epicur: Indeed: it is better to abstain from coarse or trivial pleasures if they prevent our enjoyment of richer, more satisfying ones…And this all is best celebrated in a beautiful garden with a circle of friends, being open to both slaves and women as part of a community for joint philosophising, but also growing our own food: going against the mores of the time!

Why with friends? Well because of all the things which wisdom has contrived that contribute to a blessed life; none is more important, and more fruitful, than genuine friendship. In such circle of friends everyone can self-improve, experience mutual admonition and gentle correction in the ethos of goodwill, respect, frankness, and gratitude as well as with an openness and moderation in all things.

For this kind of life, we have to shun politics and public affairs because it could lead to frustrations and ambitions, including lust for power or a desire for vain fame, all in vain. Please hear me well: ‘do not get involved in political life’! Such undertakings cause mental disquiet and disturbance and thus can directly conflict with our epicurean pursuit for peace of mind and eudaimonia as well as lived virtues. Only indirectly by our alternative ways of organising communities, promoting practices – such as justice, friendship, and economic co-operation – that are genuinely useful to people’s needs and eliminating all that promotes false conceptions of values and places our happiness in danger we may inspire others to create their ways of life and modes of virtuous communities or societies.

Christian Theologian and Priest: Speaking about virtues, reinterpreted in religious form and opposed to vice, our theology provided an explanation for the chaos of the Dark Ages. And we, with help of our almighty God, know the way back into light, provided only by the church. For us, human beings are by nature corrupt, sinful inheritors of Adam and Eve, and therefore deserve every miserable catastrophe that befell them. God cared about human beings, just as a father cared about his wayward children, and the sign of that care was anger. It is only through pain and punishment and even then only some pious faithful believers in Christ as the incarnation of God, the creator can find the narrow gate to salvation and see the divine light. Augustine: Again it is our Christian doctrine of salvation and damnation that offers human existence hope for an eternal happiness out of the misery and suffering of the ‘interim’ world.

Petrarch: No, I do not need you priest and dogmatic lessons. I experienced delight and found enlightenment on Mont Ventoux that I climbed for pleasure alone and could return then descending to the valley of the soul with my inward eye upon myself. Afterwards I could then travel on as an international scholar and singing poet-diplomat, retreating to contemplate on enlightenment of humanism that was than mediating the flowering of what you call Renaissance, the re-birth of the lift of antiquity.

Observer: Now we have listened to representatives from ancient times. We learned about the difference between Stoic focus on cultivating life, advocating debate in public spheres and becoming cosmo-political versus Epicurean exercises or '*askesis'* of refining private pleasures with friends, while shunning politics as well aas various tensions between religious and secular orientations!

Hadot: We need to revive the existential dimension of (ancient) philosophy today as therapeutic, transformative way of life (*manière de vivre*!). Let us rescue the synthetic nature of wisdom by which practical skill, rational knowledge, political acumen, artistic expertise and mystical experience are different facets of the same! I'm very much convinced that it is possible for modern man to live, not as a sage (*sophos*), but as a practitioner of the ever-fragile exercise of wisdom (1995, 211). But he needs relearning recognizing imaginatively himself as all things in a perpetual state of transformation or metamorphosis, while being part of the Whole and elevating to cosmic consciousness, thinking and acting in a universal perspective.[17]

Observer: Next, we will listen into a continuation and furthering of discourses in 'modern times' where the advocacy of a reason-based Enlightenment is voiced by Kant that in turn is provoking a radical critique and counter-orientation expressed by Nietzsche.

Kant: Dear Horace and Stoic, respectively Epicurean friends! I still resonate with some of your orientation and agree with your intentional thrust, but cannot accept your positions that appear to me as outdated approaches as well as the forms of operation you suggest and status of reason you presuppose!

---

[17] The absence cosmos and cosmic Whole (and considering the underlying mysticism) and the other in the technologies of the (politically) caring relational understood self in Foucault and the insufficiency of his program of an aesthetics of existence as an ethical model for the present as well as some of his philological deficits, e.g. a mistaken emphasis on pleasure, are reasons why Hadot criticized him (But see: Testa 2020). Hadot argues that two broad attitudes have dominated our understanding of nature over the millennia, each of them with a god to represent it. The first is the Promethean, the second the Orphic. The first Promethean one is voluntarist and grasping, seeking to impose cultural forms on nature the better to understand and control it and this conception shows up in the history of both magic and mechanics. The second Orphic one, by contrast, is essentially cautious and as perspective is more aesthetic, contemplative and disinterested compared to the Promethean. Unlike the latter, it seeks out and is content to abide in nature's irreducible mystery and wildness. Both approaches, says Hadot, have as their goal the defense of humanity's "vital interests" (Hadot 2006: 317).

I am using your motto *sapere aude* in my answering of the quest and question of what Enlightenment is, responding to a critical inquiry by a master free-mason, namely: „Was ist Aufklärung?“ (1783). Importantly, this Aufklärung does not only characterize the period of my lifetime. As was the spirit of the time, the *Zeitgeist*, I am designating ‘Aufklärung’ as something each reasonable man can pursuit, rather than merely an age in which one is living. You know ‘*aufklären’* literally means to illuminate and to clear up. Accordingly, I am using this – itself wise – leitmotif for developing my theories of the application of Reason – yes written with capital letters – in the public sphere of all human affairs.

Facilitator: What does Enlightenment mean for you then?

Kant: For me, Enlightenment is man's departure and emergence from his self-incurred immaturity. Immaturity is the inability to use one's own understanding without another's guidance (Kant, 1996: 58), The German word for immaturity, ‘Unmündigkeit’ means not having attained age of majority or legal adulthood. ‘Unmündig’ also means dependent or unfree, and another translation is tutelage or ‘non-age’ (the condition of not [being] of age). My moral philosophy is centred on the concept of autonomy, and here I distinguish between a person who is intellectually autonomous and one who keeps himself in an intellectually heteronomous, i.e., dependent and immature status. And this very unenlightened immaturity is self-imposed if its cause lies not in lack of knowledge and understanding, but lack of resolve and indecision, and thus lack of courage to use one's own mind and reasoning without another's guidance.

Facilitator: What is needed beyond courage and determination?

Kant: Enlightenment not only requires courage! What is needed is ‘orientation in thinking’ and giving direction of thought that is to reflect on what basis does our thought path determine the way we act.

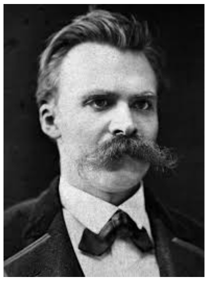
Cassirer: Indeed enlightenment is a ‘*Denkform’* a form of thought/reason (1951, Renz 2020)!

Kant: Thus, we need to enquire into the conditions necessary for the possibility of knowledge as well as morality and wisdom. Likewise, what is called for are institutional changes and a corresponding ‘carrying’ machinery and institutions, like my envisioned cosmopolitical League of Nations, or ‘*Völkerbund’*, which became the United Nation![18]

So you see: The Enlightenment program is a universal one of rationality, equality and practical morality as well as inner autonomy and political authority, all based on private and public use of reasoning, preparing eternal peace.

---

[18] In my essay ‘Perpetual Peace’ (1795, 2016), I proposed a peace program to be implemented by governments while demanding a commitment between states and organizing peace (as teleological goal of history) as contract by following these principles: “The civil constitution of each state shall be republican” and “The law of nations shall be founded on a federation of free states” as well as that “The rights of men, as citizens of the world, shall be limited to the conditions of universal hospitality” (*ius cosmopoliticum*).



Nietzsche: And it is that very spirit of Aufklärung that is an essential step into decline, ending in passive nihilism, starting with the French Revolution, *Aufstand* a rebellion of slaves, a victory of egalitarianism of the weak. What we need is re-evaluative transformation of all values. And it is the will towards power as driving force that deconstructs existing values and raises itself as highest value. With the passing of the old moral, after the remaining death of God and Gods killed by us and our Enlightenment! (A greatness of a deed perhaps too great for us?), we need to give a different meaning, thus to lay a new significance into what became meaningless.

Your rationality-based enlightenment appears to me as an arrogant intellectual ethos that made troubling universal assertions about the nature of human existence, knowledge and society. The pious faith of Descartes, and his doubtful belief in rational autonomy, the revolutionary fantasist and moral fanatic Rousseau and his social contract and egalitarian politics of general will, you Kant, misunderstood reason, categorical imperative and universalistic morality as well as secularised subterranean Christianity in your values, but also Mills utilitarianism and ideas about freedom and later then the beliefs of Darwin and Spencer an others in progress, I have a disgust for the demagogic traps for these ideas of 'enlightenment' for being cosy and for their plebeian familiarity.

Facilitator: What do you think about the philosophical base of Enlightenment and in particular the reasonable autonomous self?

Nietzsche: All those claims of Cartesian and Kantian metaphysics and epistemologies cannot hold. Cogito is after all only a word, a grammatical custom and its use a linguistic trick. You see, the Cartesian method of universal doubt and Kantian quasi-theological prejudices of reinvented fictions of transcendental ideals for justifying a moral scheme, are all based on an unconscious dogmatism. All of them are actually an impediment to knowledge and opposed to life, precluding a joyous science and perspectivist approach. We need an autonomy beyond good and evil, defined not in terms of moral laws, but in terms of character and nobility, enacting a creative will that engenders the new that transgresses reason itself.

Facilitator: On what do you how lay the foundation for wisdom that can serve us well also in the 21 century?

Nietzsche: For me, before all, it is the Leib (Body) is the great reason and wisdom. And this very ‘bodied’ reason becomes a function of the other, the a-rational, as part of an intensified life. I tell you, there is more sagacity in thy body than in thy best knowledge. Again, in the corporeal is a real and great sagacity, a plurality with one sense... Behind your thoughts and feelings, my brothers, there stands a mighty ruler, an unknown sage, whose name is self. In your body s/he dwells; s/he is your body.

Kant: No, not the irrational body, but the Reason – yes with capital letter – is the source of all knowledge and wisdom! We need to keep reason 'pure' from merely contingent bodily and social influences, It the reason-based Enlightenment that liberates us from passions and from authority and authoritarianism by making use of our rationality and knowledge that can be understood by others, who are equally rational beings, thus open the possibility for universalisation.[19]

Facilitator: Why then, do unenlightened politician and populists as well as extremists and neo authoritarian regimes find such influential followership in our contemporary world?

Kant: Perhaps for similar reasons as the avaricious Sophists with their specious and rhetorical practice using also fallacious and deceptive arguments gained currency before in Greek and Roman times. I do not think, like the elitist Plato seems to be inclined that it is because people were and are too stupid to see through them. Rather, the sophists had been influential and 'successful', because they met with the expectations that a majority of debarred and frustrated people had, with regard to the needs and wishes they wanted to be fulfilled.

Likewise, radical forms of doubting scepticism that deny that knowledge or rational belief is possible feed into populist power, although I learned a lot from the mitigated scepticism by Hume. While he was right to claim that we cannot strictly *know* any of the existence of God, the soul, free will, etc. our moral experience entitles us to believe in them.

Facilitator: What about ordinary humans? How can moral philosophy help for our behaviour? What power has Aufklärung for humanity today?

Kant: Admittedly, as an academic, I was tempted to be sceptical about the abilities of 'ordinary' human beings, but reading Rousseau had taught me that morality was not the exclusive field of expertise of philosophers. Human beings act morally quite independently of philosophers' thinking about it. What moral philosophy can do is help to achieve clarity about what motivates us in our moral behaviour and can give us reasons and confidence. This is what the critical method is designed to do in the field of ethics and beyond, as I develop in the *Critique of Pure and Practical Reason and Critique of Judgement*![20] And I discussed with my friends that Aufklärung carries the power to make humanity more mature, also today.

---

[19] **Gerhardt:** As important as it is to take the departure of the body, there is the need for moving beyond the same and developing the organisation of reason which enables also a social connection through mutual communication and evaluation out of an individual-including, liberal, but ultimately public consciousness *("homo publicus").* And as "*animal sociale sive rationale*" humans have the ability to rule themselves normatively, thus to act according to reasons that have to be justified factually and societally. Yes he can play, say not and create! "*homo ludens, homo negans et homo creator*" (2019).

Facilitator: Would you say that we are living in an actual or potentially enlightened age?

Kant: Again, my and your age was and is one of enlightenment, by which a process of emancipation has become possible – in my days also because of the enlightened monarch King Frederick, who you call 'the Great'. But, I concede, it is not an enlightened age yet. Nevertheless, I am convinced that the progress towards a full Enlightenment is humankind's final coming of age, the cultivation of the human consciousness from an immature and dogmatic state of ignorance is our future! But affect and passion shut out the sovereignty of reason and no human being wishes to have passion, for who wants to have himself put in chains when he can be free?

---

[20] While the first one focusing on 'Theoretical Reason' was dealing with questions concerning the foundations and extent of human knowledge, thus a critique of the pretensions of pure theoretical reason to attain metaphysical truths beyond the ken of applied theoretical reason. The conclusion was that pure theoretical reason must be restrained, because it produces confused arguments when applied outside of its appropriate sphere. The second one of 'Practical Reason' defended that (theoretical) reason is capable of grounding behavior superior to that grounded by desire-based practical reasoning, thus is actually a critique, of pretensions of applied practical reason. Practical reason is the faculty for determining the will, which operates by applying a general principle of action to one's particular situation. And here wisdom in particular is concerned with the practical end of humans' existence on earth. (see also Rowley & Slack, 2009). Pure practical reason – as opposite of impure or sensibly determined practical reason – that drives actions that are good in themselves without any sense dependent incentives, must not be restrained, in fact, but cultivated. Thus, how can the principles of practical reason be brought to bear on real life (via moral education) how can we make people live and act morally. Reason, common to all human beings, must be properly controlled: Reason itself is not an unqualified good but must be employed critically to lead to moral principles. Likewise, people can understand the moral law without the aid of organised religion. There is an inherent tension between morality and religion because there is a danger that people may act morally not because it is the right thing to do but because their religion prescribes it. This would take away the value of a good act: I am convinced that we can do the right thing for the wrong reasons, which would be devoid of moral merit. Achieving desirable outcomes is not enough; moral merit lies in the right intentions that are freely willed. Freedom is the necessary ground for the existence of the moral law. In my '*Critique of Practical Reason*,' I elaborate on ideas about how moral judgements can be made. A maxim, a moral belief, must stand the test of the 'categorical imperative' before it can become a moral law. Moral laws are not contingent, they are not 'hypothetical' imperatives, but universal principles, 'categorical' imperatives. Pure reason fails in the area of knowledge but comes into its own in the area of moral judgements. We can rationally figure out what to do by identifying the principle – of praxis - that lies behind a proposed course of action: What do I commit myself to by doing x? Next, we need to find out whether the principle can be a categorical imperative by asking ourselves if we could will it to be a universal law, as unbreakable as a natural law. The categorical imperative is strongly bound up with a belief in the dignity of the human individual (and 'Perpetual Peace' for human kind). It would be absurd to deny that all human beings are moral lawgivers, and as such merit our respect. It is therefore rational to treat them accordingly, i.e. never to simply use others for our own ends but to respect that they too have ends. In philosophy we are interested in three great questions: *"What can I know?", "What should I do?" and "What may I hope?"* These three, however, can be subsumed under one great question: "*What is a human being?"* If making a contribution to this project is the aim of all philosophising, we must go further than talking only about knowledge and ethics. Therefore, I wrote a third *Critique**, the** Critique of Judgement**,*** being concerned with the areas of aesthetics and religion. After all, the question of the human being would be very inadequately answered if we didn't for instance examine the fact that we can appreciate things from an aesthetic point of view.

Nietzsche: As much as I share to a certain attach your attack on superstition, religious dogmatism, outmoded forms of governance and resonate with some of your ideas of liberation (/in my middle period (late-1870s to early 1880s), your disembodied life-alienating Aufklärung will never be the one I call for to be enacted experimentally and artfully by an avant-garde of free spirits!

A life without genuine passions, life is rigidified and the world reduced to simply 'quantity and line and law and nonsense. And if this is all that existed, life would be turned into something strictly mechanical, automatic, predictable, regular, and even boring. We need learn loving, elevating, gilding, cultivating, sublimating and singing our passions, transmuting passions (*Leidenschaften*) into joys (*Freudenschaften*)! Instead of obedience for predetermined ventures, other-worldly escape, or metaphysically defined purity, we need free adventures towards the indefinite, this-worldly exploration, allowing the discovery of the alloyed and the possible!

Nietzsche getting up and moving, while shaking head, shivering with his body, leaving the room for traveling to the 'de-lightful' South…calling back with the voice of Zarathustra:

Nietzsche: All your pseudo-enlightening morality and moralising are oppressive, punitive, and a normalizing force, prisoning genuine life and living. This moralism is a weapon of the weak 'serving' the decadent people and their apathetic superstitions with all their *Ressentiment* of being the last men of this nihilistic age unable to build and act upon a self-actualized ethos!

Facilitator: What is truth and what to live for then?

Nietzsche: The truth to live for is one of the new *Übermenschen*, the overcoming man, who is more than human and who remains faithful to the earth. Once again: The human is something that must be overcome: and for that reason you must love your virtues as being themselves sub-limated – i.e. rising to a limit or upper threshold – transfigured passions and expression of your unique self-cultivated character dedicated to overcoming as practice of wisdom – for you will perish by them.

Hear this naked truth: And you wise and knowing ones, you would flee from the solar-glow of the wisdom in which the overman joyfully bathes his nakedness and then walks and dances with light feet and in a non-fanatical mode beyond human, all too human, unintelligent good and evil! Let us – like incarnated in Epicurus who has been alive in all ages and lives now, allow wisdom to assume bodily form (as I outlined in 'Human All too Human' II 224) a poiesis that enables the individual to negotiate and affirm the most demanding and challenging questions of existence! Overall: The secret of realizing the greatest fruitfulness and the greatest enjoyment of existence is to live dangerously!

Lewis Call: *shouting back to him in a post-anarchist voice:* The irony of your relationship Nietzsche with the Enlightenment, is that despite your virulent and profound critique of its rationality, its misunderstanding of the individual, its politics and its science and moral schemes, you retained its faith in progress and its desire to construct a better world, thus an utopian project that retained enlightened ideas. However, yes, you were in favour to create some kind of modified or transformed Enlightenment. Your attacks of the conventional Enlightenment, was done so in the name of a project that is in its goals and in many of its methods, fundamentally enlightened. Isn't for you the *Übermensch* or Overman – as neo-aristocratic, this-worldly figure of an avant-garde – representing the fulfilment of a different but, profoundly 'enlightened' project'? And for you this is realised by facing and affirming willingly, the most abysmal thought that is the eternal recurrence of everything and *amor fati* or love of one's destiny, passionately beyond endurance and fatalism. While this affirming might include suffering, pain and evil, it allows creating the meaning of the earth anew, and faithing into a future, yet to come. Importantly, for you this fate-loving overman does not mindlessly accept the world fatalistically with all its sorrow. Rather, the true power of the one, who overcomes lies in his or her ability to choose and make decisions, as s/he is able to affirm only that which is worthy of being affirmed (2002).

Hegel: Wait, wait, I think we need to radicalise your philosophy Kant, through understanding an absolute as all-encompassing, self-realizing spirit that includes otherness. Enlightenment reason (*Verstand*) with its insistence on abstract opposition had to be integrated into a more comprehensive, speculative, form of reason (*Vernunft*) of absolute knowledge as *Weltgeist* that could even unify the opposition between unity and difference. This allows us to think dialectically of what Enlightenment reason excluded as other than reason, as reason's own other. With this transformation of the Christian eschatology into Absolute Spirit, the 'cunning of reason' into the history helps to rationally comprehend that all tragedy and suffering, are part of the progression of the Spirit.[21]

---

[21] **Critchley:** Well dear Hegel (and Marx) tragedy is neither progressive as you thought or regressive as others would have it, but retains an 'ambiguity' to be reconsidered. What if we took seriously the form of thinking that we find in tragedy, and the experience of partial agency, limited autonomy, deep traumatic affect, agnostic conflict, gender confusion, political complexity, and moral ambiguity that it presents? Adopting a theatrical standpoint, in the tragedies reason is not a tool that can stabilise the contradictions of experience. Rather, tragedies are giving voice to what is contradictory, constricting, and limiting about human beings and the space between freedom and necessity. The power of tragedy as a political mode lies in its tendency to subvert the penchant for reasonable, neat plots and outcomes! It confronts us with the unknown forces that move human being and doing in the basic activities of life, including love, war, worship and grief. Thus, it confronts us with a chaotic order of dissonant energies where multiple claims on our lives have reason on their side! Tragedy is thinking in action, thinking upon action, for the sake of action, where the action takes place offstage and is often described to us indirectly through the character of a messenger. This type of thinking, is not resignation but rather disorientation, and takes the form of a radical questioning: How do I act? What shall I do? And this in a fractured world, without the capacity for redemption and of 'irreducible violence revealed by tragedy! (2019).

Marx: We need to put this spirit on its feet and realized a revolutionary practice. Yes history follows dialectic meaningful pattern of progress, but it is be found in relation to concrete material, economic conditions of human existence, in particular modes of production and labour.

Darnton: By the way, we need to see the material basis of literature.

Sangmeister & Mulsow: ….including the dissemination (sic!) by erotic. pornographic novels and gossiping short stories, expressing also political critique!

Darnton: …. literature and the technology of its production and distribution – including roles of publishers, book dealers, traveling salesmen, and other intermediaries in cultural communication – that affected the substance and diffusion of ideas, including those of the business of Enlightenment!

Marx: History unfolds towards enlightenment in a rational process towards greater freedom and rationality, but through a conflict of classes over resources! You philosophers also all you of enlightenment until now have only interpreted the world in various ways. The point, however is to change it! We need a collective prâxis, as activity of human emancipation to overcome all forms of alienation, and reification. A from this prâxis new social formations, ideas, theories and consciousness and ultimately a post-capitalist communism as gruel enlightened way of living together in perpetual peace will emerge.

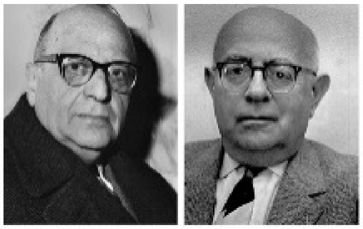
Post-Colonialist: Related to your critique, I still try to understand how it came about that liberty, intellectual freedom, and constitutionalism were in many or most cases actually set back, rather than advanced in 18- and 19 century Europe, and still more in the European colonial empires, despite the tremendous escalation in the justifying rhetoric of enlightenment, liberty, and reason. Disinclined to oppose actual inequalities and hostile to actual universalising proclivities, on the contrary 'enlightened' reforms and rhetoric were misused for crushing opposition, suppressing criticism, and furthering colonial economic exploitation often for consolidating personal control and profit.

Historian Israel: Well this is a known pattern: ideas promoting the interest of society as a whole came to be almost defeated by ideas buttressing the interests of the privileged few (2019)!

Observer: Hello again! Just as a brief comment from my meta-position**.** Again different historical voices and patterns of thinking and relating to the world by emphasizing different perspectives and orientations, as particularly expressed by Nietzsche and Kant who represent voices of that influential intellectual and philosophical movements in Europe during 17, 18, and 19 centuries.

As we have seen all those distinct and critical understandings and interpretations of Enlightenment are themselves enlightening. Revealingly, but also elusive the status and role of objective rationality, subjective relativism, logos and pathos, status of reasons, monist-unity and pluralist orientation, evolution and revolution were put and seen in quite different lights, twilights and/or shadows.

By listening to the next round, we come even closer to our times including what we used to call modernity and postmodernity, entering 20 century. These are voices from Critical Theory, expressed by Adorno, Horkheimer, and Habermas in dispute with poststructuralist/postmodernist, especially Foucault, who is even speaking with Kant directly.



Max Horkheimer and Theodor W. Adorno: Yes my dear Kant and Hegel as well as particular dear, lieber Karl Marx: Enlightenment, understood in the widest sense as the advance of thought, has always aimed at liberating human beings from fear and installing them as masters. Yet, the wholly enlightened earth radiates under the sign of disaster triumphant (1947: 3).

In the process of enlightenment, modern philosophy and (positivist) science, especially in the 20th century, had become over-rationalized and an instrument of technocracy. There is a continuity of the age of myth within Enlightenment and modernity. Modernity fulfils what myth always wanted to. For us, Enlightenment is a kind of totalitarianism. It is mythical fear radicalized! Enlightenment regresses to the mythology it has never been able to escape. Thus: 'Myth is already enlightenment, and enlightenment reverts to mythology' (1947, p. xviii). Accordingly, we need to reflect critically the "*Dialectic of Enlightenment."* With this orientation, we can understand the relapse of reason into mythical irrationality that leads to the necessary distortedness of reason.

Cassirer: As I have experienced painfully it, the NAZIs, had combined the regressive and mystifying powers of myth with technological advances and the methodological precision made possible by the Enlightenment (1946, 282-92)

Horkheimer and Adorno: As propounding a rationalist dogma without capacity for self-criticism, Aufklärung was and is bearing a potential for the massively efficient and dehumanizing myth-making perfected jointly not only by NAZI propaganda but also by what we experienced and observed at the (American) 'culture industry'!

Bredvold: Even worse: we will see the breakdown of civilization as the result of the Kafkaesque systematizing of the modern age inaugurated by the 'Brave New World of Enlightenment' (1961).

Gray: Enlightenment's wake is the close of the Modern Age (1995)!

Horkheimer: And therefore, we need moving from traditional theory towards critical theorizing! And you Nietzsche as a defender of naturalized, elitist, socio-political hierarchy and stance against democratization appear as anti-emancipatory, conservative even reactionary (2011).

Heike Schotten: What about rereading and reinterpreting Nietzsche's critique re-deployed from the queered perspective of the other and the oppressed? Let us openly and radically embrace immoralism in the name of emancipatory rejecting and undoing morality and its array of punitive moralisms (2009, 2018).

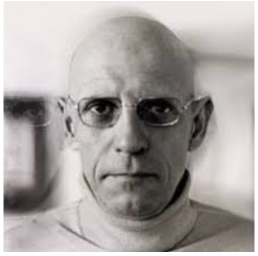
Adorno: Moreover, we need moving away from identificational and teleological approaches towards mimesis and a negative dialectic that allows a systematic critique for example of the cultural industry as one of the ideological distorted forms of capitalist society. As our life in late modernity that is an inhuman society affecting everyday behaviour, a good, honest one is no longer possible. While we live in an untrue whole, No Hegel not as you stated: „*Das Wahre ist das Ganze*" ("The True is the whole"), but „*Das Ganze ist das Unwahre*" (MM 55), ("The whole is the untrue") and „*Es gibt kein richtiges Leben im Falschen*" (MM 43) ("There is no right life in the wrong one")!

Nevertheless, with my friends, like Walter Benjamin, I have had still the vision of redemption as only valid viewpoint with which to engage a deeply troubled world. By bringing the "Messianic light" of criticism on a landscape of consummate negativity, I tried and suggest to you to project negatively an image of utopia (1978 *Minima Moralia*), while you are facing those crisis and re-totalitarising developments again. For me late capitalism totalitarianism is an ineluctable destiny of modernity.

Arendt: Totalitarianism is a system of power that destroys politics. As such it is an attempt at building a monolithic, homogeneous community in which any form of pluralism and division of the social body is eliminated, thus destroying politics as realm of infra, a space of interaction between citizens, very different human beings sharing a common political sphere as equal actors (1951).

Leftist: We need to fight political totalitarianism with its abolition of pluralism and representative democracy, suppression of constitutional rights, concentration of power and leadership and persecution of deviancies. Similar let us critique economic neoliberal totalitarianism that would lead to a reified world, in which all human and social relationships take a commodity form, and in which the market becomes a universal anthropological model and human beings are unable to conceive of their relationships outside of individualism and competition. Such a world would be totalitarian, though even dressed in anti-totalitarian clothes of market and individualism as symbols of freedom against racial and class collectivism.

Koselleck: We need to understand the conceptual history (*Begriffsgeschichte*) notions of Enligthenment and related 'modern' guiding terms and meanings and when and how they were employed. The study of the changing semantics and pragmatics of these concepts in their social and political contexts showed that these were transformed during the transition time between circa 1750 to 1850 that I call 'saddle period'. Moving from civic-war preventing absolutism, to englightenment, to French revolution, away from transhistorical-static to future-oriented anticipatory contents including showing a more dynamic form as politicisation, democratisation, ideologisation. Also contemporary understandings of politics have become dangerously depoliticized by Enlightenment utopianism! As I have shown in my book "critique and crisis – pathogenesis of bourgeois world" the modern that orginated out of the Geist of Enlightenment carries the seeds of its own crisis due to a critical understanding of an enlightened understanding of history.



Foucault: Well my dear friends, "What is Enlightenment?" – *les Lumières* – is also a question that I processed and which I propose to re-open. I took up the formulation of daring to know, and became very interested in the interpretation of Enlightenment as a modification of the preexisting relation that is linking will, authority, and the use of reason. As you all were in your time, pursuing your own philosophies, I was intrigued to think about and to find a place for the individual as supposed autonomous man and woman in my time and what is called post-structuralist and post-modern philosophy that is rejecting Enlightenment metanarratives.

Lyotard: *nodding* intensively, oui! incredulity versus totalising grand narratives, méta-récites! Where, after the metanarratives, can legitimacy reside? My answer: Avec *petits récits*, or more modest and localized narratives and local micro-legitimations, as a progressive politics has to be grounded in the cohabitation of a whole range of diverse and always locally legitimated language games (1984)!

Foucault: Connected to my thinking about critique, governmentality and resistance ("Qu'est-ce que la critique?"1978), in reopening this quest(ion)–that became my last lecture (1984) and you may see it as a testament, I tried to come to terms with the problematic legacy of the so-called age and project of 'Enlightenment'!

Kant: Monsieur Foucault, Qu-est-ce que les Lumière pour vous?

Foucault: Pour moi, cher Monsieur Kant, your interpretation of Enlightenment as the opposite to a state of immaturity or tutelage, specifically as incapacity to use one's own understanding without the guidance of another (heteronomy) are interesting. I find it fascinating how you suggested a connection between an excess of authority, on the one hand, and a lack of courage and resolution, on the other. You showed that the courage to know is at one and the same time the courage to recognize the limits of reason (to be seen as a play of power and truth that is of obedience and argument, acknowledging the authority of the sovereign and a self-determining subject retaining its autonomy) thus critique as art of 'voluntary inservitude.' I see the domains in which the contest between a state of immaturity and one of enlightenment takes place are those of the opposition of critique to governmentality, namely, religion, law, and conscience.

Kant: *et voila! comme je dis!*

Foucault: Turning directly towards Kant: Interestingly, for you Kant, Enlightenment has to be considered both as a process in which men participate collectively – even universally – and as an act of courage to be accomplished personally. Thus, men are at once, submissive elements part of an imposed agency and voluntary actors and of a single process. One of the most bewilderingly unsatisfactory moments in your essay is that famous and fateful distinction between the realm of obedience[22] and the realm of reason, among other dichotomies, like duty and inclination and coercion and freedom as well as transcendence and immanence.

---

[22] Your obedience with this notorious nonaggression pact (tutelage of a king?!) with Frederick the Great, committing yourself to applauding the sovereign's suppression of politically subversive acts in exchange for your own intellectual liberty disappointed me. A subtle, daring, and psychologically penetrating you Kant may have enticed a sovereign hungry for a reputation, not just for overmastering puissance, but also for wisdom into an agreement in which the sovereign obliged himself to permit freedoms that the philosopher well knew might be radical in their ultimate, if not their immediate, effects. Perhaps a generous heart might argue this is why the argument conveys a powerful sense of lulling: In some ways your obedience anticipates not liberal democracy, but totalitarianism. Accordingly, Answers to the Question: 'What Is Enlightenment?' would then be (1) a piece of flattery thrown off by a tame intellectual; (2) a shrewd effort to circumscribe the sovereign's recognized appetite for the suppression of (especially religious) dissent; and (3) a prescient disclosure of the (totalitarian) obscenity of Enlightenment itself. Whatever it was, it did not work. When you published "Religion within the Limits of Reason Alone" nine years later, you were rebuked by the official censor and forced to apologize. This exercise of old-style power in the very heart of the Aufklärung raises once again the initial question: What is Enlightenment?

In retorting to your propositions for intellectual courage, I do not share anymore that inherent spirit of rational optimism for a fulfilling promise of reconciliation or happiness – and naïve faith that all will be good via rational reasoning and universally valid statements – that are inherent in your thought. Even more, I do reject much of those hopeful politics that were proposed by you Kant and your contemporaries and those, who followed and still follow.[23]

Kant: But for being enlightened, we must understand that the private use of reason renders individuals both submissive to external political authority and identifiable in terms of strictly definable social roles. This has ramifications at both the level of the individual (ethics) and that of the collective (politics). To see reason as that what must be free in its public use, but submissive in its private use, is opposite of what is ordinarily called freedom of conscience! The question we are called to ask is how can we take the use of reason the public form that it requires, how can the courage, the audacity to know be exercised in broad daylight, while individuals are obeying as scrupulously as possible? For responding to this, we need a transcendental, formalized system that allows universalization.

Foucault: For me, the criticism inherent in critical work of reason is no longer to be used in the search for formal structures with a universal value. Rather, the task of Enlightenment thinking is to make a historical investigation into those particular events that have led us to constitute ourselves and to recognize ourselves as subjects of what we are thinking, doing and saying… How does the 'Age of Reason' had to construct an image of 'Unreason' – and treating all those 'insane' accordingly – against which to take an opposing stand…

Facilitator: Can you rephrase this and elaborate please?

Foucault: In other words: The ways in which we think and act or the rationalities or games of truth that we play out in diverse institutional fields have a history and should be analysed as a product of particular contingencies and struggles. Accordingly, I see a great potential in a genealogical critique to understand the constitution of sub-jectivity. We do not have to be for or against the Enlightenment and do not need to escape the principles of rationality. Rather, we have to accept that the Enlightenment was a powerful event or set of events that has made us, who we are. What role did power play for being free, how much was there a force to be autonomous, and what delusion of progress were all stabilising each other based on rationality?

---

[23] The idea of a people ruled by just rulers; ethical leaders and those 'modern' heroes, well-educated class scholars and academically trained men of genius, spokes-persons of the Enlightenment, who are inspired by the existential dare advised in the phrase sapere aude and the idea of a transcending knower, all of this appears to me as problematic. My underlying issues and question is how do we experience our own freedom, our ability to reject as freely as we affirm possibilities for our lives, without falling prey to nihilism? Without engaging in a form of criticism that once again emphasizes limits rather than the transgression of limits and the production of possibilities? Concerning the promise of Aufklärung, in relation to expectation of autonomy, and claim for authenticity see Rosa (2010).

The problem is not rationality as such, but the form it took and can take. Such critical reconstruction is a vital resource for questioning societal, political, economic or managerial regimes as 'common-non-sense' and ideologies. We need debunking them as oppressive and limiting systems of thought that inhibit our capacity to imagine other possible ways of organizing and living.

Kant: What does your historical and genealogical interpretation imply, in particular in relation to status of the Reason of Enlightenment and the autonomous subject?

Foucault: Historio-genalogically, there is not an essential kernel of primary universal rationality and an unified rational subject that you Kant and your followers presumed to be found during the process of enlightenment. There exists multiple and historically specific forms of rationalities, due to which reason can never discover its essence or founding act. Rather, what is reasonable can only reveal different modifications in which rationalities engender one another, oppose and pursue one another as well as the elements of rational disintegration within the subject itself and within reason. Accordingly, I re-interpret sapere aude as practice of a radical, critical thinking and as a permanent reactivation of an attitude and an ethos as a critique of our and your historical era and practice of fearless speech (2001).

Facilitator: What does this mean for our lives? How can we dare to be wise today?

Foucault: For me, daring to be wise is realizing a life – in sensu of the aesthetics of existence – in which the critique of what we are can be found and unfold, while promoting possible changes and thus the practices of freedom, including restraints imposed by institutions. Such an enlightening approach applies pluralized and decentered reason to experience. This kind of criticism and lived aesthetics is thus an experiment with the possibility of going beyond forced limits, of centred modern individuality in order to reach intensifying limit-experiences. Then adopting an 'ethos of enlightenment' enacts experimentally a courageous practice of liberty (1984: 1388–1393) as perpetual self-elaboration and self-problematization (1984a: 1431, 1984b). And such orientation is moving towards perpetual becoming by creating our-Selves as a work of art (1983: 1211) also as one involved organizing and managing (Bardon & Josserand, 2011). Thus, rather than universal structures of reason it is all about autonomous self-government and aesthetic self-creation. Being critical against the 'modernist' colonialization of perception by our logical faculties and cognitivist assumptions of high modernity, such aesthetic program is about tuning in and turning toward tactile and passionate alternatives.

Facilitator: I understand your emphasis of ethos-oriented, aesthetic and critical orientation! But how is this approach different compared to the progressive continuity of traditional enlightenment?

Foucault: Turning the life and body of an individual into a transgressive site of a living artwork, does not merely continue your tradition of philosophical Enlightenment (*Aufklärung*). Rather, such undertaking transform the same into a new program of sublation (*Aufhebung*), which is a different one compared to what you Hegel, or you Adorno and Horkheimer thought of. Here '*Aufhebung'* is taking and lifting up ('sub-late') that is exceeding the limits and decoupling of the autonomous spheres of aesthetics, ethics and politics as well as those between the supposed 'high', (rational, universal) and the devalued 'low' (passionate, bodily, historically engaged). Taking Enlightenment as the 'on-going' age of critique (1997: 308) calls us to ask what this means in the very historically constructed and relative present that is the neo-liberalised global world in the 21 century!

Facilitator: Speaking about present, can you share your pondering about why unenlightened politician and populists and their programs are 'successful' today?

Foucault: Well, in a way, this does not surprise me! I fear that it is a kind of 'normalization' of foolishness that will dominate more and more. I am concerned about the far-reaching implications if this all becomes a generalized 'normal-ness' and when old or new authorities are imposing order to achieve obedience and conformity. Therefore, for me, the question is in particular how 'Discipline and Punish' are used that is which and how ordering disciplinary technologies, and 'micro-technique of power' are employed for which purposes.

Moreover: How are power and knowledge as well as its nexus exploited for what kind of supposed 'post-factual' or 'post-Truth' politics? Furthermore, what forms of '*governmentality'* emerge from all this, defined as all those organized practices (mentalities, rationalities, and techniques) through which subjects are governed? In particular, how are these visions policed by social pressure, while attacking and excluding other imaginations and undermining subversions?

Malette: To be added with „Ecogovernmentality" for considering and as a response to our ecological crisis!

Kant: Considering all this, will we as mankind ever enter a genuine enlightenment of living maturely, and autonomously in freedom ultimately?

Foucault: My dear Immanuel: Considering your hope for humankind's final coming of enlightened emancipated age, I do not know whether we will ever reach such mature post-dogmatic adulthood and freedom. From my perspective, we can never become totally free, because freedom is not a fixed state of being. Rather, *becoming* free is alive in possibilities to create ourselves and transgress the limits imposed on us, not in the sense of overcoming these limits, but as illuminating and critically testing them. What is important is that 'the process of transformation from immaturity to maturity – on your terms Kant - can be enhanced, valued, and intensified insofar as it is a process of realisation (Pryor, 2002: 320-1). This is what being 'determined' by the Enlightenment means and engages us with a 'trans-evaluation'. So you see, I am not an anti-Enlightenment thinker! What I try to do – at least in my late work – is re-visting and reworking some of the central categories of Enlightenment and it values, such as the interrelated notions of the caring self,[24] autonomy and emancipation.

Facilitator: What does sapere aude then call for today? Is your approach not an elitist and aesthetising one that for many people appears us unreachable or even 'otherworldly'?

Foucault: Sapere aude in our times calls for and enacts an entanglement of aesthetics and ethics of self-empowerment and -unfoldment! Please hear me right, I am not for a decadent or otherwise understood aestheticism, nor any kind of frivolous aestheticization or light-headed 'devil-may-care' form of dandyism. Because of their critical function, aesthetically refined and artful practices of the caring self are not confined to aesthetics. Rather, they are also essentially part of one's personal and interpersonal realizations of ethics, politics and freedom. Thus, these practices are searching and creating alternatives to modern self-subjugation.

It is about re-defining identity as a site for cultural resistance and individual autonomy that might pave the way for alter-native styles of living and identification. And critique will be the art of voluntary inservitude, of reflective indocility and a care of the self!

Derrida: All critique and deconstruction for an 'Enlightenment to come: Le monde des lumières a venir! (2003).

Habermas: There are many misunderstandings here! What we need is: '*sapere aude in communitas'* via what I call Communicative Reason – beyond your Kant monological approach – and that implies following the regulative idea(l)s of ideal speech situation and ever better rational argumentation. For me valid knowledge can only be reached in 'ideal speech situations' where the only acceptable power is that of the 'better argument.' I thus invite you to respect the rules of the 'discourse ethic' to reach a consensus, which would constitute the condition of our emancipation (Habermas, 1994). In the best Kantian sense, the normative criteria of any 'validity claim' is universal and it is the only acceptable way to emancipation as enlightenment in 21 century! Since validity claims require that interlocutors justify their claims to reach a consensus, they will subscribe to a universal morality that they agree to and can live up to it.

Your totalizing critique of reason, my dear Foucault, deprives your own work of the normative grounding and still requires civilizational approach and perspective, everything else would be a performative contradiction! And this modernist heritage is part of the very Enlightenment goals of human emancipation and the expansion of reason, non-violence, and recognition of and in relation to the ‘other!

---

[24] Foucault's French translation of the old concept of care 'to 'care of the self' or 'care of oneself' Le souci de soi i.e. 'attending to oneself' or 'being concerned about oneself' (Foucault, 2005, p. 2) is not an egoisticprocess; but it is an action that includes relationships to others, where the individuals are involved with each other through shifting constellations.

Modernity, initiated by Enlightenment, is a worthy project – albeit unfinished. Modernity is unfinished, because there is a gap between the specialized knowledge i.e. scientific, moral and aesthetical knowledge and everyday life. It is worthy because of the gains it has made, especially in the expansion of individual freedom and a post-national orientation, urgently needed in our times of neo-nationalistic resurgence.

To complete the project of modernity requires a discursive selection of scientific, moral and aesthetical values that the modern enlightened age has to offer that is created its normativity out of itself. And this discourse-based process have to be organised in such a way that there are more possibilities for valid claims, while not compromising the lifeworld by the encroachment of systems of power and money.

Foucault: From the beginning with the reformers of the Enlightenment, modernists have succeeded in influencing the mind by turning the individual into an object of knowledge. Hence, the glorification of knowledge lies not in its capacity to understand the objective world as commonly celebrated by Enlightenment thinkers. Rather, modernist power lies in its success in microscopically analysing the internal and the external conditions of individuals to allow better institutional coercion thus, processing a normalization of human behaviour and enforcing the power structure of modern society.

All communication is integrally embedded in power in an existing social system, serving interests of domination and manipulation as much as enlightenment and understanding. Language and knowledge are subject to historically contingent and specific constraints and biases in contemporary society. These are functionalized and rationalized, their meanings and uses are socially constructed to serve hegemonic interests, including legitimation and control and so never universal and transcendent of social conditions.

Dear Habermas! Your vision of enlightened communication through which minds can meet, and a shared understanding can be established, truth can be revealed, and that unforced consensus can be reached, is merely a utopian ideal, like the regulative ideas by Kant before. Even more, and you won’t like me saying this, but your emphasis on discursive-mediated political will-formation through the process of deliberative and procedural democracy, as your discourse theory conceived are very problematic. These discursive processes that cultivate rational and moral subjects through reflection, argumentation, public reasoning, and reaching consensus are and remain illusionary and may be misleading.

Habermas: No, I am not convinced and do not agree at all, on the contrary: Your approach remains for me a detractors of reason as you cannot account for an alleged validity of itself you claim and collapsing the ineluctable Kantian distinction between genesis and validity, between questions concerning the factual origin of claims and its possible justification on grounds that cannot be reduced to its de facto origin.

Like Nietzsche, you are blurring the principal distinction between the three equiprimordial spheres of claim and adjudication: the cognitive sphere in which claims concerning factual correctness are raised and adjudicated, the moral-legal sphere in which claims concerning normative correctness are raised and adjudicated, and the aesthetic-critical sphere in which claims regarding artistic authenticity are raised and adjudicated. Therefore, I have to dismiss your genealogical historiographies as relativistic, and crypto-normative illusory science. You are not giving an account of the normative foundations' for your thinking. To avoid relativism our thinking must be rationally and universally grounded.

Again, we need a minimalist theory of rationality that attempts to replace the unacceptable substantialist notion of reason as universal subject with a conception of rationality based on reason as the necessary standard of interaction between subjects that rely on each other for the recognition and adjudication of their claims. What we need is a communicative rationality and to keep the emancipatory potential of reason alive. This alone allows developing a deliberative democracy, whereby only the weight of the better argument prevails.

Foucault: Monsieur Habermas, you are functioning as a standard-bearer of the legacy of Enlightenment rationalism, and a corresponding normative stance. But the distancing from foundationalism and metaphysics does not leave me normless or without any value-orientation. Norms cannot be given a universal grounding independent of those people and their context. Contextually situated, my norms are expressed in a desire to challenge 'every abuse of power, whoever the author, whoever the victims' (Miller, 1993: 316).

No, mon cher Jürgen Habermas, it is not the force of better reasoned argument that encourages consensus by informed and intellectually competent citizenry. Rather, it is through control of minds that produces compliance. As we are institutionally coerced into complying with the norm of docile body, we must re-empower and re-embody ourselves!

James Schmidt: There was and is a lot of problematic misunderstanding concerning the very question ‘What is Enlightenment?’ and need for rethinking today as well as with regard to the debate between Habermas, and Foucault (2011, 2018ab).

Matytsin, et al.: And we should not underestimate the religious and mystical sources of the rationality of Enligthenments (2018).

John Dryzek: Let me add a word on embodied dimensions. Part of this embodiment is extending and re-interpreting communicative rationality to be open to unconstrained dialogue with the non-human voices located in the natural world having its own agency (Dryzek, 1998: 588). This is relevant also as the ‘ideal speech situation’ seems somewhat detached from the realities of the empirical social world and lived experiences in all their corporeality.

> **Observer:** Before we learn more about the reality of this corporeality related to wisdom and enter a preliminary final part, once more, a few words of transition from me the observing agent. After all those radically critical reflections, ideas and approaches situated in creative tensions between modern and post-modernist orientations, we now turn to embodied wisdom, the tasteful original, presence and future of sapere and sapiential. With this we re-enter the territory of embodiment, and will hear about sensual qualities and

moves towards a more integral understanding of wisdom and Enlightenment. Thus, enlightenment interpreted as a period, practice, and project may has been winded up and further unfolds as various accounts required it (Schmidt, 2011) and as our voices here confirm. And as we will see, with its Leitmotiv and call for daring to know and becoming wise sapere aude well again and remain in need for a further interpretations, different realisations and 'creactive' enactments as the open(ing) questions and quest in the end invite….

Merleau-Ponty: Yes, daring to be-come wise in the 21 century calls for being re-embodied.

We need to move away from the cerebrocentric, information-processing, and representational models of mind, cognition, knowledge and wisdom towards the corporeal, enactive, and world-involving understandings and relationships.

Varela: even more a "*dis*enchantment of the abstract," i.e., for a move away from "the rarefied atmosphere of the general and the formal, the logical and the well-defined, the *represented* and the foreseen" and a "*re*-enchantment of the concrete," i.e., for a "radical paradigm shift" based on a stronger recognition that "the proper units of knowledge are primarily *concrete*, embodied, incorporated, lived" (1999, 6-7).

It is about embodied meaning as experiential, lived-through in and through practices that bring forth and allow further emergences of incarnated and cultured existence as well as living 'civilisation.' These bodily-mediated practices are not (only) those of sub-jugation, not merely processes of sub-jectification through which the individual submits to the imposition of social forms and passively mediates this imposition. Rather, incorporeal meanings are really more intricate, and open for transformative creativity than are the meanings imposed by social formation.

Spinoza: Knowing what the body can do is the route to better knowing, and, ultimately, the kind of grounded wisdom or 'blessedness' that I see as coming from recognising the world's immanence to our own being.

Jonathan Israel: you dear Baruch Spinoza and the so-called Spinozism were the intellectual backbone of the European Radical Enlightenment (2001) and foundational for the origins of modern democracy (2009).

Shaw: Yes: Men are wise in proportion, not to their experience, but to their capacity for experience (1903: 239).

Bähr: How the body was constructed and killed in and by enlightenment showed its limits.

Polylinguist: And with this, we need a taste-ful understanding of wisdom as the very ‘s*apere’* means in Latin and before all to taste! In French, *tâter*, that is to palpate, to explore by touching, is kin to the English taste, to explore by the mouth, ‘*aude sapere’*, thus could also be translated as ‘dare to taste’, and in Spanish ‘*con sabor’* also means with gusto. [25]

Serres and Latour: Yes, human ancestors associated wisdom with taste as the Latin sapien(t)s connotes knowing and wise with ‘tasting.’ Taste, i.e. *sapor*, is itself knowledge (*sapere*), and thus wisdom (*sapientia*), an association that is also present in the present participle of sapere ‘to taste, to savor’ and ‘to be wise’ (which also gave us sage and savant). While sapient suggests subtly sensing flavour and aromas, having taste as sagacity, sane just merely stresses mental soundness, rationality, and levelheadedness and judicious emphasis a capacity for reaching wise decisions or just conclusions. Accordingly, homo-sapiens means both ‘men of wisdom’ and ‘men of taste.’ When we say homo sapiens, we should keep in mind that the origin of the notion of wisdom, or of discourse – man as speaking man – lies in the capacity to taste with the mouth, and with the sense of smell (1995).

Hutcheson and Hume: Oui, Si, Yes, value judgments are expressions of taste, rather than reasoned analysis alone. And the faculty of taste can be used to determine an object’s aesthetic value. Thus taste is a productive faculty, and gilding or staining all natural objects with the colours, borrowed from internal sentiment, raises, in a manner, a new creation of beauty and deformity, virtue and vice. For use, taste is immediate and spontaneous, yet the application of ‘good sense’ and sound understanding of ‘reason’ improves it. Accordingly, for cultivating this valuable taste we need to expose ourselves to variety, learn about artistic media and practice imaginative associations and pleasure of ideas. Tasteful aesthetic appreciation involves disinterested delight that does not regard the aesthetic phenomena as a resource or instrumentalist tool for serving our interests and purposes.

Kant: Indeed, cultivating taste reasonably is vital and aesthetic judgments of taste must not only be disinterested, but also be universal, exhibit purposiveness without purpose, and be necessary. It is the objective, disinterested, pure aesthetic pleasure in the presentation (Vorstellung) that allows a universal agreement, validity and judgement.

Deleuze, Lyotard, and Rancière: Considering your third ‘Critique of Judgment’: What about rethinking the formless Sublime as incomprehensible event and a kind of aesthetic break and reconfiguration that challenges all tastes, imaginations and sense-making while providing openings for new political formations and initiatives?

---

[25] Dare to be-come wise was and is about a cultivation of the Wo-Man of taste, who share those in a proto-political community. Displaying taste as an exercise of judgment even and especially in public affairs would enable citizens to regain, having pursued a sense of place in the world.

Romantic Poets: Yes, yes sublimity, the elevation of the sublime that is the very visionary gleam of being lightened![26]

Shapiro: In particular, the experience of a 'Political Sublime', including contemporary threats of annihilation and violence, may lead to an ethico- political sensibility that recognizes the fragilities of our grasp and enjoins engagement with a pluralist world in which the in-common of different communities must be continually negotiated (2018: 4) and thus allowing to reveal, redistribute, and create conditions of possibility for alternative communities of sense.

Kant: Well these are all post-Kantian ideas that go beyond my understanding of the sublime as overwhelming overawing the imagination a presentation of an indeterminate concept of reason recognized by the same. For me your political interpretations are not compatible with my commitment to a universalising community of taste: sensus communis, as we seek in reflective judgment we seek unknown universals. Only transcending from individual whims and idiosyncrasy, there can be a common sense and correspondingly, taste reflects the transcendental principle of general acceptability, and only transcending from individual whims and idiosyncrasy, there can be a '*sensus communis*.' And we need to focus also on the beautiful, and the good, connected with the form of the object!

By the way, for cultivating taste in a social context, I have developed rules for a tasteful feast at our 'Tischgesellschaft,' which is a kind table community for gathering at a dinner party:

a) To choose topics for conversation that interest everyone and always provide someone with the opportunity to add something appropriate,

b) not to allow deadly silences to set in, but only momentary pauses in the conversation,

c) not to change the topic unnecessarily or jump from one subject to another . . . topic that is entertaining must almost be exhausted before proceeding to another one . . .

d) not to let dogmatism arise or persist, either in oneself or in one's companions in the group (e) in a serious conflict that nevertheless cannot be avoided, carefully to maintain discipline over oneself and one's emotions so that mutual respect and benevolence always shine forth (Kant, 1798/2007a, p. 381, 7: 281)

These rules are providing the guidelines for sociable exchange and, more generally, ethical and productive conversation! Such sociality cultivates not only taste, but in various ways, the very vitality of the body and the mind related to pragmatics (Ercolini, 2012). Thus the conversations should be of taste, and enjoyable, while leaving the guests feeling something had been accomplished on the level of culture. At the same time, the conversations are regulated by certain rhythms, specific movements, and itineraries (Kant, 2007; Ercolini, 2012).

---

[26] Different from pleasure in the beautiful, the shock of the sublime forces us out of stable states. The sublime is not something we bask in, but something we pass through or undergo. Furthermore, the sublime isn't simple like the beautiful, with its straightforward connection to the pleasurable. The sublime combines passions such as terror and delight (Burke: what I call delightful horror) or pain and relief. As such, though it involves negative effects, these can serve positive outcomes coming as a result of the initial shock.
Charles Taylor: We need romantic expressionism and overcoming excarnation even more as the naturalism of atomising, disengaged and instrumental reason and a disenchanted immanent frame we are living in today.

Friedrich the Great: We need to dine and drink together to bring Enlightenment alive, like in my philosophical "*Tafelrunde*" at my castle Sanssouci and '*Vereinigungen'* in my kingdom.

Ursula Pia Jauch: … I need to throw some light on shadows of that light. In your intimate male circle you staged yourself imitating as a philosopher in Machiavellian ways for using this for your authoritarian paternalistic rule and propaganda. Simultaneously, you did not believe that the majority of your people would be able to be 'enlightenable' at all.

van Dulmen: There would be no Enlightenment in Germany without the emergence and growth of the many different learned societies, clubs and associations, including masonic lodges, and secret societies, winning the support of princes and aristocrats, that created a self-confident bourgeois elite and early middle class culture (1992).

Coffee House owner: This sound rather like a private gathering. What we need are also public places, like coffeehouse where people can congregate, to read, write, to learn and to debate with each other, including urban artisans and businessmen to discuss latest reform ideas! (2004).

Salonnière: What we need is both public and private institution of intellectual sociability. We, as socially conscious and learned women, regularly organised and governed salons in which we were hosting and regulating discussions of literary works, artistic creations, and new political ideas. Although, our need to be recognised us into Enlightenment cultural practice, and our expressions of aesthetic *bon goût* and political ideas were more and more ousted and silenced by the male 'philosophes', for example the misogynistic Jean Jacques Rousseau. And often we were not afforded the same opportunity to publish, and our feminist claims and women civil rights ignored: so much about the supposed ideal of free thinking and openly questioning the world.

Connoisseur: What these salons mediated were also those gustatory moments that shaped individual and communal identities and their style et esprit, sensually and metaphorically! The enlightening aesthetic taste, the nuanced ethos of *gustus* is to be developed through discretionary cultivation of worlds of food and drinks as much of those of words. Just like the tongue and the palate are able to appreciate the quality of dishes tasted, we need to cultivate a faculty that entail judging the value of literary or artistic works and practices.

Used as a metaphor, that is an expression for a set of preferences and dispositions that admit shared social standards and public criticism taste functions for an aesthetic discernment and appreciation or dis-appreciation. The taste of the body as well as the one of the mind is perceived through an immediate sensation of pleasure or repulsion. Having cultivated and enjoying delicate, refined, exquisite tastes, the '*esprits bien faits'* (refined/proper minds especially among the French as a refined form of civility expressed in superiority of their taste) revolt the bad taste as one of excesses or exaggerated artifice; breaking aesthetic rules and declining to vulgar. Instead of awe bad taste is just awful, like kitsch, quite unrefined taste of mawkish sentimentality and faked sensation.

Gadamer: Yes in kitsch as in all bad art e we see only what we already know, not wishing to see anything else. We enjoy the encounter insofar as it simply provides a feeble confirmation of the familiar, instead of changing us. For something can only be called art when it requires that we construe the work by learning to understand the language of form and content so that communication really occurs.” (1986, 52). What is needed is *Bildung* as connected to tact, judgement and taste for acquiring and intensifying sensitivity, subtlety and selectivity as well as a capacity for discrimination. The personal and civic arts of wisdom, when practiced well, can be beautiful, not only in terms of thinking beautifully, but also enacting a beautiful ethical life (1982, 1986).

Perullo: The Wisdom of Taste and the Taste of Wisdom are connected! Wisdom thus does not correspond to a strict rule, but rather to a suggestion: trying to understand as many different experiences as possible in order to joyfully participate in the variety of ecological gustatory occurrences (2016, p. 116). Practical wisdom and gustatory wisdom in particular allow moving skillfully in accordance with the rhythm of experience (2016, 118). Wise taste capacity implements perceptual sensitivity toward little variations and nuances: minimal differences in qualitative characteristics of the objects enjoyed, but above all, minimal differences in the contexts of experience and the connections in which the qualities of the objects emerge….. Wise taste capacity is not acquiescent to extant cultural codes, but expresses critical potential. It promotes the ability to make independent choices and resist imposed models….. Wise taste capacity allows for exploring the connection be- tween consumption and production in the food chain. It therefore allows a critical look at production issues, the environment, nature, and the economy (2016, 124).

von Hoffmann: As a move from gluttony to enlightenment, we can observe a spiritualisation of culinary, medical, religious, and philosophical tastes that is the invention of taste as the seat of a system of representations defined as a new sense modality that was no longer perceived as being exclusively material.”(2017: 136).

Connoisseur: Complementing taste, all senses contribute to an aesthetic sensible judgement. As a ‘*judicium sensitivium’* it processes via integrated operations case by case in a situation-specific way of assessing, appraising and evaluating thus appreciating particular phenomena. The wisdom of taste can also be understood as the constant exercise in gustatory empathy in situations of diversity and contention

Robin Holt and Frank den Hond: What configures enlightenment is the experience of knowledge being created and savoured, especially when daring to push at the edges of convention, to enquire along the limits of common sense. To taste and to dare are far from metaphysical experiences, they are rooted in one’s empirical awareness; enlightened knowledge remains with life and the things of life (2013: 1587).

Serres: Importantly, it is through taste we experience ourselves sensually thus ‘sense-makingly’ as matter, bodies among other bodies, unavoidably ‘complicit with anonymous materials’ in a ‘continuity of material transformations of decomposition and regeneration’, whose immanence, as a certain Adam and Eve experienced, radically denies any transcendent God or Law, facilitating the expulsion from an Edenic world with relatively known consequences. Rather than God throwing out and banishing hu(wo)man from the Garden Paradise, it was the(ir) very act of tasting the forbidden fruit (of knowing) that immediately engendered the collapse of the Garden itself.

This act was and has ever since pro-jected human-kind into the materiality of a world devoid of the hopes and fears of a transcendent beyond. This is our sapid knowledge: “We were too quick to forget that *homo sapiens* refers to those, who react to sapidity, appreciate it and seek it out, those for whom the sense of taste matters – savouring animals – before referring to judgement, intelligence or wisdom, before referring to talking man … Sensation, it used to be said, inaugurates intelligence. Here, more locally, taste institutes sapience (2008: 154).

In doing so we make of our own bodies, our sensibilities, the principle which marks the passage from local to global. It is sensibility which renders our bodies as able to mix, to create knots of relations, and thus to ‘multiply between-spaces’ (2008: 302) in topological transformations. Because we can taste, we can discern and build a practical body of knowledge, a wisdom or ‘sapience’ that materially links vines and grapes with the soil and climate of particular regions. The body ‘smells a rose and a thousand surrounding odours at the same time as it touches wool, sees a complex landscape and quivers beneath waves of sound’ (2008: 306). The senses are then best characterised as ‘exchangers’. They agitate mixtures, make new knots and proliferate space through prolonging and extending relations. A taste becomes a spectacle; a touch gives rise to a song. Sensation becomes the very thread that weaves things together.

Merleau-Ponty: Thus, it is sensation that inaugurates intelligence, and it is taste that constitutes a form of sapience as wisdom! Let us process *Körper* (physical body we have as corps) and *Leib* (we are ‘becomingly’), unearthing the flesh-and-blood texture of lived experience of becoming wise!

Munro: Exercises, as practiced in slow food movement, can help caring for the self (2014).

Panagia: and educating the senses, because there is a political life of sensation (2009).

Küpers: … as does knowing about the “Sense-Makings of the Senses,” applied to organising and organisation (2013a).

Munro: Yes indeed and also cultivating to enjoy the pleasures of ‘conviviality’ by transforming experiences of taste and intensifying the appreciation of the pleasure of eating together mindfully. This entails exercises to test and enhance one’s sensory experiences including: (i) the testing of five taste sensations (sweet, salty, sour, bitter and 旨味 umami in fermented and aged foods, described as pungent "meatiness", "relish" or "savoriness"; (ii) the testing of one’s experience of different aromas in terms of their intensity and duration; (iii) the testing of one’s experience of trigeminal sensations and texture; (iv) the testing of one’s perception of the sound of foodstuffs (e.g. crunchy); and (v) the testing of one’s visual sensations (e.g. smooth and rough).

All of these practise and politics of taste can contribute to micro-emancipations, resistance and creating agents capable of challenging the status quo by running counter to the prevalent hegemonic forms of neoliberal subjectivity (2014).

Green: and not only eating, but also speaking with your own cultivated mouth with maturity. Already the German usages of '*Mündigkeit'* im-maturity refers to the bodily organ of the 'Mund' (mouth) - indicating that the underlying meaning that those, who are '*Unmündige'* (the immature ones) are being unable to speak on their own behalf (1996: 292).

Röttgers: Therefore, we need a 'critique of the culinary reason' (2015). To taste and to dare are far from metaphysical experiences, but they are rooted in one's empirical awareness; as enlightened knowledge and orientation remains with life and the things of life. Daring to know' and becoming oriented by wisdom is the experience of respecting and upending the world into which we are thrown and situated, also culinary. This could be done through enquiry that occupies the space between ordinary, everyday understandings and distant, generalized assertions.

Küpers: Yes, wisdom integrates the particular and the general (2013) and leave the polarising either/or orientation behind, overcoming a parochial identity towards an open integral pluralism. Consequently, it would be wise to leave the metaphorical dichotomy between light and darkness and thus Enlightenment (*Aufklärung/Erleuchtung*) and Endarkenment (*Gegen-Aufklärung/ Verfinsterung*) behind, and not entering into the political game of playing one out one against the other. The enlightenment, *lumieres'* self-conception casted in a denouncing way the supposed *anti-philosophes* regularly in philosophe discourse as obscurantists and deceptive shadow-creatures, while seeing themselves as representing the true and eternal light.[27]

As mentioned before, in the twilight of our complexified times and as many have shown, the binary categories and framework of interpretations and a Manichean struggle between Enlightenment and Counter-Enlightenment are insufficient and its simplistic dichtomistic modes, appear as flat and overly schematic.

Schmidt: Knowing this is itself enlightening, a new level of an Enlightenment (2018b)!

Küpers: Connected to the patterns of the old struggles between the forces of good and evil, the long-lasting popularity of these binarising can be found on their usefulness for polemical purposes. To this their role as pivots of historical narrative is ultimately subservient and might continue to function in the same way today as they did when emerging in former centuries.

Incarnating the wisdom of sapere aude today, daring to become wise needs to be an embodied integral practice. As such it would process positions and oppositions, structuring and de- and reconstructing, moving between aspirations for modernist deliberations and consensus (e.g. Kant/Habermas) and post-modernist dissensus and conflict (e.g. Nietzsche/Foucault) also in relation to a revived practical wisdom for a civil society and applied ethics that is enabling a sustainable development.

---

[27] **Jung:** To emphasise the contrast between the eternal light and the worldly light sources championed by the philosophes, the anti-philosophes exploited the latter's blinding and potentially destructive metaphorical implications to their rhetorical advantage (2016: 219), such as when the Sabatier de Castres warned that the supposed 'lumieres' had in fact proven themselves to be burning torches, ready-made to carry fire everywhere ("des torches ardentes, pretes a porter par-tout l'incendie") (Sabatier de Castres 1779: cf. Deprun 1973: 717).

Flyvbjerg: Practically, this requires wisdom-related, de-biasing planning and *decision making* in *megaprojects,* and *city management* [Ed. Note – italicized text here are links] as well as conceptually a phronetic social science (2015a, 2015b).

Xiang: What is needed is also an 'eco-phrónêsis' as ecological practical wisdom for and from ecological practice - what I call 'eco-practicology', including planning, design, construction and management (2019, 2019a). This wise practice is integrating (moral) knowledge and (virtuous) action and by employing the master skill of moral improvisation the *ecophronimoi* are capable of being responsible in a double sense. That is in any particular instance of ecological practice they are showing "honoring commitments and upholding principles on the one hand and attending specific circumstantial particulars, on the other" (2016: 58), thus enacting ethical beliefs and mindful actions.

Integral Voice: Yes, we need an *Integral Enlightenment* that embraces premodern, modern and postmodern orientation towards a 'postpostmodern' integrative understanding and practice. It embraces the wisdom of the great meditative traditions, but also reaches forward to unleash the profound spiritual potential inherent in our recently evolved capacities for self-awareness, introspection, self-authorship and relational intimacy.[28]

Meta-Modern Voice: (alias Freinacht, 2018, 2019): Yes and even more! Enlightenment for us is the realisation of a 'postpostmodern' integrally informed form of metamodern politics. This is an interactive view of politics that includes the interrelated elements of the Politics of Democratization, Theory, Empiricism, Emancipation, Existence and *Gemeinschaft*[29], enacted by a metamodern aristocracy as avant-garde, reintroduces non-arbitrary and well-founded hierarchies of complexity! A metamodern enlightenment is redefining what appropriate progress and development entails, based on the postmodern critique. But it is doing so without throwing out the hope that we can develop things for the better. Going beyond an anti-thesis stance and deconstructions, the task of reconstructing our symbolic universe and reconnecting it to other aspects of reality. Yes, the great objective of our Metamodernism, is to erect a new grand narrative by combining all known knowledge and wisdom, well aware that it is a never ending endeavour and that the only achievable synthesis (of apparent opposites) is a proto-synthesis of a 'both-and' thinking, forever subjected to critique and never without flaws.

---

[28] https://integrallife.com/integral-enlightenment/

[29] Democratisation Politics, aims to create ongoing processes for developing and updating the system of governance and the quality of institutions. *Gemeinschafts*-Politics (politics of relationships and community) aims to improve the quality of human relationships across all aspects of society. Existential Politics, aims to support all people on their life's journey and spur inner growth mental health and strong moral integrity Emancipation Politics, aims to create ongoing processes protecting citizen from all sorts of oppression, not least from the other new forms of politics. Empirical Politics, aims to evaluate all policies and institutional practices and make sure they are based on the best available evidence. Politics of Theory (or narrative) aims to create ongoing processes for developing and updating the narratives society relies upon, who it "brainwashes itself" (2019, NI, 174-175).

Metamodernism offers to keep the postmodern irony, keep the distance, but creating a new sincerity and self-consciously naive belief on top of it.

Critical Voice: But what gives you critical metamodernist theorists ('the enlighteners') the epistemic authority to tell ordinary people ('the to-be-enlightened') that they are alienated and how they are to be emancipated etc.? Moreover, what if the latter not only ignore the concerns expressed by the former but also enjoy the seemingly disempowering elements commonly associated with alienation and not being emancipated, like in capitalist consumerism and mass entertainment, fundamentalism and tribalism, esotericism and mysticism, hedonism and escapism, populism and authoritarianism. Who are we, as critical theorists, to affirm that those relishing these (or other) types of 'alienation' are victims of social domination?

And your interpretation of wisdom is highly problematic.[30]

Facilitator: What a neo-progressive, re-evolutionary agenda for a game-change, is this metamodernist one, but also those concerns raised are critical ones to be considered and further discussed indeed. What is the future of enlightenment and in particular of homo-sapiens also in relation to other, more-than-human beings with regard to the mentioned sustainable and meta-modern developments?

Future Researcher: With regard to the future of enlightenment it remains ambiguous, defying prediction. The terra incognita of the future is uncharted land, it is beyond what any scientific projection or social prophesy can tell. All what we know is that any pursuit of pure states of being turns totalitarian and incompatible with diversity and plural dispositions of human nature. These might be idealised pasts or utopian futures, supposed true religions, superior races or territorial chauvinism, unsustainable productions, unbridled consumerism. We need to be aware of dangerous forces stirring up at present, including social polarization, economic failures, local, regional and geopolitical conflicts, environmental degradation, barbarised social chaos and disintegration on all levels and all over.

---

[30] Let me respond to your section stating that "Wisdom Is Overrated" https://metamoderna.org/wisdom-is-overrated/ Your discussion criticises rightly certain interpretations of "hyped wisdom," I have trouble with your "Wisdom Troubles" as a "relatively overrated notion of wisdom and spiritual enlightenment". Wisdom does necessary entail believing in "a variable that is always good, and the more of it, the better" (connotation of goodness and normative, perfectionising progress orientations are historical relative, constructs, to be deconstructed and misunderstanding wisdom in the sense of a resentful and self-righteous moralism to be attacked by all means! For me wisdom is not "entirely beneficial and unproblematic" While sharing your scepticism there are attempt to "operationalize" the concept; to make it workable and it is possible to show what and how wisdom is a practice (not only for solving wicked problems). That wisdom is appropriated by preacher of ascending "higher consciousness" does not exclude its relevance of being an embodied down-to earth practice! Wisdom is not (only) about "inner dimensions of people and society and the possibility of an active and deliberate development of these". There are integral and interrelational understandings of practical wisdom that criticises and leaves those reductive ideas behind. Yes we need to consider different developmental capabilities and context, influencing wisdom as a processual culture-dependent practice evolve! There is empirical research on showing in which context and "mechanisms" wisdom has what kind of complex effects that are not always "good", sometimes even tragic! Yes, you are right, there is a danger that the concept of wisdom becomes a projection folio for wishful images and desires, and like you I am in favour of specific, operationable "stricter" definition, related to an uplifting "great depth" and we could discuss the status of complexity of the same. Although the quest and question and methodological challenges of measurability required an elaborated investigation and practice in empirical research. Wisdom is (not only a combination but) a proto-integral development practice of bodily, mental social structural systemic health, with high processual complexity and uplifting great depth. Considering a more comprehensive understanding and the actualisable potential of a practice of wisdom for meta-modernism and its politics: that would be wise.

Küpers: As a counterforce a new sustainability-oriented '*enlightenmentality*' can help overcoming conservatism and resistance of special interests, via decentralising the overconcentration of power, towards '*glocal'* governance, political subsidiarity and direct democracies. Such planetary orientation may contribute healing from the myopia of narrow short-termist towards more integral and long-term outlooks and solidarity, community based living help getting out inertia of complacency, asking critically and responding practically to the question how shall we live how to co-create congenial meaningful and fulfilling lives, all leading towards genuine transformations as fulcrums in time, situated in places, but now planetary!

Paul Raskin: I would call this the great transition as a "*Journey to Earthland"* (2016)?

Yuval Noah Harari: Concerning the status of homo, do we now again aim to upgrade humans into gods, and turn homo-sapiens into homo-deus?[31]

Facilitator: There are many open questions: Do we need to relegate humanity back to one of many natural species, thereby rejecting any claims founded on anthropocentric dominance, or extend subjectivities beyond the human species (Wolfe, 2009)? Do we need re-centering on the human(ism) or an anthropo-decentering (Küpers 2020) and moving beyond the human towards anti-, post-, trans-, or meta-humanism (Ferrando, 2013; Miah, 2008)? What would it then mean to examine discourses and practices to uncover inherent humanistic, anthropocentric, normative notions of humanness and the concept of the human, versus exploring possibilities of posthuman-centred ways of living and enacted convivialities?

---

[31] **Yuval Noah Harari:** Do we now (again) aim to upgrade humans into gods, and turn Homo sapiens into Homo deus? Moving from humans who worship gods into humans who become gods… Mythologically and historically, playing god – apotheosis – is an old recurring theme. You might ask: How is it envisioned today for which kind of future*?* Well, by bioengineering and cyborg-technology and production of non-organic entities*?!* What we can observe is that technology overtakes religion; the fear of nature transmutes into an unprecedented capacity to control nature. Are we humans doomed by superhuman biological or computational machines? Our capacity to manipulate two fundamental forms of information – the biological and the computational, the byte and the gene – will thus result in the birth of superior beings who will ultimately overrun our world. In my reconstruction of "Sapiens: A Brief History of Humankind" I discussed the genetic, anthropological, cultural, social and epistemological (macro-)history of humans over the last 100,000-odd years processed by three broad "revolutions." The first, the "cognitive revolution," resulted in humans acquiring the capacity to think, learn and communicate information with a facility unprecedented in the animal kingdom. The second – the "agricultural revolution" – allowed humans to domesticate crops and animals, enabling us to form stable societies and intensifying the flow of information within them. The "scientific revolution" came last. Humans acquired the capacity to interrogate and manipulate the physical, chemical and biological worlds, resulting in even more potent technological advances that surround us today. Why should we assume that sapiens are the end of the evolutionary line? What comes next? Are we given ourselves over completely to machines, to re-engineering bodies and brains? This dystopian vision rests on many questionable assumptions. For example, that we don't have free will, and never did, or that humans will somehow shed their collaborative, social instincts which, are what made us so successful in the first place.

We're going to need not only new conceptual understandings, but new and different imaginations, images, imaginaries, myths and stories. We are in urgent need for new *INTER*-relationships to our self, to other selves, to plants and animals, relating to nature as part of us! Likewise what is called for a ways of relating to 'proto-wise' traditions of human culture about what makes live good, just and truthful those that have been suppressed, marginalised or forgotten by our capitalising and commodifying systems of appropriation? What does it mean and imply to live a meaningful live, while facing death? Who are we all as a communal and collective existence? Not only asking: What does it mean to be human? But: What is our vision of conviviality of 'hu-(wo)-man' and 'more-than-human'? What role might the digitalisation and digitalised (trans-)formation play in all this?

We cannot respond to these questions and underlying quests here anymore. But in any case, for all these inquiries, we need more of these forms of encounters and dialogues, not only between philosophers, scholars and scientist, but between people in public spheres…

To regain wise forms of daring and wayfaring may then become, as described in mystic and Asian wisdom traditions, an awakening that allows to sense and see 'truthfully' through. This implies seeing through misleading orientations of illusion and ignorance, and through the dark veils of habitual comprehension towards an immanent bodied-spiritual self-transcendence… Perhaps this also helps practically to cultivate a *'well-be(com)ing'* in and through organisations (Küpers, 2005) of a sustainable and wiser praxis, practices and actions as well as a responsible engaged 'letting go' (*Gelassenheit*[32]) as a lived, living and enlivening enacting of the 'Art of Wisdom' (Küpers, 2013).

As such art an embodied wisdom is personal and professional artistry that integrates a refined sensibility, creative imagination, implicit knowing and explicit knowledge, poignant acuity, experiential and reflective learning and the ability to make 'optimal' micro-, macro- and meta-judgements about the feel and significance of the particular and given circumstances effectuating action characterized by virtuosity and excellence. This all serves a careful concern for the common good and transforming today's personal, social, cultural, political and economic realities into a more equitable, peaceful and enjoyable existence and evolution, a lived and living, convivial 'Sapienism'!

---

[32] Such Gelassenheit is not a consoling form of quietist tranquility, a kind of Schopenhauerian release from the turmoil of existence and the cravings of the will, not as one that is one of promotion of contemplation as a way of life amounting to a decadent form of nihilism, or a flight from the realities of existence! This 'Gelassenheit' translated as letting-go, serenity, composure, detachment refers to a non-objectifying ethos of active and ongoing passivity, to an accepting by letting-go, implying an abandonment of habitual, representational and appropriating orientations. In this letting-be of things, the one who acts wisely does not attempt to manipulate, master or compel things, but instead let things be in their vital nature. More importantly, 'Gelassenheit' is not about the indifference or lack of interest in things, but rather an 'engaged letting.' Entering a modus of letting-be is realized through a receptive waiting and listening, thus more an active non-doing, rather than a willing and controlling business of mastering. It moves specifically from representational and calculative modes, via presencing, meditative thinking towards more poetic relations. Following an ethos of 'Gelassenheit' the wise cultivates remaining present, responsive and ethically responsible as well as connected to the 'materio-socio-cultural' practices and worlds they participate in and co-constitute while detouring (Küpers 2015).

May the sagacious 'owl of Minerva'[33] take her flight, not as a fight at the dusk of the Western philosophical tradition, as Hegel would have it, but – via a post-Eurocentric[34], global and local thus 'glocal' and inclusive integration as a common planetary hi-story – towards into the emerging faint silver lining light of a dawn in the clear-obscure 'a-*wake'* of daring to 'be(come)ing' wiser…

[33] The metaphor of the flight of the owl of Minerva refers to a quote in the concluding paragraphs of the Preface to his Philosophy of Right, by Hegel where he examines the role of philosophy in prescribing principles on how the world ought to be. 'When philosophy paints its grey in grey', Hegel writes, citing a part of Goethe's Faust, "A shape of life has grown old, and it cannot be rejuvenated, but only recognized by the grey in grey of philosophy; the owl of Minerva begins its flight only when the shadows of night are gathering" (Hegel, 1991: 23). "if we are to avoid that 'cold despair' which confesses that 'things are bad or at best indifferent, but that nothing better can be expected here', we need to do more than simply watch the owl of Minerva spread its wings at dusk. We might also need to *tell her where to go* by identifying appropriate principles orienting moral and political reform" (Ypi, 2013: 131).

[34] Contemporary Enlightenment calls for global integration as we need more inclusive post-national, global and less Eurocentric approach. But as much as there might be moves towards a Global Enlightenment in all its ambivalent legacy there will be *Global Counter-Enlightenments* existing and emerging in different times and places (Lok & van Eijnatten, 2019: 415).Various global crossings, encounters, exchanges, transfers, appropriations and diffusions are at the root of the European Enlightenment, which can itself be defined as an accelerated and enhanced "movement of ideas across borders and overtime" (Nussbaum, 2003: 2), rather than as a fixed set of genuinely European ideas. ….European travellers, emperors and scientists didn't come to the extra-European world with ready-made models of an Enlightened society, but rather, the global experience is at the root of concepts that are generally seen as genuinely European and/or Enlightened (D'Aprile, 2019, p. 394).

A Personal Introduction

I met “Hanzi” for the first time in 2011, right before the founding meeting of the European Consortium for Research in Adult Development (ESRAD) in Lund where the main “Hanzi” author was studying at the time. He had contacted me over Facebook in response to some entry on integral politics and adult development, a passion that we both share. And so we decided to meet a few days before the ESRAD conference, to exchange ideas and visions about how to transform politics into an integral direction.

Already then, the young Swedish sociologist (he asked me to remain with the pseudonym) was close friends with his future “Hanzi” co-author and sparring partner, an equally young Danish historian and philosopher, who later founded “Fri Tanke” publishing. At the time, the two of them, together with a couple of other friends, had put together a manifesto of integral politics, hoping to develop the foundations of a new political movement or party around these ideas in Sweden and the Nordic countries. As I had been actively involved in the first integral party, founded in Switzerland in 2008, we had plenty to talk about.

While I met Hanzi 2 and the rest of their gang only briefly, Hanzi 1 had kindly offered to be my host at the ESRAD event, which he also attended himself. So over about a week of co-working and living, multiple impressions added up to a picture, in particular that of a bright and ambitions young thinker, thrilled by integral and developmental models and the prospect of infusing these into societal reality. At the same time, he also shared a couple of deep personal issues and challenges which made clear that – by necessity – he was working as hard on the level of psycho-emotional processing and personal transformation as he was in the area of theory building. And he had strong claims and solid views in both areas.

One of the topics that was present in our conversations already then was the strong green-social-liberal political mainstream in the Nordic countries, in particular Sweden. Yet, while probably being culturally ahead of things in many other western countries, the question was if, or to what degree it was actually ready to embrace “integral” ideas, for instance those of vertical growth and

development in individuals and societies. For the “Hanzi” team, consisting of critical social scientists, one of the main challenges was therefore how to find an appropriate language and approach for bringing “integral” into the discussion without triggering the typical reflexes of the “green meme”. The Listening Society is (part of) the answer that the authors came up with: a contentious, provocative, sometimes even offensive invitation to dance, debate – or fight – towards what they imagine to be a typical “green meme” intellectual reader. Their recipe is to mix deep sincerity and thorough analysis with playfulness and irony.

Part of the reason why they decided to publish their book under a pseudonym supposedly was, first, to somehow go beyond a common reflex of mainstream publishing and academia, namely to claim praise for individual work. Instead, the author(s) suggest that transcending certain natural impulses of the ego is an important feature of the to-come meta-modern phase and stage of societal development. Also, “Hanzi” seems to make it easier for them to ride their attack against the green meme mainstream, a confrontation that purposefully transgresses the usual moral boundaries of academic politeness and respect time and again.

At the same time, “Hanzi” also shares quite a lot of detail about his own (in this case, Hanzi 1’s) life trajectory and experience (“Who is Hanzi Freinacht?”, p. 5ff.), including his daily schedule and routine when writing the book over a year or so in a chalet in the Swiss alps. This personal background does indeed reveal some of the deeper motivations behind certain aspects of the model laid out later in the book, in particular the comparatively strong focus on subjective states and depth (“My friend, I write this from a subtle longing of my heart”, p. 6). So, what is this longing about that a listening society is the answer to?

The Listening Society – Resources, Vision and Main Contents

The term “listening society” refers to the idea of a societal culture of awareness that listens – and responds to the needs of its citizens in a deeper and more holistic way than the current materialistic one, including the deeper longings of body, mind & soul. The book spells out elements of a vision revolving around how we could “create and reproduce a society in which the average human life experience is more emotionally satisfying and spiritually productive” (p. 95), assuming that more happiness, in turn, will cause people to give something back to society and thus lead to better communities, more sustainable economies and a healthier planet. The basis for this is a world view and epistemology which Hanzi chose to call “metamodern,” drawing on theorizing in the fields of art, aesthetics, philosophy and culture theory. Even though the book’s major resources and inspiration come from Ken Wilber’s integral model (as one of the authors acknowledged in his presentation of metamodernism at the IFIS Online Colloquium in April, 2019), this choice of terminology is presumably also motivated by the consideration to reach a wider audience in the academic mainstream this way.

The term “metamodern” is borrowed from the Dutch art scholars Timotheus Vermelen and Robin van der Akker who noted a new trend of “pragmatic idealism” in arts already two decades ago. They also describe it as both a product of and a reaction to postmodernism, embracing “doubt, as well as hope and melancholy, sincerity and irony, affect and apathy, the personal and the political, and technology and techne." (Levin, 2012). “Hanzi” now sets out to add more specific meaning to the term, in particular that of a developmental stage and related philosophy, thereby aiming at making the concept travel to the social sciences and political practice.

So what is the essence of this socio-political metamodernism and how is similar to or different from "integral"? To what degree are its contents borrowed from integral or actually go beyond the latter in substantial ways? Even though these questions are not explicitly addressed in the book, they were at least ever present in my reading.

Hanzi himself proposes three different definitions of metamodernism (a cultural phase, a developmental stage, and a philosophical paradigm, p. 362f.). Readers interested in terminological fine-tuning will have to go into Hanzi's appendix where he offers a condensed version of his conception of the metamodern paradigm (p. 363 ff.). My own reading is that metamodernism as outlined in "The Listening Society" is one possible interpretation, expression and/or application of integral thinking – even though the author(s) might not subscribe to this reading.

Given the Hanzi authors' background in the social sciences, what they do offer beyond the integral model per se are elements and foundations of a vision for a more integral society and some political choices and changes of perspective that could help to bring it about. On the level of modeling strictly speaking, there are some interesting terms and categories that one has not seen or that are used differently in Wilberian models. However, I don't see these pointing at completely new dimensions that integral philosophy would not have been aware of before. Hanzi's metamodernism rather comes across as a "reframing" of integral for a post-modern (academic) audience, which it explicitly speaks to in both tone and style, and in view of addressing more specifically socio-political challenges. That, of course, is of value in its own right, given that much of the academic mainstream is currently struggling with late forms of modernism (for part of the sciences) and post-modernism (for the humanities and much of the social sciences), as well as with their paradigmatic contradictions and limitations preventing more efficient action on pressing global issues.

So let's spend a few words on Hanzi's language and style first. In line with the identification of sincerity and irony as a core characteristic of metamodernism, The Listening Society displays a mixture of these two qualities itself. More precisely, it takes the reader on a roller-coaster ride between sincere high-level theory and epistemology on the one hand, and a way of addressing the (presumed) reader in a personal dialog that is sometimes witty and playful, but as often also straight and provocative ("the less intellectually gifted readers are by now conjuring up ways to get out of the stranglehold", p. 11; "in case you still don't get it…" p. 351), partly de-constructive ("bullshit," p. 60; "science is a whore dressed up as queen, a jester posing as king," p. 20; "wisdom […] is a crap variable," p. 300) and sometimes purposefully insulting ("my theories deeply insult the prevailing moral intuitions. I spit straight in the face of their political identities […]"; "it is the solemn duty of the philosopher to piss on all that you hold dear and sacred, to show you that your gods are false", p. 9; "frankly, my dear, I don't give a damn about your feelings; if [you are mad at me for insulting you] you should probably put down the book, go take a long, hard look at the mirror, get over yourself, ad re-read the last section," p. 19). Of course, this style is an integral part of Hanzi's message and strategy. He wants – or (thinks he) needs – to be provocative in order to make himself heard and get the message across: That mainstream postmodernism is in a dangerous dead end and should start noticing the new paradigm that is knocking at the door. It should start acknowledging that metamodernism is much more effective in addressing the pressing needs of our times and therefore deserves exceptional intellectual-emotional efforts, even if this might appear painful to the holders of certain current belief systems.

One can discuss whether the book has always chosen the right means to this end. Yet, it does essentially walk its talk when it comes to the symphony of a rather colloquial (personal, dialogical) style, theoretical depth, playfulness and sincerity, or as Hanzi puts it, “sincere irony” (p. 27, 107). The fact that it is generally very well edited, with almost no language and spelling errors or typos, also demonstrates and emphasizes the sincerity part of its message.

Giving a complete summary of the book’s rich content would go beyond the limits of this review. I will nevertheless try to give some insights into Hanzi’s core ideas and some of the inspirations I have gained from the reading.

The Listening Society is conceived as the first book of an envisioned series of several more to come. In the book itself, two more volumes were announced, a developmental perspective on history, including core principles of metamodern politics (n° 2), and a volume on “the Nordic ideology” (n° 3 – this has actually just been published in May 2019 as number two), featuring developments in the Scandinavian countries. According to the author, the latter have come particularly close to a metamodern political culture, and are thus particularly well prepared for implementing it. Meanwhile, however, the main Hanzi author has also been talking about a series of up to six books that seem to be taking shape in Hanzi’s mind. Well, let’s see what comes next.

The series’ overall focus is on politics and transforming society based on an integral, or, in Hanzi’s terms, metamodern paradigm. This includes an analytical perspective on historical and present socio-economic developments and a multidimensional vision of how (a metamodern) society could take responsibility for the development of its citizens. As Robert Kegan has coined the vision of a “Deliberatively Developmental Organization,” *The Listening Society* spells out the first steps towards the vision of a deliberatively developmental society.

In this context, considerable space is dedicated to the idea of personal happiness in a broad sense of the term (p. 73ff.), which is conceived as a worthwhile socio-political goal. This is because happy people whose immediate and deeper needs are met, are more likely to take responsibility for others and the society as a whole. “Happy people are more productive in profound and complex ways” (p. 78). Moreover, the term *listening society* refers to a new, more complex notion of welfare – one that by supporting peoples’ development not only facilitates better choices and healthier, happier lives of its members, but thereby also helps to actually saves costs which would otherwise be generated for various kinds of treatments and by a considerable number of collateral damages (p. 84). In Hanzi’s words: By “deliberately and carefully cultivat(ing) a deeper kind of welfare system that includes the psychological, social and emotional aspects of human beings (…) the average person (…) becomes much more secure, authentic and happy (in a deep, meaningful sense of the word); (…) such people can then recreate society in a myriad of ways, solving many of the complex, wicked problems that we are facing today” (p. 72).

While the book does give some examples as to how this could happen, drawing on happiness research and an impressive list of references from meditation research documenting meditation’s multiple benefits (pp. 96-103), it seems to be primarily concerned with laying the groundwork and seeding the broader, overall vision than with defining concrete strategies and steps. The vison itself is extended to a larger systemic level, with societies competing for being the most listening one, as a "competitive edge in the global economy", so to speak (p. 93). With "human development driv(ing) economic growth, (this) deeper welfare system is necessary" in order not to "be outcompeted by other, *more* listening societies where citizens truly do thrive" (ibid.).

The Metamodern Model

In a nutshell, the metamodern model is essentially introduced as a combination of four dimensions that Hanzi presents as independent of each other: cognitive complexity, cultural code, subjective state and depth. The first two dimensions: personal (individual) cognitive development and socio-cultural development (or "code") come across as elements from the Wilberian integral model. Cognitive complexity is essentially presented based on Michael Commons' Model of Hierarchical Complexity (MHC); cultural code appears to be a modified version of Spiral Dynamics. The two other dimensions, state and depth (p. 158), differ from the Wilberian integral model to some degree, even if probably less substantially than with regard to their relevance and positioning in the Hanzi model. (Unfortunately, Hanzi's model is not visualized anywhere in the book, so that the reader has to mentally build it up from the text on her own). Let's look at each of the dimensions successively, with the two developmental ones going first.

Cognitive Complexity: The fact that Michael Commons' MHC is given a particularly prominent place as "the by far most scientifically viable and consistent [model], and the one that indisputably has the strongest empirical evidence" (p. 171) is less surprising, given that the Hanzi author has spent several months working with Commons in the US after completing his dissertation. Since the MHC is well known to IR readers, I will not bother summarizing its merits and contents, but rather report some of the dissonances I stumbled over during my reading. While there is no doubt about Hanzi's assertion about the solidity and mathematical basis of the MHC, I had to read twice when it comes to some of Hanzi's other claims. For example that "Commons is the only one that has discovered one [i.e. cognitive complexity, E.F.] of the [Hanzi's] *four* fundamental dimensions of development" (p. 173) – what about the Piagetian foundations of cognitive developmental research in the 1930s?

Equally irritating is Hanzi's treatment of essentially "all of the (other) holistic adult development theories" as "fail(ing) to grasp quite what it [development] is" (p. 172). Without any mention of the specific goals and approaches of the respective theories, Hanzi somewhat seems to criticize everything that is not MHC, precisely for not being MHC. For instance, he claims that renowned researchers of ego development such as Robert Kegan, Jane Loevinger and Susanne Cook-Greuter "mix things up" or "blend in issues of personality into the different stages and spice it up with a bit of psychiatric diagnostics (where the lower stages are described as psychopaths, more or less)," p. 173. – Excuse me?! Several similarly bold claims about other authors are based on similarly fluffy grounds that often raise more questions than they answer.

There is no discussion of the distinction between hard and soft stage models and related debates on measurement (see Stein & Heikkinen, 2009), nor of their respective merits and limitations. Just plain judgement. What's worse, Hanzi claims that "the main problem of many of the adult development theorists, from Jane Loevinger and Susanne Cook-Greuter to Robert Kegan, stems from the fact that their authors are at this [the MHC systematic] cognitive stage" (p. 201) (sic!).

Neither does he elaborate what “problem” he is referring to, nor does he provide any evidence for his claim about the developmental stage of the mentioned researchers. In a private communication with the main Hanzi author, he explains that the above claim is based on their “putting development into one scale which is one-dimensional, and driven by one central logic (one system, rather than several systems with differing properties).” Hanzi sees this “tendency to view everything as "ONE system" (as) a hallmark of systematic stage thinkers” (private communication).

While lacking empirical evidence is a reoccurring theme in the book, Hanzi remains relaxed: “I don’t have the data to prove it, but as far as I can tell…” (p. 337); or: “parts of the book are based on arguments and generalizations that you must weigh and consider with your own rational and emotional faculties, much like the arguments of other social theorists. (…) Social theory is where science and common sense meet” (p. 20).

Another irritation arises when Hanzi complains that “many of the neo-Piagetians (…) tend to be relatively narrow researchers who don’t fully take stock of the social implications of their own theoretical work” and therefore “fail to understand the vast consequences of their theory for understanding society, and the world at large” (p. 385, footnote 80). While it is true that most adult development researchers “are lousy political sociologists,” why accuse them of their choice of topic and academic focus if they have never claimed to deliver a sociological analysis? True, “that is another reason we need Hanzi” (ibid. 385, fn. 80). At the same time, Hanzi would not have been possible without the work of all these previous researchers in the first place. So, while claiming that all the “solid science” is on his (and Commons’) side, Hanzi fails to apply a basic principle of scientific integrity when it comes to paying due credit to the achievements of other research traditions. We will come back to this and the problem of empirical back-up.

The second developmental dimension in the Hanzi model of metamodernism is sociocultural development or, as he puts it, cultural code**,** evolving through a range of symbol stages from A (archaic) to G (metamodern). Here again, the author draws heavily on work by preceding researchers, namely Jean Gebser, Clare Graves and Don Beck/Chris Cowan’s Spiral Dynamics. Even though he slightly modifies some of Beck/Cowan’s stage names (“Faustian” for “Red” or “Imperial” and “Post-Faustian” for “Blue” or “Mythic/Traditional” and calls the overall stage category of the cultural code dimension “meta-memes,” there is no substantially novel quality claimed for these stages description-wise. Given that the Hanzi model is not based on evidence of its own, this is not surprising.

At the same time, Hanzi uses and introduce several terms, namely value memes, symbol stages, “meta memes” and, later in the book, “effective value memes,” the definition – and distinction of which remains somewhat unclear. While the contents of the seven memes/stages appear to be what we know from the SD/Wilberian models, the almost synonymous use of some of these terms adds some conceptual confusion. For clarification, Hanzi, as often in the book, refers to further forthcoming volumes with a promise of more detail. (In this case, *The 6 Hidden patterns of World History* is announced to discuss “the historical development of meta-memes, i.e. the overall patterns that set the logic for what memes can be expected to show up at a certain stage of societal development,” p. 213). Later on, we learn that the concept of “effective value meme” is in fact a new, way more complex variable, first mentioned, but only vaguely explained on p. 174 as an “overall pattern” generated by the relationship between Hanzi’s four dimensions *complexity, code, state* and *depth.* Here again, the aim is high, namely to provide “a more stringent version of the

Spiral Dynamics model, solving its main problems and clearing some of the confusions around it…", while its clarification and operationalization is postponed ("each of which [the four categories] will get simplified but workable definitions…," p. 174).

Before we move over to the two other dimension of the model, what I do find helpful in view of the first two is the analogy of using the terms "hardware" and "software" for cognitive development and cultural code respectively (216ff.). Hanzi argues that it needs a certain cognitive stage (as the necessary "hardware") to be able to function properly at the respective level, while the cultural code of a social context can be adopted through socialization, like "downloading" a software content, provided the corresponding hardware/cognitive level has sufficient "hard drive space". This illustrates that with a given kind of hardware (or, more precisely, operating system), only equal or lower level software can be run successfully, whereas higher level (more complex) software can possibly be downloaded, but might not function properly based on the existing hardware (operating system, *my term, EF*).

This analogy is a nice illustration of the differences and interrelations between individual and collective/cultural development. An individual that is born and socialized into a certain culture, and hence is exposed to that culture (has the *software* available and downloaded), but will interpret and run it according to their own currently operating hardware/operating system. Stephen Chilton (1988), in his Neo-Piagetian account of political development, has formulated this relationship in view of what has become a frequent challenge in the area of democratization politics: transferring democratic institutions to non-democratic environments. Chilton states: "Unless the institution's structure is preserved by people at the appropriate stage, the institution will regress to less developed forms" (Chilton 1988, p. 88).

In this sense, Hanzi's chapters on the development of "cultural code" (also called "symbol stages") and on "language travelling through history, picking up new symbols and meanings as larger societies and more complex interactions between greater numbers of humans over greater distances emerge" (p. 223), are a nice reframing and adaptation of developmental theory to social science discourse. This is of value in itself, given that the latter appears to be one of the main target audiences of the book.

So let's now turn to the two other dimensions that are introduced as core elements of the metamodern model besides cognitive complexity and cultural code: subjective state and (psychological) depth. To readers familiar with integral modelling, it comes as a surprise that Hanzi presents these as the "inner dimensions", as opposed the two former ones. According to the author, the developmental dimensions describe "a kind of 'exterior' reality, meaning that they can both be intersubjectively recognized and, in some sense, 'objectively' studied" (p. 249). While he sees the two developmental dimensions as referring to "the organism's behavior", he refers to state and depth as "the organism's own inner experience". This, then, is suggested as a cure to a claimed "inner dimensions blindness – the failure to recognize and understand the primary importance that peoples' inner lives have in society" (ibid.).

Note that Hanzi does not make reference to Wilber's zones and the integral methodological pluralism derived from them, and that he only mentions phenomenology very briefly. Therefore, one has to assume that all of the latter seem to not suffice him to cover what he is after – up to experts in phenomenology to judge whether his own modelling (see below) adds substantially new insights and better ways of conceptualizing things here.

By “subjective state,” Hanzi refers to “higher” and “lower” inner states of being. They are claimed to be different from emotions, but rather something “more fundamental” that includes “some kind of sum or totality of how we feel” in each moment (p. 254). As an ordering principle for subjective states, he then comes up with a scale from 1-13, reaching from lower states (“hell,” “horrific,” “tortured,” “tormented”) to medium states (“very uneasy” to “joyous, full of light”), up until the high states (“vast/grand/open,” “blissful/saintly,” “enlightened,” p. 260).

Reading chapter 12 on subjective states, one starts to sense that this (and the following) dimension are of particular importance to the author for personal reasons, and that these insights are the product of his own inner growth process. In fact, he does share some biographical and family background in this regard: “During most of my adult life, I have been followed by a sense of tragedy, a subtle but pervasive sadness… (…) the aching heart became the main engine of my life’s work” (p. 6). So while he has a whole backpack of deep difficult experiences here to draw on, that have apparently not been adequately addressed by other/integral models, Hanzi also concedes that “these fields have yet to produce a systematic theory of development equaling the MHC” (which, as mentioned above, he considers as the most scientifically reliable model, p. 249).

Different from the stage descriptions in the first two developmental dimensions of the model, there is no comparable description of the 13 states, either from personal experience, literary accounts or other sources. Moreover, Hanzi suggests that one can only really understand states that one has experienced oneself (p. 272). This, of course, not only makes it difficult to come up with “objective” scaling and modeling strategies regarding the different states. The author limits himself to the assertion that “even if my scale isn’t proven, it is certainly testable: you would need to device a way of measuring physiological correlates and perhaps peoples’ self-described experiences” (p. 395, fn. 129). In any case, the question remains open, on which grounds the 13 state model has been built by the author. Has “Hanzi” himself – or people he draws on – actually experienced the full spectrum that he so clearly (yet vaguely) lays out in his book? Or, since at some point, he admits that he hasn’t, do they come from “common sense,” single intuitive examples, or solid scientific research? Based on his own premises and standards at least, it becomes close to impossible to verify Hanzi’s model of 13 subjective states empirically.

But anyway, let’s assume they were meaningful categories. Because we need them to understand the fourth fundamental dimension of Hanzi’s model, the idea of a spectrum of states that a person has experiential access to, which he refers to as “depth.” Even though Hanzi claims that the four dimensions are independent of each other, depth obviously has an immediate relation to subjective states. He conceives depth as a product of the range (and thus number) of subjective states that one has experienced out of the above described spectrum. The more states an individual has experienced, the greater their psychological depth. Depending on whether one’s experience includes more of the lower or more of the higher states, Hanzi speaks of “dark” versus “light” depth. Just like for states, he stresses that “we are generally only capable of recognizing the forms of depth that we have developed ourselves” (p. 298). At the same time, the empirical basis of the emergence of this dimension of the model remains unclear.

Again, one senses that not only is conveying this dimension particularly dear to the author, but also that the depth chapter is likely written on the basis of some deeply transformative personal experiences, including ones of existential suffering of his own and people he knows. For instance, he points out that "a lot of the less-than-fully-functional people in society tend to out-depth most of us (…). Broken and crazy people, for all their limitations, often live in greater worlds; they have walked to hell and back. A lot of them just stumbled on their way back" (p. 288). This theme is touched at various occasions. Examples include experiences from the main Hanzi author's family and the observation (apparently also based on personal experience) that a therapist should possess at least the same depth as their client in order to be able to help them (p. 288).

Considering the passion with which Hanzi explores this dimension ("depth as beauty, mystery and tragedy;" "only a sense of tragedy can drive us to work for the wretched of the earth: loving until it hurts (…), only broken hearts can save the world" (p. 293), it is safe to say that adding this dimension to next-stage modelling is one of the core foci and concerns of the book.

The importance of depth is additionally stressed by the fact, that Hanzi equates depth with wisdom ("wisdom is great depth, plain and simple," p. 302). At the same time, a whole chapter is dedicated to a discussion of the idea of wisdom – if not the whole body of wisdom research. As far as the latter is concerned, Hanzi's positions resemble those of his discussion of the "holistic" developmental models: The research in the field uses different approaches or doesn't consider his own dimensions, hence it's worth nothing: "The wisdom people haven't done their homework (…), they haven't figured out exactly what they are talking about;" wisdom is "a crap variable" (p. 300). And unfortunately, Hanzi again combines his critique with broad and cloudy judgements about a number of other writers, for instance Eckhart Tolle ("kind and wise, but poorly educated and not very clever," p. 302, 278), to mention only one example. Unfortunately, the author does not explain how he arrives at his evaluations of specific people's developmental stage, level of depth etc., but seems to call upon the reader's trust in (his, Hanzi's) common sense: "Social theory is where science and common sense meet" (p. 20).

Despite these weaknesses – and notwithstanding the difficulty of measurement – the depth category can be considered as the most original idea in the Hanzi model. Moreover, in this regard, the author's particular interest seems to be to redefine the interrelations between the four dimensions, more precisely, to have state and depth acknowledged as equally – or even more – important than structural cognitive and cultural development. While development is a goal in all four dimensions in order for individuals to mature Hanzi's own preference is on what he calls the inner dimensions, i.e. state and depth ("if I had to choose, I'd go with state," p. 348).

He gives multiple examples of people with high depth despite low complexity, as if to point out that what is commonly appreciated as an indicator of personal development in integral circles, namely cognitive and/or ego development, is only part of the story. On the one hand, this preference seems to imply that people whose personality profiles show high depth (i.e. wisdom, life experience etc. or spiritual development) are of particular "value" for society and thus, should be given more appreciation, regardless of their cognitive complexity. On the other hand, Hanzi rightly points out that development generally requires a benevolent environment and, ideally, a minimum quality of state (high states "have lasting impact on our overall psychological development," p. 275). So the fact that relatively high/positive/happy states can be brought about quite easily through some sort of support or "nudging," opens up a worthwhile field of activity for Hanzi's metamodern politics and society: “Just imagine how differently society would function if many more of us were in higher states a larger portion of the time” (p. 270).

Altogether, Hanzi suggests a model that combines the four dimensions – and even allows high depth to “outweigh” low complexity in a person’s overall developmental profile: “If we are roughly correct, all of these four dimensions should correlate strongly with people's value memes; in fact, they should together make up the value meme, more or less” (personal communication). In the book, Hanzi therefore introduces the new concept of “effective value meme (evm)” which he defines as “a kind of average between your complexity, code, state and depth” (p. 310). In other words, the higher one scores in each dimension, the higher one’s evm.

Obviously, the term “development” takes on a different meaning when we turn from structuralist stages to inner states, and Hanzi himself does concede the difficulty of measuring the latter. What he does not spell out at all though is how the four dimensions can actually be translated into one overall indicator or category. While the idea that an individual can have low complexity and high depth is very plausible, it is not made very clear, how “these four dimensions work together to generate overall patterns” (the evms). The book leaves open, what those patterns might look like in practice, and how they could be meaningfully modelled on a higher, more complex level, beyond just summarizing and adding up someone’s scores in each individual dimension (p. 174).

In view of the relation between states and stages**,** Hanzi himself just states that they are related, but don’t predict each other (p. 270), and that “states are more volatile and easier to affect than stages of cognitive complexity (p. 271). So far, these things are well-known, not least from Wilber’s work in this area – with which Hanzi does not seem to agree with though: “Wilber’s model comes closest to understanding these issues. He speaks of two kinds of development: one of spiritual states and one of cognitive stages. But his model (called the Wilber-Combs lattice) is still spaghetti” (p. 173). Eh…?!

General Comments

This, together with a couple of sometimes very harsh critiques of other authors and their models lead us to some final, overall comments on *The Listening Society*.

The book is definitely inspiring reading to anyone interested in integrally informed politics and probably a long overdue wake-up call for postmodernists, with its convincingly laid out claim that “there is no safe political position” (p. 151) and that it’s time for postmodernism to face its own inner contradictions. It also contains convincing pieces of analysis when it comes to reinterpreting the evolution of political governance and socio-economic conflicts over the past 2-3 centuries (finally an integrally informed sociologist!), as well as numerous worthwhile ideas helping to conceive ways for transcending the left-right divide and other challenges of metamodern/integral politics (p. 45). Part of the more concrete sections is Hanzi’s description of the Danish political party Alternativet (The Alternative) which is trying to put elements of these new approach to politics into practice since 2013 (chapter 5).

At the same time, what some have considered a “refreshing” strength (namely “that the ideas of the books are robust but not so carefully fine-tuned as to amputate capacity for impact,” see Hilary

Bradbury's recent review on the Metamodern mailing list) also appears to come with some noteworthy weaknesses. I will point out three of them below.

First, the choice to depart from more a conventional tone and style in favor of what Hanzi calls "sincere irony" can be understood and justified by the declared purpose of the book. However, in my reading, the text does not always walk its talk when it comes to displaying a "listening" attitude towards other contributions to the broad field of metamodern, developmental, integral and other streams of research. When talking about other authors (i.e. developmentalists and wisdom researchers), Hanzi often takes a rather judgmental position, instead of paying credit where credit is due. In this sense, I didn't particularly experience Hanzi's book as a "listening" exercise; his universe does not demonstrate the proposed "youniverse" that sees and appreciates everyone else's efforts. Despite repeated self-ironic confessions à la "we are probably, after all, mistaken" and his explicit "ironic smile at our own self-importance," Hanzi's overall tone comes across as just a bit overconfident. It sometimes also recalls discourses around making one's own tribe "great again" – by bashing other communities, in this case, the integral one, for example. Notwithstanding its ironic stance and its legitimately provocative call for action, the book could display a somewhat healthier degree of sincere scientific humility which, IMHO, can also be seen as an indicator of personal and spiritual development.

For instance, while Hanzi is very explicit about his own model (and the metamodern perspective) being the best and "most powerful theory" currently available for explaining the world ("only the Metamodern value meme can see the world with a sufficient sobriety," p. 332) and about his favorite MHC as being the most scientific and consistent possible methodological approach for this endeavor, he dedicates much less space to other systems than the MHC. Quote: "We don't really have to bother with going through the other theories of adult development; I should only briefly point out that they don't really work…" (p. 346). At the same time, he tends to remain rather vague about the "weak spots" of other theories, often failing to back up broad claims.

Sometimes, this raises questions as to the author's understanding of the respective models. Take for instance Hanzi's claims about Robert Kegan's and Susanne Cook-Greuter's personal cognitive stage and depth based on the design of their theories. He claims that they are functioning at the (MHC) systematic level, because "they both insist upon putting development into one scale which is one-dimensional, and driven by one central logic (one system, rather than several systems with differing properties)." While it may be true that the "tendency to view everything as 'ONE system' is a hallmark of systematic stage thinkers", there is no distinction between the person and their model, let alone a proper analysis of personal stage. While I myself only intuitively doubt Hanzi's evaluation, a colleague who has personally worked with both Kegan and Cook-Greuter more intensively, gave the following comment: "I don't think either of them is inherently at the systematic level, they both display too much subtlety, nuance, compassion, humor and so on to just see things that way. At the same time, what a person who only reads their text sees is their 'performance' in relation to the text they read. Given that most of what they might read is aiming to describe and outline a theoretical model, it could appear at this level. So in such a case, it appears the author is conflating performance in a specific context with the person, and this is dangerous" (personal communication).

Hanzi then goes on to claim that "both do, however, have greater depth and state than most of us" and that "people who are higher in depth and state than in their complexity and code" – what does this mean, actually? … “are often tempted towards a ‘holistic’ view because you feel that there is more to the world than your mind can explain (….), and this tends to pressure the mind to accept magical beliefs” (personal communication). He then gives one (disputable) example each for what he thinks is a magical belief, and ends on the assertion that what he has diagnosed as an imbalance of depth and stage (connected with magical beliefs) “is the most common imbalance in integralists.” He further states, that the (non)belief “in magic is a major difference between integralists and metamodernists.” And according to Hanzi, of course, it’s *the* “integralists” who believe in magic while *the* metamodernists don't, because they “find such beliefs pathological as they can and will curtail any healthy expression of higher stages unfolding in society at large.” Aha.

Second, as to the empirical grounds of Hanzi’s own model, what we find is quite far away from the MHC’s high and clean measurement standards, when it comes to those dimensions that he brings in on top of existing integral models. This is partly due to the fact that inner dimensions such as state and depth are considerably difficult to explore, let alone to measure in any intersubjectively verifiable way. The author is well aware of this weakness (“I don’t have the data to prove it,” p. 337). And while he does mention possible methodological avenues to get a hold of these dimensions (such as in-depth interviews or brain analysis), there is no sign in the book that he has actually engaged in any of the proposed methods, even with regard to a limited number of cases, to test if any of them are helpful in the context of the model. All we get is the confession that “parts of the book are based on arguments and generalizations that you must weigh and consider with your own rational and emotional faculties, much like the arguments of other social theorists” ….

Finally, connected to the first critique, it often remains less clear than it would be desirable, how the proposed new model or meta-system relates to previous, existing ones – and what, therefore, is actually the new aspect or insight (except combining 4 dimensions two of which remain theoretical). For the developmental stages, Hanzi draws heavily on Michael Commons’ MHC (for cognitive stage) and on Spiral Dynamics for what he calls “cultural code.” For the latter, he uses a few new stage names, but does not propose any essentially new contents, let alone empirical data that would suggest modifications to either of these models. When it comes to his understanding of “inner dimensions” and the relations between states and stages, which appears to be a crucial issue to him, there is no discussion of Wilber’s zones, and the Wilber-Combs lattice is, as it were, ridiculed as “spaghetti” (whatever this means). Furthermore, the fact that Hanzi does not provide any graphic illustration of his model (beyond some tables on individual sub-dimensions), but keeps it exclusively textual and thus, linear (-ironic!), does not make it easier for the reader to buy into his specific overall construct of effective value memes.

So, coming back to my initial question about the essence of metamodernism as presented in *The Listening Society,* and about how it is similar to or different from “integral,” the answer has not become clearer. I by all means appreciate the momentum that the book has generated among a broader circle of interested readers in the direction of transformative perspectives for politics and society. (For the moment, the discussion about it seems to be led mainly by male intellectuals though). At the same time, I would still describe it as one *interpretation* – or (the beginning of an) application of integral ideas to these domains (more of that comes in volume 2), maybe also a translation of “integral” for wider postmodern audiences, which is of value of course. I see few substantially new ideas or concepts though, that have not somehow been present in the writings of other integral authors before. Yet, I do see a powerful vision, a strong sense of urgency to “get these things out into the public," and I see a growing community of engaged readers, followers and co-creators who seem to have the willpower – or, in Hanzi's words: "the balls" – to go forward behind the flag of metamodernism and implement a next generation of political leadership and citizenry. This by itself, cannot be overestimated.

Many environmental practitioners are aware of the role Aldo Leopold played in the environmental movement in the mid-20th century. Leopold was a forester, a professor, a conservationist, and a writer known most notably for his book, *A Sand County Almanac* (1966). This book in particular brought to light the interrelationships between humans and land as well as the moral responsibility incumbent upon us to honor those relationships.

Leopold's "land ethic" is an expanded definition of the notion of "community" to mean that caring for one another or for the land are not two separate processes but are intrinsically linked. With the threat of a climate emergency looming, this enhanced framing of "community" is desperately needed to create global solutions. Leopold also stressed that caring is often the result of understanding, feeling, and experiencing. Leopold's vision was for people to have open dialogue about the land to conserve it for future generations. While water is a part of the land ethic, is it important enough to stand on its own? Should water be at the center of the community from which all else flows?

An *integral water ethic* is the topic of *Loving Water Across Religions* by Elizabeth McAnally. Her book is educational and a call to action. Specifically, she says, "Recognizing that the amount of water on Earth is finite demands a shift in values; humans need to learn to regard water not as a resource to be exploited but as a source of life to be cared for" (p. 5). I believe her aim is to bring attention to the global water crisis and provoke empathy for water itself through explanations of the intricate ties between some of the world's religions and water. She examines water through the perspectives of Christianity, Buddhism and Hinduism, ending her book with a secular approach to embodying a water ethic.

According to McAnally, our global water crisis manifests in the way we exploit our water resources in some areas of the world and in the way millions of people lack access to clean water and appropriate sanitation services in other parts. In other words, while water covers 70% of earth, 3% of that is freshwater and even less is potable, or water that can be made available to people. Water use around the world has increased. Increased use coupled with threats from climate change leads to even more vulnerable water security in areas of the world already experiencing water stress.

Water is a social issue. Our experiences and connections to water differ around the world. A water ethic would mean acknowledging not only our own reliance on water but others, even non-

humans, reliance on it too. McAnally is asking us to rethink our relationship to water from one of utilitarian to one of interdependence; from instrumental to intrinsic. Can we feel love for water?

McAnnally's approach to a relationship with water would cultivate the subjective experience of water rather than water as a resource, a commodity, a source to be managed and objectively studied. She calls for conversations about water to transcend economics, politics, and science. Valuing water through an *integral water ethic* lens would acknowledge that ecological problems cannot be addressed without also examining social and cultural interconnections. McAnnally points to the intersection of religion and ecology as being ripe to tackle the complexity of today's problems, such as the water crisis. By making explicit the many ways that different religions relate to water, religious and environmental scholars, leaders and advocates can collaborate on future solutions. She focuses on Christianity, Hinduism, and Buddhism.

She states that reflecting upon baptism helps us reconnect to our relationship with water. According to McAnnally, baptism is a "central ritual of Christianity" (p. 51). Because water is a cleansing element, it metaphorically, also cleanses one's soul. Water used in baptism and water used in other elements of a church service is water blessed by a priest, or holy water. The "material substance" of water is just as important as the symbology of water (Robinson, 2013). Protecting the material substance of water is a moral endeavor. In seeing water as part of God's creation, one's relationship to water reflects their relationship to God. In helping Christians see these connections, McAnnally advocates for more attention paid to one's own responsibility to nature.

McAnnally draws from a range of thinking by philosophers and theologians in building her thesis throughout the book. She references ecotheologian Larry Rasmussen's work as it builds off of the existentialist philosopher, Martin Buber's I-Thou and I-It types of relationships. These perspectives argue that we must shift our perspective of water to include the subjective. If water is simply a resource for humans, we may forget or ignore its intrinsic value as part of God's creation. She quotes Pope Francis who says that we must understand that the world is God's loving gift and that we realize and care for our interconnectedness.

Her chapter on Hinduism aims to more explicitly connect science and religion. Commitment to scientific inquiry and loyalty to religion can work together to protect water resources. The Ganges River is worshipped as a Goddess. The metaphor of river as Goddess is part of an integral water ethic where water fosters love. Whereas her chapter on Buddhism advocates for the Bodhisattva[2] within to do one's part in water conservation; She refers to this as Ecosattva. Or, instead we might think of water itself as a bodhisattva, nourishing us, cleansing us, giving us life.

Loving Water Across Religions ends with two chapters that offer both practical and philosophical guidance to implement some of the book's main ideas. She says, "An integral water ethic considers water to be not merely a resource for human ends but a sacred source of life… An integral water ethic supports the cultivation of love and compassion for water and for all who suffer from the global water crisis; in doing so it promotes relating to water as a loving and compassionate being" (p. 155). To realize this ethic, we should try to be fully conscious of the ways we interact with water - in the shower, at the beach, at the sink, and as we quench our thirst. From a religious perspective, water is sacred and as a result, we should honor, respect, and love it intrinsically and for its nourishing qualities.

---

[2] A Bodhisattva is "someone who is full of love and compassion for all human beings, generating awareness of the suffering of others (including non-humans)…and striving for their well-being."

McAnally offers contemplative practices for practicing and nurturing an integral water ethic. From simple actions such as being mindful as we drink a glass of water to a more involved meditation, the practices offered can be used within schools, community groups, and places of worship. I tried one practice called The Bowl of Tears (Macy, 2012) with my early morning environmental studies undergraduate class. Students begrudgingly followed me from our warm classroom to the chilly shore of Pearly Pond. We are fortunate to have our own body of water as the backdrop for our small campus up on a hill. Yet, do many of us fully experience the pond in the way that McAnally's integral water ethic suggests? We drive by the pond, kayak in it, fish from it, and get our drinking water from it, yet, do we love it? Do we have empathy for it? Are we interested in protecting it? Do we see it as sacred? I asked my students and myself these questions as we started the contemplative practice. I asked a student to go to the pond and fill a bowl of water and to place it on the ground in the middle of our class circle. The bowl, I said, represents the tears of the world. As we stood around it, I asked the students to walk to the bowl of tears and place one hand inside if they felt compelled. As they ran the water through their fingers, I asked them to imagine a feeling of love for water and of empathy for those who are suffering from a water crisis. At first, no one moved. I began the practice myself to nervous smiles and averted gazes. We waited. Then one student said, *Ok, I'll do it*. Within minutes all 28 students' hands were wet. They needed the support of one another to support water. Rather than religious devotion, commitment to community and need for acceptance guided the practice that day. I asked for a volunteer to dump the water back into the pond now that we all had felt it. We walked to the shoreline and watched quietly as one student poured the water into the pond. As she turned back to the class, I saw tears in her eyes.

Book Review - Overview

The Future Has Other Plans has been dedicated to "heritage managers who sensed there was a better way to plan but weren't sure how to get there." However, it could be a very useful guide for other kinds of planning professionals who might count themselves in the private sector as developers or in the public sector as civic managers or city planners or as managers in civil society/third sector.

The authors McCool and Kohl have structured their book to give the reader a logical but satisfying path through the realities of both natural and cultural heritage projects. The authors use a mixed metaphor of a (Scharmer-style) U path down the left-hand side of an iceberg of challenges, shipwrecks and messy problems through the shift-point at the bottom of the iceberg U and up the right-hand side into the light of a new paradigm reframing practices toward an holistic/integrally-informed approach to planning.

Part 1 introduces the reader to the realities that professional conservationists face as they operate under three major worldviews: Traditional, Modern and Premodern. This part should resonate not only with the experienced project leader but may horrify the less experienced heritage change agent, as the authors share their professional and life experience from natural and cultural sites around the world. Thus, their reviews of what has been, what is and what longs-to-be is well-informed, clearly described and often keenly illustrated.

Part 2 consists of four chapters, each exploring one of the integral quadrants for the benefit of:

- the Manager's Mind (Chapter 5)
- the Manager's Well-Being, Behaviour and Skills (Chapter 6)
- the Collective Influences on Planning (Chapter 7)
- the Institutions that Serve Heritage Sites (Chapter 8).

These are followed by Chapter 9, that summarizes the journey just completed and lays out the Holistic Planning strategy that the authors propose addresses the many barriers explored in Part 1 by applying the learnings of Chapters 5-8.

As noted below the structure of the book could be strengthened by making Chapter 9 into Part 3 and dividing it into 2 or 3 separate chapters. This would make the journey back to the light less overwhelming and more likely to be adopted.

The book has 2 “ends” – opening with a note of contexting from the editor and an appreciative Foreword from a valued peer, Ron van Oers, Vice Director of World Heritage Institute of Training and Research in Asia and the Pacific (under the auspices of UNESCO), and closing with an Epilogue tabling the differences between Conventional Planning and Holistic Planning.

Part 1

Part 1 gives the history of Heritage Planning that arose out of Modernism in the 1800’s with many good intentions of those who sought to manage sites of value – but as the authors see in retrospect were very much influenced by the views and values of colonialism and the scientific empirical methodologies. Starting with the unexpected sinking of the Titanic as a major illustration of the shortcomings of these approaches (and the source of their iceberg metaphor), they note the problems that arose from inappropriate methodologies that has dogged the profession all the way to the 1960’s. One of the examples they repeatedly come back to is Yellowstone National Park – whose management is still addressing the impacts of early violations to natural heritage planning (e.g. removing predators) and recent incursions of humans into its borders (e.g. with snow mobiles).

McCool and Kohl explain the original intentions and many shortcomings of Rational Comprehensive Planning (RCP) and Technical Rationality (TR) and the many sites to which it has been applied around the world – generally with the same ineffective outcomes that result from top-down methodologies, applied with shallow to no attempts at participation and frequent disrespect to local cultures and life conditions. They offer many examples of “shipwrecked plans” from World Heritage sites and observe that if they are rampant under the management of that high-profile institution, they run rampant in many other protected places.

The authors go on to bemoan that the evidence of systemic failure in heritage management that has been denied, ignored, rarely analysed and infrequently researched. Therefore, the same RCP-style processes are being repeated around the globe, without clients or funders realizing they have a track record of failure around the world. The authors take a courageous stand in pointing out this as a grievous (if not unforgivable) oversight in their profession that wastes resources, negatively impacts cultures and intended beneficiaries but keeps the profession (and professionals) funded and in business.

The authors have designed a format to add value to their narrative by creating a scheme of commentary boxes:

- Tables & Figures – to convey data, relationships, information and statistics
- Outside the Box – to show how planning could operate differently
- Toolboxes – to offer tools for effective implementation (like Mind Mapping)
- Inside the Box – to show new approaches that are working in other environments
- Fire Box – tracking the four Learning Loops

Another daring structure that the authors provide that links all 3 parts of the book is their exploration of single, double, triple and quadruple loop learning. This emphasizes their proposition that managers need to be supported by learning at all 4 levels. Further, they recognize that this developmental approach to expanding management capacity may take many years – which few funders are committed to enable. This information is deeply explanatory (and why we dive to the bottom of the U) but also deeply disturbing as the authors are not in a position to offer a solution that can readily change planning cycles that seem to be locked into one- or two-year spans. However, at the end of Chapter 9, they get close to revealing the embedded pattern of relationships that could continue to hold this stuckness or if released into the holistic paradigm release them into holistic connections. With Table 9.3 they relate and compare the qualities of the three main actors in an intervention: Heritage Community, Technical Assistance, Donor.

The authors are skilled storytellers and generally respectful academics, documenting their points with relevant literature references that support their points. They quote all the right sources from other discourses making them available to this specialized one.

I am appreciative of the range of discourses that they tapped to support their arguments – from architecture (Schon and Argyris), to systems thinking (Kuhn, Meadows, Senge, Wheatley et al), to adult learning theory (Kegan & Lahey), leadership (Ackoff), city planning (Friedman and Jacobs), to biology (Jared Diamond), to their own professions as conservationists (Pedersen). They have also drawn effectively on the Integral literature starting with Wilber, but also embracing Hochachka, McIntosh, Martineau and Brown. They bring in powerful quotations from Maalouf and reference Centers for Human Emergence Netherlands and Global – but curiously omit to include in their References Spiral Dynamics' authors Beck and Cowan (SD) and references for Graves which are clearly implied in many aspects of their commentary (from Graves' quotation of "allowing people to be who they are"; to rewriting quotations from Maalouf by replacing SD descriptors with "Traditional", "Modern, "Post-Modern"; to their recognition of the importance of life conditions that underlie Graves and SD approaches such as their discussion of conformance and performance). Other authors that I am curious that they omitted from references are Esborn-Hargens (editor of the *Journal of Integral Theory and Practice* and co-author with Zimmerman of "Integral Ecology") – all contemporaneous with Brown whom they cite at length. These are academic niggles – but relevant to the credibility of this narrative.

The authors introduce a way to describe the worldview that is not working for heritage managers with the acronym PLUS (predictable, linear, understandable, stable). This then becomes contrasted with their proposition of a different mental model that captures the way the world really operates as DICE (dynamic, impossible to completely understand, complex, ever-changing). (The reviewer is curious why the authors did not choose the more commonly used VUCA acronym (volatile, uncertain, complex, ambiguous) which seems to capture the same qualities and thereby connect their approach to similar explorations in the discourse of other sectors?)

However, McCool and Kohl offer an incisive critique of a very widespread approach to strategic analysis, using SWOT (strengths, weaknesses, opportunities, threats). They critique the process as generally non-participatory, aimed at only short-term strategic elements with little or no consideration of emergence. Moreover, they go on to critique power dimensions and remind the reader of the contexts of power that the manager is subject to in making decisions, creating teams and implementing plans.

Even before we enter the Integral Chapters the authors make us aware that managers need to be well apprised of the importance of values because they not only impact the process of management but the outcomes of humans and non-humans (like elephants) in heritage sites. Likewise, they emphasize that learning for managers ought to be paramount, ubiquitous and continuous.

Before delving into the individual chapters focused on the Integral Quadrants, Chapter 4 offers a comprehensive and adept explanation of the key characteristics of the Integral Model including discussions of: states, stages, lines, types and quadrants. If the reader is already integrally informed, this chapter could be skipped – but for the novice to Integral discourse this chapter is invaluable and well illustrated with tables and examples. It finishes with a good explanation of Levels, drawing on Wilber, Brown and McIntosh to provide descriptions so that the manager can recognize themselves, peers, clients, funders and cultures. The chapter concludes that the "Integral Map Points Us Toward Possible Futures for Heritage Management" with the reassuring quotation from Ken Wilber that "if you study this Integral Map … it begins to make room …in your soul for all the parts of you that were disowned …[and] even makes room for those who did the disowning."

Part 2

With this encouragement, the authors then launch 4 chapters that provide a flotilla of integral lifeboats to explore a full AQAL approach to a holistic planning process.

In Chapter 5 they unabashedly support the criticality of "minding the mind"; the value of interior realities with a concise summary of "Forces that Influence Planning Implementation" from the perspective of first person "I". Without pulling punches they cover Perceptions, values and attitudes, Beliefs knowledge and expertise, Intentions and Cognitive Capacities. While doing this they leave the "hooks" in the table for the future chapters to cover the perspectives from "It, We and Its" – which should help the reader build on their understanding and insights of the evolving Integral Model. While showing the value of the mind-based psychological approach to planning (and how and why it is so often omitted), the authors also point to the barriers caused by its omission and the triteness of glossing over vision statements created with "glued together" concepts instead of taking the time to delve deeply into discovery through authentic participation. They do not give the benefit to the intervener of swift report production and rapid project completion because they have seen that when a plan is shifted to the responsibility of the intervener it will not be supported, owned or likely succeed. Such action punishes the target project twice – once through wasting financial resources that pay such an intervener and secondly with the loss of the many resources to the community who may suffer real loss from the intervention and achieve no gain.

In Chapter 6, the authors reach back to the lessons shared from Chapter 5, and point to strategies that integrate the "I" interior perspective to the "It" exterior perspective. They point out in Toolbox 6 strategies for making training stick – identifying the importance of the learning process (and not just content), self-directed learning, prior learning, integrating new learning with past understandings, and support networks.

The reviewer was struck by the "learning by doing" modelling outlined in the chapter – characterized by this statement "every meeting we have is a sample of the future that participants can expect to come”. The chapter values the role of skilled facilitation – but primarily the kind that leaves participants capable of managing their own plans and not becoming dependent on interveners, nor bogged down. The examples of One Sky and Hochachka’s experience in Nigeria offer enlivening models of practice that can be emulated. This chapter includes explorations of facilitation processes (that relate to Chapter 7 and could also have been discussed under the “We” banner) and allows the authors to point to the issues of power and capacity development in the hands of those who are mature versus those whose maturity makes them a danger to all.

This brings us to Chapter 7 where the topic is the Collective Mind or Culture and how they emerge from the ways we share values, ethics, visions, paradigms, mythology and legend. This chapter is full of stories that make the reader sit back and gasp (like the killing of the albino moose; how that impacted an indigenous tribe in Nova Scotia; and how difficult it is to make any restitution in such circumstances).

This chapter explores the collective methodologies that have become widely known under the “Art of Hosting” banner (not referenced by the authors – but described severally) with enthusiasm for their capacity to engage participants in meaningful ways. The authors do an excellent job in marrying the philosophical underpinnings of these approaches from collective consciousness/noosphere, to complexity science and Bohmian dialogue – showing why and how they can change the whole tenor of engagement. They also point to the impact the collective mind has on the management systems that can be built. They re-open the failings of TR and RCP and as they set out the kind of leadership, and structures of information needed, they open up into networks and communities of practice that bring the methodologies full circle back to the necessity of continuous and shared learning in community. They fire these ideas with fire itself, describing the clash of paradigms related to forest fires in natural heritage sites and the long battle to learn how Nature herself plans life in cycles. This is a very long chapter with examples coming from all 4 quadrants (on a meta level) that include Lean Practice in Manufacturing, Non-Violent Civil Disobedience, Military Debriefings and Research Networks. So, regardless of the reader’s background the examples ground the value of this quadrant in real-life practice.

The authors want to make this point decisive as the Lower Left quadrant has so often been omitted in traditional planning and RCP and TR. The chapter finishes with an appreciation of storytelling and by adding the third loop to the learning model – the one that revisions and modifies the vision.

In Chapter 8, we arrive at the final Lower Right Quadrant of Management Institutions that influence heritage sites. We look at Institutions, Policies and Technologies – set out in Table 8.1 in comparison with all the other 3 quadrants. The authors emphasize that this quadrant is generally the most familiar to the planning community because they tend to use the lenses of 3rd person science and organizations to design and intervene on heritage sites. Government agencies aka bureaucracies are critiqued for their generally Modernist operating principles (and/or Post-Modern shadows). They cite Brown’s research in reviewing eight books on sustainability to find the preponderance of Lower Right perspectives gave the narratives a very biased outlook. The authors call for innovation in this quadrant and offer strategies gleaned from the businesses who have created “safe spaces” away from the dominant gaze for innovation and experimentation. The authors argue for the value of the four “concurrent, interacting, fundamental perspectives.” The state that such a new model would not just be “interesting …[but] eminently practical.” They offer strategies for involving the Lower Right quadrant in balanced and interactive ways. An example is how they explore “Friends of Heritage Sites”. They suggest, “A friends group is an institutional arrangement (LR), informed by shared community values about heritage (LL), that increases a site’s capacity (UR), based on personal affinities and reinforces understanding and positive attitudes among visiting audiences (UL).” (p.217)

They take the time to explore whole new ways that plans can be formatted, suggesting they are a “means of arriving, not a destination”; that they should focus on commitments and not mere recommendations; recognize that they are collective works; that they should be offered in multiple modes from scenarios, to art, stories, videos; to non-scientific audiences (as well as scientists). Finally, they bring back their DICE acronym and herald plans that can be as flexible and imaginative as a DICE world demands. The issue of power is then re-engaged, and we are reminded that planning is about power – through decision making, agenda setting and shaping needs. But we are also pointed to the emerging power of networks that connect people, interests, plans and forces for change. They admit that their advocated approach to holistic planning redistributes power (and by doing so may create resistance amongst those who hold power before an intervention commences). But as an act of encouragement, Chapter 8 adds the fourth learning loop where the modification of core purpose and values enables a full cycle to be mapped (that, for example, in the case of forest fires is not just reconceiving policy but a whole life perspective (p. 234)).

This brings us to the last Chapter 9, and back into the light after surviving both left and right sides of the iceberg U-shaped journey. This chapter is both long and intense and would be better treated as Part 3 of the book and broken into several chapters. To get the most out of this chapter I would recommend reading it as if it were Part 3 in 2 or 3 chapters.

In their first section, they use a Kegan-Lahey table to summarize the journey from stating a goal, to identifying behaviours that counteract the goal and hidden commitments that compete with the goal. This helps them understand resistance to change and go on to identify shadows. And it sets the authors up to outline the principles of their Holistic Planning approach – one that transcends and includes both Modernism and Post-Modernism. Table 9.1 summarizes it as an AQAL Process with the 4 preceding chapters exploring the I, It, We, Its processes that care for stakeholders, trains people in their own wellbeing and health, facilitates dialogue and creates plans that recognize all 4 perspectives in institutions that operate systemically.

In the next section “Definition and Principles of Holistic Planning”, their exploration of *Holistic Planning is effectively Deep, Clear, Wide and High* (to cite Sean Esborn-Hargens). They admit it takes (significantly) more time than the older forms of planning but in taking the time up front, they contend that implementation will not only be possible but sustainable because consensus is achieved. Moreover, the authors recognize that not all leadership is the same (e.g. Traditional and Warrior styles) and each must fit the appropriate situation. This can enable traditional knowledge to complement scientific knowledge and open the door to everyone being a knowledge holder and everyone having the potential to learn. Even Technical Assistance can be recalibrated through the Integral model to support stakeholders in each quadrant to optimize performance. Borrowing from

Martineau's example that not everyone has to be integrally informed to be effective contributors, the chapter calls forth a Holistic Planning team that is:

- Multiperspectival
- Legitimate amongst constituents
- Enthusiastic and capable of implementing holistic solutions
- Include at least one champion of the protected area
- Transdisciplinary

Their guidance offers such teams detailed practices, reminiscent of Action Learning or Action Research cycles, focused on continuous learning that emerge communities of practice.

The last section of this chapter provides an Evaluation Framework by quadrant with the three main actors in an Intervention: Community, Technical Assistance, and Donor – each with a template for Indicator, Baseline and Progress. This provides a succinct method for adaptive learning.

This chapter claims the right to set out what the book has been working towards from the Introduction – namely a new way of Holistic Planning. It completes the case with Table 9.4, comparing Holistic Planning to Conventional Planning. These headings effectively summarize the whole approach and give the reader a satisfying grasp of the whole book. (This section might even be more effective if it formed the lead into Chapter 9 (or Part 3 of the book if it is re-published) because the reader receives a very clear picture of Holistic Planning as a result of the comparison.)

- Worldview
- Forms of knowing
- Dimensions of Reality
- Participants
- Power
- Planners Role
- Endgame
- Planning Frequency
- Community Involvement
- Metaphor for Planning
- Planning Investment
- Document Format.

Conclusion

Throughout *The Future Has Other Plans*, the authors seek not only to inform readers, but also inspire them by opening and closing each chapter with quotations from multicultural storytelling literature that entice and amplify the points they are making. The reviewer encountered many favourites but this example is the quintessence of what they have accomplished: "*If you want to build a ship, do not drum up people to collect wood and do not assign them tasks and work, but rather teach them to long for the endless immensity of the sea.*" (Antoine de Saint-Exupery)

The Future Has Other Plans definitely makes the reader long for Holistic Planning as the only sensible way to honour, care for and steward our valuable natural and cultural heritage. I recommend it to planners in all fields as a seminal reference for planning with an Integral Paradigm.

The Body as Vehicle for Transformation

Sonya Renee Taylor (2018) *The Body is Not an Apology: The Power of Radical Self-Love* (First Edition). Oakland, CA: Berrett-Koehler Publishers.

Reviewed by Shameeka Smalling[1]

The Body Is Not an Apology (TBINAA) is Sonya Renee Taylor's contribution to the world of transformation through the power of radical self-love. In this powerful work, she discusses body shame and its oppressive impact on our bodies while telling us that we can in fact reclaim our natural intelligence, what she calls radical self-love. The book is not about self-help but frames the chapters and sections with radical reflections and unapologetic inquiries that ask the reader questions meant to move them onto a trajectory from body shame and guilt, past self-acceptance, to radical self-love. The ultimate goal is global transformation; her framework embraces both individualism and societal relationships through an intersectional and systems lens.

The Body is Not an Apology was first a poem, then a global movement before being born into a book. Sonya Renee Taylor is a black, queer, feminist, poet, educator, thought leader, and Founder and Radical Executive Director of The Body is Not an Apology, a digital media and education company that focuses on radical self-love as the vehicle for social justice and global transformation. With over one million followers in 140 countries, TBINAA has a vast global audience, which means the book's audience is inclusive of all members of society. Taylor rejects the duality of academic work and self-help book, using inquiry to educate and, hopefully, help the reader to transform. It successfully illustrates how we, the readers, may have come to body shame and how it impacts us in society and provides the tools to change our thinking to that of radical self-love, reclaiming our natural intelligence and eventually transforming the world/finding liberation.

The Body is Not an Apology starts chapter one, Making Self Love Radical, by shaping the conversation around the ontology that we all have a body and articulates the intersectionality of the body. According to Taylor, all oppression is enacted through the body, therefore liberation from body shame and judgment begins with radical self-love. This is through the Three Peaces, peace with not understanding, with difference, and with your body. In chapter two, Shame, Guilt and Apology – Then and Now, she introduces us to the anatomy of body shame in ourselves and society through body shame origin stories, the Body-Shame Profit Complex (BSPC), and Body Terrorism. This discussion transitions to the crux of the book in chapter three, Building a Radical Self-Love Practice in an Age of Loathing, making peace with your body. Taylor explains that "living a radical self-love life is a process of de-indoctrination" (p. 59) and introduces a process of "thinking doing being". Taylor then describes the movement from individual to transformational radical self-love with the Four Pillars of Practice- taking out the toxic, mind matters, unapologetic

action, and collective compassion. In chapter four, A New Way Ordered by Love, TBINAA moves from the individual to societal impact. She discusses implicit bias through the analogy of speaking French, and circles back to in-group-out-group bias, which she introduces earlier in the book. Taylor states, “we must deconstruct body terrorism in ourselves and others to dismantle the systems and structures of body terrorism” (p.81). According to Taylor, this personal transformation will lead to world transformation. In the fifth and final chapter, Radical Self-Love Toolkit, Taylor houses the ten toolkit pieces under the four pillars of practice. Of note is that she uses these practical tools to teach us to love our bodies, and therefore others, more. Finally, Taylor acknowledges that for her, the answer to what liberation looks like is for every human to live in radical self-love.

Dozens of books exist about self-love; however, there are only two books on radical self-love: *The Body is Not an Apology: The Power of Radical Self-Love*, and *Radical Self-Love: A Guide to Loving Yourself and Living Your Dreams* (Darling, 2016). Gala Darling is widely known as the self-love guru and her book promises to be a tool for people to find their way to self-love. The book is designed to help the reader love themselves first and moves on to loving others, and then provides tools for self-love in the final chapter. The books do not focus only on the individual but delve into the complexity of relationships with others. *The Body in Not an Apology* is distinct in that the conversation is multidimensional; it is about dismantling body shame through radical self-love and using that radical self-love to love others enough to begin dismantling oppressive systems.

The book is self-described as “a global movement guided by love.” Taylor uses the body-shame origin stories to initiate the conversation about our relationship with difference. Through her definition and description of body terrorism the discussion of body-shame and the Body-Shame Profit Complex become much more significant. It demonstrates that society is one of laws that oppress bodies of all types through body terrorism. It gives an individual a lens into how loving themselves more can lead to being a contributor to a better society. The reader can expect to move toward radical self-love, and this will in turn lead to better treatment of others, which moves from the individual to the systemic lens of “a more just and compassionate world” (p. 56). Transitioning from body shame to radical self-love means looking at systems that oppress the body and disrupting them.

On the surface, *the Body is Not an Apology* is about body empowerment. But the book also addresses the fact that oppression is enacted and held within the body. This is relevant to the discourse Resmaa Menakem engages in *My Grandmother’s Hands: Racialized Trauma and the Pathway to Mending Our Hearts and Bodies* (Menakem, 2017). Like the trauma that Menakem says lives within black, white, and blue bodies, in her own way Taylor argues that oppression is a somatic experience. In recent years, the Black Lives Matter Movement, issues of police violence against black bodies, school shootings, all speak to terror that is lived and experienced within the body. TBINAA is a transformative read specifically because it defines and describes body terrorism for the reader. The urgency of violence in today’s society speaks to the need for this book now.

The Body is Not an Apology interested me because of my research on the concept of holding space. Multiple definitions exist for holding space. According to transnational Black feminist, Farah Tanis (n.d.):

> To hold space is to be present and contain the immediate and continuous energetic shift created when another breaks with silence. It is being there, present for another. It is to act as a stand, bear witness, create and sustain physical and emotional safety, and to nurture trust at the same time.

This definition, which comes from a transnational Black feminist perspective, speaks to the space that is held for healing. Another definition of holding space is "walking alongside another without judgment or attachment to the outcome. We don't try to fix or control we just are in the moment with them" (Plett, 2015). It is creating an energetic container for emergence, growth, development, expansion, healing, transcendence, and manifestation of ideas to occur. Holding space is a needed element in all healing. When we engage radical self-love, we are increasing our capacity to love others, which in turn increases our capacity to hold space. This can help create transformation in individuals and organizations, but to hold space for others we must first hold space for ourselves, and that begins with loving oneself. I looked for books on loving the self before, but they did not feel transformational to me. Reading about radical self-love in TBINAA, it hit me like an epiphany. I needed to re-evaluate my self-concept and how to engage my body. It brings me back to my work in holding space. As I answered the Unapologetic Inquiries and unpacked my body shame, it increased the capacity for holding space within my own body. This book, by working on an individual and systemic level, gave me tools for my research around holding space. It also brought me back to me something that was elusive, that "we know that the answer has always been love" (Taylor, 2018, p. xiii). TBINAA is a tool to use love within my own research and work and I believe this book will help any reader to do the same.

Lost in Rumi

Marman, D., Khalvati, F., Shafaei, M. (2019). *The Hidden Teachings of Rumi*. Ridgefield, WA: Spiritual Dialogues Project. Marman, D. (2010). *It Is What It Is. The Personal Discourses of Rumi*. Ridgefield, WA: Spiritual Dialogues Project.

Reviewed by Jonathan Reams[1]

As I was finishing writing my dissertation (Reams, 2002), I searched for an opening quote that could capture the essence of my admittedly fuzzy and even non-academic ambitions with that project. After considering a wide range of inspiring quotes from the leadership and or consciousness literature I was focused on in my dissertation and feeling dissatisfied, I turned to the poetry of Rumi and opened my dissertation with:

You knock at the door of reality,
shake your thought-wings, loosen
your shoulders,
and open
(Rumi, 1997, p. 200)

As I revisit this snippet of Rumi now 18 years later, I am struck by the layers of invitation the passage evokes. I aimed in my PhD to explore the subtler, transpersonal, transrational aspects of knowing and being and how to evoke them and impact our capacity for leadership. It was easy to get lost in this territory, as familiar markers, or even the concept of markers, or of concepts, all faded as the process of knocking at the door of reality, shaking loose of thoughts and stepping into the opening that emerged.

My attraction to the mystical, or transpersonal and such has been a thread throughout my life inquiry and writing. The idea of getting lost, or being in the cloud of unknowing (Wolters, 2018) and resting in a sense of the ineffable has always held an attraction. At the same time, a mental curiosity, a desire to know, (I appear to score as a 5 in the Enneagram), understand and explain things is also a driving energy in my life. Thus, my penchant for writing about things that are difficult to capture in words.

Over time, poets have been the ones to achieve this best, and while I certainly have no talent in this area, nor especially gone into reading much poetry, (I did dig into William Blake and other Romantic era poetry at one point in my undergrad studies), I do have an appreciation for how

poetry can open up these subtler spaces, evoking portals into the deeper realities of life. It is from this frame of reference that I have approached Marman's (along with his colleagues) work of creating an opening into the deeper works of Rumi.

In *the Hidden Teaching of Rumi*, Marman, along with his colleagues Khalvati and Shafei,[2] take the time to educate the reader into these hidden teachings, step by step initiating us into the layers of mystery Rumi reveals. The opening page sets the tone: "*I tell you a story that can't be spoken, and I hide it from observers when I say it*" (Marmon, et al., 2019, p. v). This is typical of Rumi's approach – to be speaking of what can't be spoken and hiding it in plain sight. This means there is a type of riddle, or koan presented to us that requires unlocking. This unlocking can come, I believe, through two main roads. One is that of experience, *adequatio* or having the personal experience(s) required to know what Rumi is pointing to.

The second is scaffolding, or bridge building and it is this approach that Marman and colleagues use. In the introduction they describe how Rumi is not asking us to just 'think outside the box' or watching how our beliefs limit us. They point to "lenses of perception" (Marman, 2015, 2018) that are deeply subconscious ways of seeing (I'm reminded of Bonnitta Roy's (2006) reference to the term 'view' instead of 'perspective' as a way of pointing to something deeper). This is a way of orienting us as readers, preparing us for the journey.

Each chapter begins with parallel text laying out one of Rumi's poems in Farsi and English. This is followed by commentary, sometimes general, sometimes unpacking the poem line by line. The opening commentary continues the theme described above.

> Reading Rumi's poetry is like chasing fleeting images that change before our eyes and flow from one to another. We become lost as we try to follow his twists and turns. This is exactly what Rumi is trying to teach us: How to lose ourselves as we follow something that is alive with beauty and love. (p. 39)

The flow of this commentary starts out carefully, guiding us slowly and surely into unlocking meaning hidden in the poem in focus. This brings us to a point where we can begin to see that Rumi is not merely spouting random, free association lines that have no clear connection to each other, as many of his interpreters have presented him. Each poem is a whole in itself. While the narrative source may jump from Rumi to his beloved teacher Shams of Tabriz, the meaning hangs together.

Marman and colleagues take the time in some chapters to bring up references to historical details that provide context and clues about specific incidents that Rumi is referring to. They also weave in references to Rumi's discourses (more on these later) that all provide more clues and weave the lens we can use to unlock the hidden meaning even further.

Then, as the book goes further, the commentaries shift gear. We no longer receive a line by line unpacking of the poems, but move into a set of commentaries that take us even deeper. In some ways, the poems focused on later in the book are more obtuse, the meaning requiring more connections to clues that need to be unpacked both from within the poem itself and from historical or other reference points. Yet the reward is even greater, and we come into view of a profound insight into an esoteric aspect of spiritual teaching.[3] No spoilers here, you'll need to read it for yourself to find the treasure.

---

[2] Farzad Khalvat and Mitra Shafaei both grew up reading Rumi's poems in Farsi and were able to contribute their firsthand native speaker's knowledge of the language, as well as the depths of their own experiences with Rumi's works, to the translation and commentary project.

Closely linked to this project, is Marman's earlier *It is What It Is. The Personal Discourses of Rumi*. This project was something Marman began in the late 1970s, going through layers of revision as he encountered new friends, colleagues who grew up with Rumi in Farsi and his own growth, all of which enabled deeper layers of meaning to be revealed. The over three decades journey shows itself in the quality of the translation as well as in the precision of the commentary.

Rumi's discourses are less known than his poetry. However, they provide an equal depth of invitation into the subtle realms. The chapters here follow a similar pattern, with a translation of the discourse into English and then some commentary. The proportions are different here, as the narrative form of the discourses provides easier access to much of the meaning.

All in all, there are 71 of these discourses. I took them as bedtime reading over a period of a few months, taking one at a time only on evenings when I felt receptive to the opportunity being presented. I have studied a number of discourses of this nature as part of my own spiritual practice and found these discourses, despite the 700 years of time and cultural distance separating me from them, to be highly impactful.

In many chapters, Rumi tells stories or parables that are as amusing to read as they are instructive. The layers of meaning are present in relation to the layers of being we listen with, as Marman says in his commentary: "Our human self hears and enjoys his stories, but he is also speaking to the deeper part of Self that recognizes there is nothing conventional or traditional in anything he says" (Marman, 2010, p. 138).

It is this "deeper part of Self" that likes to get lost. Lost from the mind and its limitations. Lost from the whims, push and pull of emotion. Lost from the biases that come with the human senses and consciousness. It is in this sense of losing the limitations of conventional forms of human perception that makes getting lost a worthy endeavor and opens us to the essence of our being. Getting lost in Rumi is an invitation to not only lose ourselves in his poetry, but to lose our selves entirely and fall into a vast ocean of being.

Jonathan Reams[1]

Welcome to this issue of Integral Review (IR)! We are pleased to welcome you to a new regular issue, which brings together a rich set of interesting articles, essays and reviews.

In the year since our last regular issue, we have gathered a diverse range of articles, essays and reviews that touch on a range of relevant and topical societal issues. This is just the kind of discourse Integral Review was designed to foster, so we are pleased to see this range of articles in the current issue.

In particular, we see the engagement of reviews related to topical issues in public policy broadly in relation health care (COVID-19 and interventions for psychiatric issues) that can inform further research and decision making. We also see the topic of relating moral development with business, which also has significant potential to influence thought and practice in these areas. We also have a look at the transformational power of action research inquiry methods that can inform not only formal research, but also personal practice.

From there, we have a rich discussion of JEDI (no, not Star Wars JEDI) issues from a developmental perspective – the discussion originating in a submission and continuing in an extensive response. We hope this stimulates more such rich discussion in this field and helps inform discourse in that timely public field that is much needed.

An update on work published in the last issue keeps us abreast of progress on an ambitious project worthy of the integral aims. Two essays bring personal insights into weaving together different domains and practices, and a transcript of a conference session from a decade ago offers a rich example of transcultural work. As well, as per usual, we close with a couple of extensive book reviews.

It has been my pleasure as always to be a small part of the process of this collection of works coming to the light of day. I would also note our ongoing commitment, taking at the beginning of our journey with Integral Review, to the open access process. We have undergone a thorough process of updating how we meet the criterion for being registered with the Directory of Open Access Journals, which has been rewarding to be listed there. As well, I recently was reminded that we are listed by EBSCO in the Social Sciences category, giving our authors' work broad accessibility. I have also noted the significant extent to which our publications show up in google scholar. All of this, on top of the continuing robust numbers of visits to our website and downloads of articles, keeps us grateful that this body of work is able to be available to our community.

---

Our peer reviewed section for this issue contains four articles. We begin with Oliver Robinson’s *COVID-19 Lockdown Policies: An Interdisciplinary Review*. This timely article takes a deep dive into four sets of research; biomedical, economic, psychological, and ethical. Each is addressed extensively, covering a wide range of complex analyses done in each field. Combining these and showing the importance of considerations in each domain for policy makers can help them make better informed decisions. As well, a postscript notes that the conclusions of this article are supported with a recent review of the cost-benefit analysis of lockdown measures.

Next, we have *A Relational Approach to Moral Development in Societies, Organizations and Individuals* from Michael F. Mascolo, Allison DiBianca Fasoli and David Greenway. This article brings together research in moral development and applies it to three cases in the field of business, using a relational based approach. The authors lay out the case for how relations between people continuously evolve a set of moral goods that then inform actions. This integration also includes how all of this arises in socially embedded contexts. This extensive elaboration of this perspective is then applied to the domain of business and how moral thinking is inherently integrated rather than separate. This is then illustrated through describing how three business cases integrate morality as an evolving relational process.

Then we have *A Systematic Review of HeartMath© Interventions to Improve Psychological Outcomes in Individuals with Psychiatric Conditions* from Lucy Field, Mark Forshaw and Helen Poole. This article examines research done using HeartMath tools, (see McCraty et al., 2009 in IR for an extensive background to the research behind these tools), with a very specific focus on how they have been able to contribute to addressing psychiatric conditions. The implications of this are significant, in terms taking a proactive, non-invasive approach that does not come with the same costs of traditional interventions, both for individuals and society. This systematic review can provide support and justification for further research in this area.

Our final peer reviewed article is from Hilary Bradbury and Lara Catone: *Cultivating Developmental Reflexivity: ART of Relational Inquiry Methodology for Self and Community Transformation*. This multi-layered article addresses multiple facets of our lives. It engages in the concept and process of inquiry, deepening our appreciation for the transformative depths that are possible. The core focus on action research transformations (ART) focuses this powerfully and elaborates the possibilities present. Two developmental case studies richly illustrate the power of this kind of inquiry. The article closes with a list of key points to consider in assessing quality in utilizing this method in research and in life.

We begin our editorially reviewed section of this issue with an engaging essay from Aftab Erfan, *The Many Faces of JEDI: A Developmental Exploration*. This article shines a developmental lens on the growing body of work on justice, equity, diversity and inclusion. Erfan outlines her own position and journey in relation to both sets of work before presenting a rich overview of how each stage of action logic approaches the JEDI issues. Her first-person narrative takes us inside the thinking and motivations of people at each stage and illustrates the developmental journey as it applies to these societal issues. Erfan closes with a set of implications for practice that illuminates the complexity of working with JEDI issues and gives names to aspects of people’s experience that can help move the discourse forward.

Efran's essay was circulated to various people to get feedback along the way and it stimulated a substantial *Response to Erfan* from Amiel Handelsman. Handelsman has been active on his own in relation to these issues (this knowledge is from personal correspondence with him over the past couple of years). His substantial response to Erfan's article elaborates six points about what makes her work important, adding important perspectives that enrich her article. He then goes beyond directly responding to Erfan and outlines his own view, and then contributes three aims that can enlarge the discourse in this field.

In our most recent regular issue (Vol. 16 No. 2, August 2020) we published *The Prometheus Leadership Commons: A Meta-Framework for Leadership and Leadership Development.* In this issue, Tom Bohinc follows this up with *A Promethean Mission – an Update on the Prometheus' Leadership Framework*. Bohinc describes the evolution of the framework to its current 2.0 status. The article begins by covering how various principles have been applied, tensions navigated, and processes engaged. It then describes the actual changes to the framework in version 2.0 how a variety of choices were made in this journey. There is then a section relating results from some focus groups that were run to examine how the framework might be applied for selecting early career leaders. The article closes with a list of future interests and open cautions.

We are pleased to present another essay from Marilyn Monk, *Psychosynthesis and the Alexander Technique*. This essay brings together her rich experience in both the Alexander Technique and Psychosynthesis. Coming from her practicing profession as a molecular biologist, in this essay she demonstrates other facets of her lived experience in the area of personal growth. Monk's own training in these methods allows her to show the complementarity of these approaches. Her descriptions integrate historical development of the two approaches with thorough reflects on their application in various life circumstances.

Huw Lloyd has contributed an introduction to some of his work with *Relations Between Cognitive Development and Spiritual Practice (Yoga)*. This essay introduces us to his particular constellation of perspectives on these two areas, integrating a wide range of conceptual frameworks. His conception of 'the active orientation' is central to how he weaves together personal experience with discourse on spiritual practices and aspects of cognitive psychology to illustrate what he sees as complementarity between these fields.

Back in 2013, we published a special issue on the Luxembourg Symposium Research Across Boundaries (link). An item that has remained unpublished from this event was a presentation from Enrique Dussel on *Transmodernity*. In this issue, I have dug up the transcription I made from a video recording from the event that I was able to access and made it as presentable as I could. It was a memorable presentation and gives a truly transcultural insight into the topic of transmodernity. I hope you enjoy it.

We complete this issue with two book reviews. One by Roland Slot and Sveinn Hrobjartsson on Marianne Bozesan's *Integral Investing: From Profit to Prosperity*. Bozesan's work in this area has garnered wide ranging attention for its depth and thoroughness in how she covers the topic and brings her knowledge of Wilber's integral approach and her personal experience to the topic. Slot and Hrobjartsson provide us an overview of the main text of the book and then provide us with three thoughts for further considerations.

The second review is by Heikki Jyväsjärvi on Eeva Kallio’s anthology *Development of adult thinking: Interdisciplinary perspectives on cognitive development and adult learning*. Jyväsjärvi gives us an extensive summary of the arguments Kallio makes for the need for this anthology. He then presents a summary of each of the book chapters, enabling us to have a good feel for the value of this rich presentation of thinking in the field.

Enjoy this issue!

COVID-19 Lockdown Policies: An Interdisciplinary Review

Dr Oliver C. Robinson[1]

Abstract: Lockdown interventions employed in response to the COVID-19 pandemic have been evaluated via research at biomedical, economic, psychological, and ethical levels of analysis. The aim of this article is to evaluate arguments from these four perspectives simultaneously within an interdisciplinary biopsychosocial review to help inform the political and scientific debate surrounding them. Biomedical evidence from the early months of the pandemic suggests that lockdowns were associated with a reduced viral reproductive rate, but that less restrictive measures also had a similar effect. Lockdowns are associated with reduced COVID-19 mortality in epidemiological modelling studies but not in studies based on empirical data from the COVID-19 pandemic. Psychological research supports the proposition that lockdowns may exacerbate stressors such as social isolation and unemployment that have been shown to be strong predictors of falling ill if exposed to a respiratory virus. Studies at the economic level of analysis points to the possibility that deaths associated with economic harms or underfunding of other health issues may outweigh the deaths that lockdowns save, and that the extremely high financial cost of lockdowns may have negative implications for overall population health in terms of diminished resources for treating other conditions. Research on ethics in relation to lockdowns points to the inevitability of value judgements in balancing different kinds of harms and benefits than lockdowns cause. Suggestions for future research are provided to promote an increasingly fine-grained and nuanced evaluation of these policies.

Keywords: COVID-19, ethics, government interventions, health policy, health psychology, interdisciplinary, lockdown.

Introduction

The COVID-19 pandemic has brought about a dilemma for governments across the world: whether to enforce lockdown interventions to reduce the spread of COVID-19, in the knowledge that such policies contain the potential for harms as well as benefits in managing the pandemic. The academic purpose of this paper is to present a multi-layered interdisciplinary analysis of lockdown measures, via a review of the biomedical, economic, psychological, and ethical arguments for and against them. The practical aim of the review is to act as a resource to help inform future decisions about whether lockdown measures are empirically and ethically justifiable given the complex and varied costs and benefits attached to them.

Lockdown measures are interventions enacted by governments in response to a pandemic that have all of the following three features (OECD, 2020): (a) A stay-at-home order and/or the requirement to not socialise with other households; (b) the forced temporary closure of businesses, schools and hospitality venues within a region, state or nation; and (c) legal statutes to ensure that violation of these restrictions is a criminal offence punishable by arrest, fine and in some countries such as India, up to two years in prison (Times of India, 2020).

Within these common parameters, lockdown interventions show considerable variety. They vary in duration, relation to the timeframe of a pandemic, severity of measures imposed, and penalties applied for not complying with measures. In terms of the variability in severity of measures, several governments have applied restrictive measures that have been called a lockdown in the media but do not qualify as one by the standard definition presented above. For example, Norway and Finland implemented restrictive measures early in the pandemic such as school closures, limits on the size of gatherings and guidance to work from home, but neither country implemented a stay-at-home order or restrictions on household mixing.

Lockdown measures are a 2020 innovation in pandemic response measures. They have no prior precedent apart from city-wide measures taken in the 1600s to manage plague outbreaks and a lockdown-type intervention involving the complete sealing off of Hoping hospital in Taiwan during the SARS outbreak (Cheung, 2020). The World Health Organisation (WHO) guidelines to handling pandemics published in 2019 does not refer to them. Business and school closures are mentioned in that document as measures of last resort, but there is no mention of stay-at-home orders or restrictions on household-mixing or gatherings (World Health Organisation, 2019). Similarly, lockdown measures are not mentioned in the UK Influenza Pandemic Preparedness Strategy (Department of Health, 2011).

Given the lack of precedent for lockdown policies in pandemic response literature, their mass adoption this year requires explaining. One reason is that China was the first to get the virus and the first to respond with lockdowns and the World Health Organisation then supported their approach, encouraging other countries to follow. China’s enforced mass quarantine response was in line with its authoritarian approach to governance (Ma, 2018). China enforced a stay-at-home order in the Wuhan province for two months, with punishments for those who disobeyed. The World Health Organisation then wrote a report in February 2020 in which it appraised these measures in broadly positive terms: “China’s uncompromising and rigorous use of non-pharmaceutical measures to contain transmission of the COVID-19 virus in multiple settings provides vital lessons for the global response.” (WHO, 2020, p.19)

The next country to experience a major outbreak of COVID-19 was Italy, and the government decided to copy China and implement a stay-at-home lockdown across its northern region. Soon after, Spain and Peru implemented lockdowns, then dozens of other countries followed within a matter of several weeks. Lockdowns had suddenly become the de-facto pandemic response strategy, as countries followed China’s lead (Whipple, 2020). Despite previous conclusions in pandemic science that keeping society functioning as normally as possible was the best way of maintaining population health during a pandemic (Inglesby et al., 2006), the world was launched into a social-political-scientific experiment that continued for the whole of 2020 and into 2021.[2]

There is an important difference between lockdowns used within countries employing ‘suppression strategies’ and those employing ‘elimination strategies’ in response to COVID-19 (Baker, Wilson & Blakely, 2020). Of the 180+ countries that have reported COVID-19 cases, as of January 2021, four are currently pursuing an elimination strategy. These are China, Taiwan, Australia and New Zealand. In these countries, the aim is to maintain cases of COVID-19 close to zero. The fundamentals of this approach are: (1) complete border closures to foreign nationals until herd immunity is achieved via vaccine, (2) strict quarantine for nationals returning from overseas, (3) highly developed test-and-trace systems, and (4) strict local lockdowns to contain outbreaks. In China, another mechanism at the centre of their elimination approach is mass surveillance via a governmental tracking app (Mozur, Zhong & Krolik, 2020; Zhouziang, 2020). It is expected that the borders of these four countries may remain closed until 2022, with possible exceptions of travel corridors between the countries (Mazzoni, 2020). An elimination strategy requires a number of features: (a) implementation early in the pandemic, (b) a highly developed public health system and IT infrastructure, (c) sufficient affluence to afford the absence of tourist and business travel for up to two years, (d) the capacity to totally close borders. In relation to this last point, three of the four countries are island nations with no land borders, and China, the exception to this, is using military force to maintain fully closed land borders.

The elimination strategy is not available as an option for emerging economies that have neither the infrastructure for such a policy nor the economic resilience to afford a full border closure for up to several years. It is also problematic for many wealthy countries for a variety of reasons. For European Union countries, closing themselves from the rest of the EU for several years is not viable given that the EU is premised on freedom of movement between member states. In the UK, closing the border between Northern Ireland and Ireland for a matter of years is not possible given the Good Friday Agreement. In the USA, states rather than the federal government set COVID-19 policy and there is no way of closing a state off from the rest of the USA. In sum, the elimination strategy remains an option for only a select number of countries.

The potential costs of the elimination approach will be known after the pandemic is over. For example, as of July 2021, much of Australia is currently having to go into another strict lockdown due to rising cases and its adherence to a zero COVID-19 ethos, while much of the rest of the world, including the USA and UK, is opening up. For a comprehensive review of the costs and benefits of it, see Baker, Wilson and Blakely (2020). Crucially, the elimination strategy requires local lockdowns to contain outbreaks. It cannot work without them. Suppression strategies, in which the virus circulates but government measures are taken to manage and slow it, do not inherently require lockdowns. Some countries and states that are employing suppression strategies have implemented lockdowns during the COVID-19 pandemic, but some have not. The review of the evidence presented below pertains to those countries and states employing suppression strategies.

---

[2] Inglesby et al. (2006, p.373) concluded “An overriding principle. Experience has shown that communities faced with epidemics or other adverse events respond best and with the least anxiety when the normal social functioning of the community is least disrupted. Strong political and public health leadership to provide reassurance and to ensure that needed medical care services are provided are critical elements. If either is seen to be less than optimal, a manageable epidemic could move toward catastrophe.”

Moral Reasoning and Complexity in the Context of COVID-19 Lockdowns

A moral dilemma is a decision-making scenario that has a range of possible outcomes that *all* lead to some amount of harm and/or distress. . The issue of lockdown as a pandemic response is an example of a moral dilemma; both enacting and not enacting the intervention leads to negative consequences for some. It is a particularly complex moral dilemma for several reasons. Firstly, the construct of lockdown itself is complex and multifaceted. A lockdown is in fact a composite of various non-pharmaceutical interventions (NPIs), which are combined by governments in different ways. Instead of seeing lockdown as an either-or matter, Altman (2020) argues that they can be conceived in more pluralistic and nuanced way. The range of policies classified together as lockdowns, and the different effects of short-term and long-term ones, means that simply being ‘for’ or ‘against’ will miss a range of intermediary positions. For example, many health professionals in the UK who supported the March-June lockdown did not support lockdown measures applied from September onwards. A good example of this is an open letter from 77 primary care physicians to the British government written in September 2020, which argued that despite their support for the first lockdown, further lockdowns would cause more harm than benefit and so should be avoided (Haynes, 2020).

A popular but artificially simplistic portrayal in the media or in debate is of the lockdown advocate pitted against the lockdown sceptic (e.g. Melnick & Ioannidis, 2020). This is perhaps helpful for debate purposes, but it tends to drive an over-simplistic dualism in media arguments that the only alternative to lockdown measures is letting the virus ‘rip’ through a population uninhibited (Hamzelou, 2020). This is a complete misunderstanding of the range of non-pharmaceutical interventions available during a pandemic, most of which, unlike lockdowns, have a heritage of published research prior to 2020. Haug et al. (2020), whose work is discussed earlier in this article, list dozens of non-pharmaceutical interventions (NPIs) and their relative effectiveness that are not lockdowns, such as border restrictions, banning small gatherings or mass gatherings, quarantining cases, tracking and tracing, public transport restrictions, shielding vulnerable individuals, mask mandates and strategies for communicating information to the public.

A second source of complexity in the lockdown dilemma is the fact that effects of lockdown policies are varied in timing and duration, while spanning biomedical, economic, developmental and psychological outcomes. Altman (2020, p.31) argues that politicians have been focused on COVID-19 statistics to the detriment of considering other effects, due to employing “very narrow and simplistic mental models” and “poor heuristics” to direct policy. Effects of lockdowns include changes to the number of COVID-19 cases, hospitalisations and mortality, but also changing rates of other physical and mental illnesses, plus levels of unemployment, business closures, poverty, and child development. Some of these effects are immediate and short-lived, some are delayed and may last years. Balancing the varied costs of these outcomes requires value judgements, hence a purely objective approach to the dilemma is impossible. For example, what is worse, the death of an 82-year old or a 13-year old who develops a serious mental health problem that lasts for the rest of his life? The answer to that question is an ethical, not a scientific, matter.

As moral reasoning develops with age and experience, the complexity of moral dilemmas that can be meaningfully engaged with increases. At the heart of moral reasoning theory is how people respond to moral dilemmas (Robinson, 2020). The psychologist Lawrence Kohlberg (1981) theorised that there are predictable, sequential stages of moral reasoning that develop with age, which can be grouped into three main levels; *pre-conventional*, *conventional* and *post-conventional*. *Pre-conventional* moral reasoning (typical of young children) is founded on self-centred concerns about whether or not rewards or punishments will be received for a particular action. Here, the basis for morality is not within the self, but rather is an authority such as parents or teacher. *Conventional* moral reasoning (typical of adolescence onwards) is based on internalising societal conventions of what is right or wrong, and acting morally at this level is seen as integral to citizenship within a society. *Post-conventional* moral reasoning is based on principled reasoning about situations, based on a weighing-up of evidence and risk, while considering ethical principles such as honesty, wellbeing, liberty and justice. This capacity is typically developed in adulthood, but not all individuals reach a post-conventional level (Colby et al., 1983). This stage-based sequence of moral reasoning has been supported in a variety of studies (e.g. Armon & Dawson, 1997).

My aim with the interdisciplinary analysis presented below is to provide a post-conventional consideration of the dilemma of lockdown, which represents the full complexity of the issue, by looking at the problem from biomedical, economic, psychological and ethical levels. All these levels are important in informing a holistic and nuanced conclusion about whether lockdowns are efficacious and ethically acceptable. All these levels of analysis come to bear on a question that is ultimately moral in nature; can the harms caused by lockdown measures be justified by the extent to which they lessen illness and mortality?

The Biomedical Level of Analysis: Effects of Lockdowns on Cases and Mortality

Research on lockdowns at the biomedical level of analysis focuses on the relationship of governmental pandemic interventions to numbers of positive tests, case growth over time, and mortality. The principle argument for enacting lockdowns at this level of analysis is that they temporarily reduced hospital admissions and deaths, via reducing the transmission of viruses between individuals for the period over which the intervention is applied. There is a fast-growing body of evidence that can be used to evaluate whether lockdowns achieve this objective.

Studies that qualified for inclusion in this section on biomedical outcomes were published peer-reviewed articles from March 2020 to January 2021, via the databases MEDLINE and EBSCO Health Sciences database, via one of the following search terms “Government interventions, Distancing interventions, Lockdown” and one of the following search terms: “COVID-19, SARS-CoV-2, coronavirus”. Studies were included that contained empirical data on the association between NPIs and cases or NPIs and mortality, either as part of a natural experiment study or a modelling study.

Research Comparing Countries and States

One of the main methods that has been employed to ascertain if lockdowns are associated with reduced cases and deaths has been the comparison of mortality and cases across countries or states that have applied different levels of governmental response. The following country-comparison studies have studied case numbers in relation to government interventions including lockdowns, and the growing consensus is that lockdowns do reduce the case growth (termed the reproductive number or *R*), for COVID-19.

Haug et al. (2020) used data on interventions and cases in 226 countries up to 17th August 2020 to run an analysis of the relationship between different government interventions and growth in cases over time. It was found that the most effective method for reducing the rate of growth in cases was small gathering cancellation, followed by school closures and border restrictions. They found that lockdowns do reduce the rate of case growth, but they conclude that "a suitable combination (sequence and time of implementation) of a smaller package of such measures can substitute for a full lockdown in terms of effectiveness, while reducing adverse impacts on society, the economy, the humanitarian response system and the environment." (Haug et al., 2020, p.1309).

Li et al. (2020) studied data from 131 countries up to June 2020 and found that a decreasing case growth rate over a period of 28 days was associated with school closures, workplace closures, banning public events and a regulation to stay at home where possible. The study also found that while introducing restrictions generally led to a reduction in case growth of 3-24% after 28 days, lifting them led to increases of 11-25%.

Brauner et al. (2020) analysed effects of seven interventions (gatherings limited to 1000 people or less, gatherings limited to 100 people or less, gatherings limited to 10 people or less, some businesses closed, non-essential businesses closed, educational establishments closed, and stay-at-home orders) between 22nd of January and the 30th of May 2020, across 34 European countries and 7 non-European countries. They found that closing educational institutions, limiting gatherings to 10 people or less, and closing face-to-face businesses reduced transmission considerably. However, they found that the benefit of stay-at-home orders, which is the core of a lockdown intervention, was lower in effect than all six other interventions and they describe it as a small effect compared with the large or moderate effects of the other 6 interventions.

Bendavid et al. (2021) studied COVID-19 case growth over time in subnational regions of 10 Northern Hemisphere countries between February and April 2020: England, France, Germany, Iran, Italy, Netherlands, Spain, South Korea, Sweden and the US. They found that implementing non-pharmaceutical interventions was associated with significant reductions in case growth in 9 out of 10 study countries, including South Korea and Sweden (only Spain had a non-significant effect). The study found no benefit of restrictive lockdown interventions compared with the less restrictive interventions applied in Sweden and South Korea. In France, the application of lockdown was associated with higher levels of case growth rates compared with Sweden and South Korea. The study concludes that less restrictive measures generally lead to the same case growth rates as lockdowns.

Islam et al. (2020) looked at government interventions across 149 countries. All the countries in the analysis had implemented at least one physical distancing intervention (closures of schools, workplaces, and public transport, restrictions on mass gatherings and public events, and restrictions on movement (lockdowns)) between 1st January and 30th May 2020. They found that implementing measures without lockdowns led to a greater reduction in cases than those with a lockdown. Overall, they found that the implementation of all these measures reduced the incidence of COVID-19 by a modest 13%. There was a 4% difference in incidence between countries who implemented a lockdown earlier (14% reduction) compared with ones that implemented later (10% reduction).

In summary, the current research suggests that lockdowns do bring down case growth rates but no more so than more moderate and less restrictive interventions. Now I move onto summarising studies on lockdowns and mortality. Firstly, Chaudhry et al. (2020) compared COVID-19 case numbers and mortality data across 50 countries, based on data up to 1st May 2020. They also assessed these countries for the implementation of travel restrictions and containment measures including partial and full lockdown. They found that, in these early months of the pandemic, mortality rates were associated with higher obesity, higher GDP-per-capita, and higher income inequality, but there was no association found between mortality and the use of full lockdown measures.

Secondly, Bjørnskov (2021) investigated the association between severity of lockdown policies in 24 European countries in the first six months of 2020 and excess mortality (all-cause mortality, so not specific to COVID-19). No association between lockdown and mortality was found. Indeed, countries that applied a relatively severe lockdown experienced 372 excess deaths per million, while countries with relatively light restrictions only experienced excess mortality of 123 excess deaths per million.

Thirdly, De Larochelambert et al. (2020) in an analysis of 188 countries, using data up to August 31st 2020, found that high COVID-19 mortality was predicted by a country having higher life-expectancy, higher prevalence of chronic diseases such as cancer and heart disease, along with a high level of metabolic risk factors such as an inactive lifestyle and obesity. The stringency of government lockdown response was not associated with mortality.

Fourthly, Meo et al. (2020) compared lockdown measures across 27 randomly selected countries. Prevalence and mortality were measured 15 days before, 15 days during, and 15 days after the lockdown. There was no significant decline found in prevalence or mortality at the 15 day after measurement, when compared with 15 days before or 15 days during the lockdown.

Fifthly, Savaris et al. (2021) conducted an analysis of 87 regions of the world between February and August 2020, focusing on the relationship between deaths and stay-at-home orders. They used a time-series analysis to compare countries that had steady or declining death rates with similar countries were deaths were increasing. Google COVID-19 Community Mobility Reports were used an indicator of stay-at-home orders. They found “no evidence that the number of deaths/million is reduced by staying at home” (Savaris et al., 2021, p.8).

In contrast, one study by Sornette et al. (2020) that looked at 35 countries (European and North American) found an inverse association between the number of deaths during the 20 days following the date at which cases passed 1 per million within a country and the stringency of government measures 20 days before that date (to allow for the delay between infection and death). Almost all the countries on the intervention census date were still in the first half of March and so had not yet implemented a lockdown. For example, Italy, which had the earliest lockdown on March 9th, but this study looked at their interventions on March 2nd. Thus, this analysis is principally about the effect of interventions enacted *prior* to lockdowns.

The evidence from cross-country and cross-state comparison studies reviewed above is that lockdowns contribute to lowering the reproduction rate of the virus but that some other more moderate policies such as small gathering cancellation may be more effective than blanket lockdowns (Haug et al., 2020). Such evidence is further supported by within-country analyses that have looked at changes following interventions, such as Dehning et al.'s (2020) analysis of German interventions and found that banning small gatherings was particularly effective, and that a combination of interventions in April 2020 helped to reduce the *R* rate. The association between lockdowns and mortality shown by these cross-country and cross-state studies is very limited. The provisional conclusion is that there is no link between lockdown and mortality over the period of the pandemic that has elapsed to the end of 2020.

A caution with all the above research is that the studies are correlational, and there are a range of extraneous variables that can influence how a country or state fares in terms of case and mortality numbers, including population density, ethnic composition, COVID-19 testing capacity/methods, and the way that such data are reported. For example on the latter point, COVID-19 deaths are not defined in the same way across all countries (Sornette et al., 2020). Many of the studies described above do attempt to control for confounding variables, for example obesity and climate, but that does not preclude the possibility of others. Thus, the literature should, despite becoming increasingly consistent and clear, be treated with continued caution.

Computer Modelling Research

A different approach to analysing the effect of government interventions is via computer simulation of the no-intervention scenario. Flaxman et al. (2020) used this approach, looking at deaths attributable to COVID-19 across 11 European countries between February and early May. They modelled the combined effect of social distancing, self-isolation of infected individuals, banning of public events, school closure and stay-at-home orders, and so was not specific to lockdown. The researchers compared the actual mortality in these countries over February-May with a computer simulation of the scenario where no actions had been taken at all. Based on that, the article concluded that the interventions taken by these nations may have reduced COVID-19 deaths by 3 million.

Several commentaries have been critical of Flaxman's study. Soltesz et al. (2020) take issue with Flaxman et al. using their findings to argue that lockdown is effective, as according to the same modelling approach, the public events ban in Sweden was as effective as lockdowns in 10 other countries at driving down infection rates. Kuhbandner and Homburg (2020) in a commentary on the article presented evidence that the lockdown in the UK (one of the countries in Flaxman et al.'s study) had no effect on deaths at all, given the typical 23-day delay from infection to death. They show that growth was already declining by the time the lockdown would have influenced death rates and there was no shift at all in the downward trajectory of deaths when the lockdown would have potentially come into an effect. Wood (2021) reached the same conclusion in his analysis; infections were in decline before the implementation of lockdowns in the UK.

An epidemiological simulation study by Hsiang et al. (2020) modelled changes in case numbers over time between February and May 2020 across six countries (China, South Korea, Iran, Italy, France and USA) and concluded that, when compared with the computer scenario of no interventions taken, government containment interventions as a whole had reduced the growth rate of infections by a substantial and statistically significant amount. Their conclusion was that these public health policies had slowed the COVID-19 pandemic, and that, up to May, the number of cases and deaths had been reduced.

A limitation of all the aforementioned simulation studies is that they assume a continued exponential rise of virus cases means a doubling every two days in the absence of interventions indefinitely, but research has shown that virus case growth does not continue on a path of exponential growth; infection rates slow and decline of their own accord without any government intervention over a period of approximately 8 weeks (Ben-Israel, 2020). This hypothesis was put to the test when South Dakota had a high surge of COVID-19 infections in October 2020 and subsequently implemented no lockdown or business closures. The surge peaked in mid-October and cases returned close to normal seasonal levels in December, suggesting that 2 months is an appropriate estimate of the timeframe for a virus surge to decline without the use of restrictive interventions. This fact that there is natural remission from exponential growth without intervention means that Hsiang et al. (2020) computer simulations of the no policy scenario were likely overestimations.

In summary, the computer simulation research on combined government interventions has modelled the effect of all public health interventions versus a hypothetical scenario of no interventions taken at all and has concluded that the interventions have been instrumental in slowing the growth of the pandemic over the early months of February to May. What they don't show is the relative merits of lockdowns versus other measures. These models have also been based on parameters about virus growth, population susceptibility and lockdown effectiveness that have been questioned by critics. For example, Chin et al. (2021) describe these models as non-robust and highly sensitive to model specification and parameter selection. The models have also assumed that lowering infection rates also lowers deaths in proportion. However, the cross-country studies suggest that this assumption is unfounded. This may be because the varied collateral damages of lockdowns mean that while case numbers are lowered, susceptibility to serious illness and hence death is increased. I flesh out that claim over the course of the article.

The Biomedical Costs of Lockdown

A limitation with all the research studies discussed above is that they give no or minimal attention to the negative effects of lockdown in their evaluations of whether they work or not

(VanderWeele, 2020). This is equivalent to assessing the efficacy of a drug that has potentially deadly side-effects without any mention of the side-effects.

A key concern about lockdown policies, particularly stay-at-home policies, is that they lead to a decline in uptake of other important health services (Bodilsen et al., 2021). For example, lockdown in the UK led to a 70% decline in cancer referrals (Miles et al, 2020). The drop in cancer diagnosis and treatment has led some cancer specialists to suggest that a cancer pandemic may follow the COVID-19 pandemic (Hanna et al., 2020). An analysis of excess deaths in the UK from delay in cancer treatment during the March-June lockdown suggests that from breast cancer, lung cancer, colorectal cancer, and oesophageal cancer, over a period of 5 years following the pandemic there will be approximately 3300 to 3600 additional deaths. In light of the young age of many of these individuals, the total years lost to life from this cancer surge is calculated at approximately 59,000–63,000 (Maringe et al., 2020).

The challenge with interpreting reduced uptake of other health services during lockdowns is that the extent of such reduction in the event of no lockdown is unclear. People are likely to avoid hospital and medical appointments due to fear of a pandemic virus anyway, irrespective of lockdown injunctions. Future country comparison research on this will help to resolve this question, but until then the matter remains ambiguous.

A final issue in terms of negative effects of extended lockdowns on physical health is the drop in exercise and activity that is evidenced in a proportion of the population (Sport England, 2020). Exercise has been shown to enhance immunity to disease, so when a higher proportion of the population become inactive during lockdown, it is plausible that more individuals will become susceptible to illness when exposed to COVID-19 (Valenzuela et al. 2020).

The Economic Level of Analysis: Cost-benefit Calculations of the Effects of Lockdown

Financial resources for funding medical treatments and interventions are finite. Trade-offs must be made, as money used to fight one disease means funds being unavailable to treat or prevent others (Thomas & Stupples, 2006). A concept that is used by many countries to justify whether a treatment or intervention is worth the cost, in an environment of finite resources, is the “Quality adjusted year of life” or QALY (NICE, 2013; Bertram et al., 2016). One quality-adjusted life year (QALY) is one year of life in good health. Hence, when a young person dies, there is a greater loss of QALYs than when an older person dies. In the UK, the National Institute for Clinical Excellence has a metric to determine whether a treatment is cost-effective and thus should be adopted (i.e. that money is not better spent to save lives and alleviate suffering elsewhere). This metric is £20,000 to £30,000 per QALY saved (NICE, 2013). Other countries set the bar at different levels, but all health services require some kind of quantification in this regard.

Miles et al. (2020) conducted an economic analysis of the costs and benefits of the March-June 2020 lockdown in the UK. They analysed the potential lives saved by the March-June lockdown, on the premise that lockdowns do indeed save lives, then considered the costs of the lockdown in terms of reduced GDP. They found that in all their various calculations, the costs outweigh the benefits by at least £59 billion (2 million QALYs), and up to £547 billion (approx. 20 million QALYs). The authors concluded, “This suggests that the costs of continuing severe restrictions are so great relative to likely benefits in lives saved that a rapid easing in restrictions is now warranted” (Miles et al., 2020, p. 1).

One other cost-benefit analysis conducted by Israeli researchers found that a lockdown for 200 days would cost $45,000,000 per saved death, and as such governments should consider this very high economic price when deciding on how long to implement national lockdown interventions, given the inevitable toll on other public services and health services that are affected by reduced funds available (Shlomai et al., 2020).

A multi-faceted analysis of the economic and ethical implications of measures taken by governments conducted by Reddy (2020) expresses concerns that the expenditure and resources invested in lockdowns and other non-pharmaceutical interventions are not proportionate and will, overall, decrease the aggregate population health over time. For example, he makes the point that a 4.9% reduction in world GDP is predicted this year as a result of lockdowns, which is approximately US$4 trillion. If a world GPD growth of 2% is assumed as the counterfactual for 2020 (lower than recent years), then the cost of non-pharmaceutical interventions taken to combat COVID-19 would exceed US$5 trillion, which is greater than the total global annual expenditure on all other health issues prior to the crisis.

Reddy (2020) says serious questions must be raised whether lockdowns will, in fact, lower, rather than increase, overall population health over time, due to other health objectives that have lower cost and higher benefit being deprioritised. Consider the following figures as an example: The UK has spent £280 billion on fighting COVID-19, which is considerably higher than the total spending on health and social care in a typical year in the UK, while $2.6 trillion has been spent in response to COVID-19 in the USA. Meanwhile, the Gates Foundation has estimated that global eradication of malaria by the year 2040 would cost approximately $120 billion. Such an initiative would potentially save 11 million lives (Savulescu et al., 2020).

A further key issue at the economic level of analysis pertains to the number of individuals being pushed into poverty and/or unemployment during the pandemic. The World Bank has estimated that 150 million people may be pushed into extreme poverty during the pandemic (World Bank, 2020). The Charity UNICEF have explicitly linked this increase in poverty to the negative effects of lockdown policies (UNICEF, 2020), as have other researchers (Broadbent et al., 2020). There is a moderate correlation between GDP-per-capita and life expectancy (0.31 in developed countries, 0.47 in emerging/developing countries), and also between total health expenditure per capita and life expectancy (0.23 in developed countries and 0.51 in developing countries) (Biciunaite, 2014). Thus, we should expect to see a lowering of average life expectancy associated with the declining GDP due to the COVID-19 recessions across the world, and that this will hit emerging economies hardest.

Another form of economic cost-benefit analysis conducted by Thomas (2020a, 2020b and 2020c) has focused on the effect of lockdowns on decreased GDP and hence on mortality. This was established methodology based on a calculation called the J-value, which considers the trade-off between safety-increasing effects and loss of income due to the costs of implementation. The essence of this approach is to look at the change to *years of life expectancy* (which is very like the QALY concept) that a particular safety intervention brings. In relation to COVID-19 lockdowns, the cost is modelled as the effect on GDP. GDP is a very strong predictor of life expectancy; Thomas' J-value, based on GDP, explains 80 per cent of the variation in life expectancy across 162 nations (Thomas, 2020c). In other words, on average, the wealthier a country is, the longer its people live.

Thomas calculated that a 13% reduction in GDP for the UK was probable, along with an estimate based on previous recessions that the country does not return to pre-pandemic levels until 2022[3]. The increased impoverishment that this economic shrinkage causes will lead to the loss of 34.9 million years of life expectancy, which is the equivalent loss of 830,000 lives, given the life expectancy of the average UK citizen (Thomas, 2020). Even a scenario in which the pandemic is not controlled by any lockdown, the number of lives lost to the pandemic is a small fraction of the total lost to economic decline and increased poverty. Thomas thus concludes that lockdowns are remedies that may well have costs far worse than the pandemic (Thomas, 2020c).

A potential criticism of this cost-benefit approach is that GDP will be depressed in a pandemic anyway, so it is uncertain how much of GDP reduction is due to the lockdown. Sweden, with no lockdowns implemented, is a useful comparison in this regard; its economy is predicted to shrink by 2.9% during 2020, which is one of the lowest GDP declines in Europe despite mortality rates that are about average across European states (Reuters, 2020). Therefore, we have reasons to believe that lockdowns contribute to the majority of GDP losses.

Closely related to the issue of poverty is the increase in unemployment due to business closures and stay-at-home orders that have been implemented by countries around the world. For example, 400,000 more people in the UK were unemployed in December 2020 than in December 2019 (ONS, 2020). Approximately 5 million more people in the USA were unemployed in November 2020 than in February 2020 (Duffin, 2020), while more than 97,000 businesses had permanently shut across the US during the pandemic up to September 2020 (Sraders & Lambert, 2020). Unemployment is a high-risk factor for mortality. A meta-analysis of the relationship between unemployment and mortality found that the risk of death for unemployed persons was 63% higher than the risk of death for employed persons (Roelfs et al., 2011). While this can be partly explained by chronically ill individuals being more likely to be unemployed, another explanation for this link is that the stress of unemployment has been found to lead to markers of accelerated physical ageing at the genetic level (Ala-Mursala et al., 2013). A further concern is that unemployment rate has a close relationship with suicide rate; Canadian data shows that a 1% increase in unemployment leads to 1% increase in suicide (McIntyre & Lee, 2020), or as much as 2% (Samson & Sherry, 2020). Although suicide numbers overall are small compared with pandemic deaths, they tend to occur in younger adults and so equate to more quality-adjusted years of life (i.e. QALYs) lost.

There is evidence to support the proposition that economic problems driven by lockdowns are associated with mortality during the COVID-19 pandemic. Hasell (2020) has found a strong positive relationship between economic downturns caused by heavy lockdown measures and

---

[3] GPD UK loss from February to October 2020 was 8% according to the Office of National Statistics, thus 13% this is likely to be accurate when the November and January lockdowns are also factored in.

COVID-19 mortality. Peru is a case study in this regard. It implemented one of the toughest and earliest lockdowns in the world (Hannan, 2020). On March 16 2020, when there were only 28 confirmed cases, Peru closed its borders and imposed extreme limitations on freedom of movement. Public transport and cars were banned. Men and women were only allowed to leave their home on alternate days for essential purposes. The restrictions were enforced by the army. This cut down movement and mobility within the country by 89% - more than any other Latin American country (Jaramillo, 2020). Peru has remained in various levels of lockdown for much of the year since then. The effect on the economy of these measures has been stark; the percentage decline in GDP has been the highest of any country in the world, at over 30% (Hasell, 2020). Despite the severe lockdown, as of December 2020 Peru had the fifth worst fatality rate in the world out of 218 countries (Worldometer, 2020). Peru has similar demographics to its neighbours in South America and its health system has similar capacity, so this cannot account for its outlier status in terms of the high numbers of deaths. While there may be an as-yet-unexplained differentiating factor to explain its high mortality rate, one factor that makes Peru unusual relative to neighbouring countries is the extremity and duration of the lockdown measures it employed. Most people in Peru are in the informal economy and work in agriculture, mining and fishing. Most are paid in cash and have little or no savings (ILO, 2018), meaning that Peruvians need money weekly to feed their family. Therefore, for some it may have been a matter of stay in lockdown and starve, or break quarantine to feed your family (Piper, 2020). There is of course also little opportunity for working-from-home compared with developed countries that implemented similar lockdowns and there was no salary furlough scheme as there was in more affluent countries that enacted lockdowns. The sudden poverty, stress and malnutrition that this kind of extreme lockdown drives up in countries like Peru may drive up susceptibility to illness in ways that outweigh the benefits of reduced transmission of the virus. This would at least explain Peru’s contradiction between early and extreme lockdown and very high COVID-19 mortality.

One final consideration at the economic level of analysis is whether the approach to the pandemic taken this year is sustainable as an approach to pandemics going forward. If there were another pandemic in 5 years’ time, could countries afford to take this same approach again? Many countries will likely still be dealing with the effects of the post-COVID recession, the weight of their increased national debt, and the deleterious effects on social cohesion and mortality that high unemployment brings (World Bank, 2020). It is therefore doubtful that this year’s response represents an economically sustainable solution to global pandemics (Farsalinos et al., 2020; Gurdasani et al., 2020).

The Psychological Level of Analysis: The Desire for Paternalism vs Effects of Lockdowns on Loneliness, Anxiety and Behaviour

The psychological level of analysis considers the effects of lockdowns on thinking, emotion and behaviour, along with how these may have impacts on health outcomes. This level of understanding, so often omitted from media coverage, may be key to understanding the reasons why lockdowns do not have notable efficacy over more moderate or voluntary measures.

The first argument in favour of lockdown measures is that it may be what most people want, hence they have a democratic mandate. Polls in the UK showing high support for lockdown attest to this (Ibbetson, 2020; Smith, 2020). The psychologist Erich Fromm, in his famous book *Escape from Freedom* (1941), theorised that when people perceive an increase in disorder and danger within their community or environment, they feel an existential anxiety that breeds a desire for safety and security via paternalistic and authoritarian forms of governance. An example of this is seen in the actions and rising popularity of Markus Söder, Minister President of the German state of Bavaria. He intentionally implemented more draconian restrictions than other German states, such as a stay-at-home order (only one other state implemented this, while other states did not), and fines of up to €25,000 for non-compliance compared with no fines in some other states (Chae & Park, 2020). Söder was explicit about this approach being paternalistic – he said that "in a crisis, people often want Father to come and sort it out." (Rujevic, 2020). Söder's popularity increased exponentially as a result of his firm approach in the early months of the pandemic (Hockenos, 2020). However, the strict measures applied in Bavaria have not worked. They appear to have been less effective than the more moderate measures taken in other states; Bavaria has had the second highest COVID-19 mortality per capita of 16 German states, as of December 20th 2020. It has over double the mortality rate of seven of these states (Statista.com, 2020).

Another psychological argument presented to support lockdown is that lockdowns reduce the amount of post-traumatic stress disorder associated with bereavement and illness. For example, the UK government has justified its tiered system of mandatory enforcements by arguing that it is likely to lessen the burden from post-traumatic stress disorder, by limiting the number of those infected and who go on to suffer from severe illness (HM Government, 2020). The assumption here is that lockdown measures reduce symptomatic infection more than other non-pharmaceutical measures. The biomedical research reviewed earlier in the article does not provide clear support for this assumption currently.

Contrary to the claims of the UK government that lockdowns reduce anxiety, researchers have found that anxiety and depression both increase with the duration of lockdowns and that lockdowns are a serious threat to mental health (Fiorillo et al., 2020). Research in China also found that anxiety levels in a population go down when lockdowns are eased from 30% to 21% (Lu et al., 2020).

Another study using data from China in February and March found that depression was higher in the lockdown group but fear was not (Gan et al., 2020). In support of this, previous research on the effects of quarantines in prior pandemics suggest that they are related to depression (Brooks et al., 2020).

A recent review study by Cohen (2020) presents the compelling evidence from several decades of studies to show that psychological stress is a robust predictor of whether a person gets ill when exposed to a coronavirus or influenza virus, along with smoking and inadequate Vitamin C intake. The stressful events that were most predictive of coronavirus symptoms were interpersonal stressors and being unemployed. On the other hand, strong predictors of *not* getting ill when exposed to such viruses included social support and physical activity. Cohen concludes that lockdown interventions may *increase* susceptibility to COVID-19 due to their potential for stressors such as unemployment and social isolation, and the closing of environments where individuals retain physical fitness.

Loneliness and Lockdown

The effects of extended lockdown measures in 2020 on loneliness has been researched, and the most recent conclusion is that loneliness may itself be a silent epidemic running alongside the pandemic (Sharpe, 2021). A longitudinal study of 1545 US adlts found that from January to April 2020 there was no mean-level increase in loneliness (Luchetti et al., 2020). But as 2020 progressed, the statistics showed growing levels of loneliness. A more recent survey published in December 2020 found that 65% of US adults living under lockdown measures expressed high levels of loneliness, compared with 48% of those living without such restrictions (Killgore et al., 2020). A study from the UK found that loneliness rates in the UK increased from 10% before lockdown to 24% in lockdown (Mental Health Foundation, 2020). As of February 2021, the Office of National Statistics found that levels of loneliness had increased from Spring 2020, up to almost double the national average (Moss & England, 2021).

In the UK, some parts of the country have been under policies that ban almost all social interaction with people outside of one's own household for over four months in total since the start of the pandemic. Correspondingly, a recent report from the Office of National Statistics suggests that loneliness levels in the UK continued to rise all the way from March 2020 to November 2020 (Coughlan, 2020). A study that compared loneliness levels across Denmark, France, the Netherlands and the UK found that the UK's level of loneliness was significantly higher than the other three countries, particularly in individuals with previous chronic illness or mental health problems (Varga et al., 2021).

A major concern with high levels of loneliness during lockdowns is that there is an established body of research showing social isolation to be a very high-risk factor for mortality, comparable to the mortality risk of heavy smoking or obesity (NHS, 2015). A meta-analysis of studies found that social isolation, measured objectively or subjectively, increases the risk of premature death (Holt-Lunstad et al., 2015). After accounting for covariates, the increased risk of death was 26% for reported loneliness, 29% for social isolation, and 32% for living alone. Other studies have found that increasing the amount of social activity experienced by individuals in nursing homes predicts a decrease in mortality (e.g. Hjaltadóttir et al., 2011). One reason that loneliness leads to high mortality is that it brings about an endocrine stress response that impairs immune functioning and thus makes people more susceptible to disease (Cacioppo & Patrick, 2008). For example, one study found that loneliness is associated with poorer antibody responses to the flu virus (Pressman et al., 2005). Another study provided further explanation as to why loneliness affects immune function (Cole et al., 2020). They found that in isolated or lonely participants, leukocytes, white blood cells that are key to the immune system's response to infection, showed an increased expression of genes involved in inflammation and a decreased expression of genes involved in antiviral responses. Further effects of loneliness and social isolation are their impairment of restorative sleep, which leads to greater susceptibility to disease (Hawkley & Cacioppo, 2003). Furthermore, as with unemployment, loneliness brings about a higher risk of suicide, adding to the elevated mortality risk associated with the mass isolation that lockdown policies bring (McClelland et al., 2020).

A marker of those who develop severe symptoms of the COVID-19 disease is impaired immune functioning, specifically interferon deficiency in the blood (Hadjadj, 2020).[4] Given that loneliness and social isolation are recognised to be as dangerous as smoking when it comes to risk of premature death, extended lockdown policies that prohibit face-to-face social interaction over many months may increase mortality due to immunosuppressive effects, even if they alleviate some mortality via reduced transmission. Thus, what may appear as a COVID-19 death statistic may be partly precipitated by the effects of the social isolation that is inherent in lengthy lockdown interventions, particularly in older adults who are more likely to live alone (VanderWeele, 2020).

As well as impairing immune functioning, the loneliness and social isolation induced by lockdowns may influence behaviour after restrictions are lifted. The argument for this is that human connection is a fundamental need much like thirst or hunger (Cacioppo & Patrick, 2008), that the pent-up need for social contact after a lockdown will mean that many people may compensate for the weeks or months of isolation with a subsequent period of increased social activity (Spector, 2020b). This is what one finds with other unmet needs, for example, if someone is starved of food for days and then allowed to eat, they will gorge themselves as their brain seeks to compensate for the period of lack and scarcity, to bring nutrients back to required levels.

There is some research to suggest that people do indeed respond to the lifting of lockdowns by increasing the amount of social contact to an unusually high level, in ways that not only cancel out the benefits of lockdown but actually make the situation worse than before the lockdown. For example, an analysis of introducing and lifting restrictions across multiple countries found that introducing restrictions led to a reduction in case growth of 3-24% after 28 days, while lifting them led to increases of 11-25% (Li et al. 2020). In other words, after a temporary restriction of social activity is lifted, growth rates tend to increase to a higher level than they were before the lockdown.

More recently, Spector (2020a) has observed this rebound effect in the longitudinal data from the COVID Symptom Study, based on over 4.4 million British participants. He states that there is evidence of a rebound effect after severe short lockdowns, which may cancel out any temporary benefits. More anecdotal evidence from the UK is from media reports of unprecedented crowds in commercial environments directly after the lifting of the recent lockdown on December 2nd. One such report was of ‘mayhem’ as a ‘sea of people’ congregated outside of the Harrods department store on the first weekend after lockdown (Press Association, 2020).

There may be a deeper reason for irresponsible behaviour observed after lockdowns are lifted. Lockdowns work on the basis that a pre-conventional morality, based on the threat of punishment, must be used to enforce correct behaviour during a pandemic. Pre-conventional morality is what one applies to young children; moral guidance is dictated externally by parents, guardians or teachers, and is enforced through rewards and punishments. Young children’s behaviour is managed in this way because they have not developed an internalised ethic of civic responsibility, which is the foundation of conventional morality (Armon & Dawson, 1997). To apply a pre-conventional approach to managing the pandemic therefore means treating adults like children. The danger of such an approach is that by engendering a parent-child arrangement of external controls and punishments, lockdowns may actively undermine the tendency of people to behave like adults and to use their own good sense.[5] This has been discussed in relation to environmental ethical issues; Brisman and South (2015) argue that infantilization leads to irresponsible behaviour in relation to the environment. Evidence also suggests that the imposition of authoritarian policies can quickly reverse a sense of individual responsibility (Douglas Grant, 2019).

---

[4] Interferons are signaling proteins released by cells in response to the presence of viruses.

A topic that I have not covered systematically within this review is the effect of school closures on children's learning and social development. Many countries and states closed school for months during the COVID-19 pandemic, leading to a range of issues included slowed educational development, stunted social development, and mental health issues in children caused by isolation from their peers (Donnelly, 2021). The omission from this review is because the closure of schools is a pandemic response that may be used as part of a general lockdown or separate from a lockdown, and it has a recognised heritage of use prior to 2020. For a comprehensive review of the harms caused by school closures, the reader is directed to Ballan (2021).

The Ethical Level of Analysis: Evaluating Competing Ethics in Relation to Lockdowns

Scientific and public health advisors help to inform lockdown decision, but the value-neutral data and analyses of science can only be part of the matter when handling a complex moral dilemma such as a lockdown at a governmental level. Politicians must also navigate social, economic, psychological, moral and political trade-offs and competing concerns. Trade-off decisions inherently entail the consideration of values and principles as well as facts (Pardy, 2020). Ethics, as the study of such values and principles, must therefore play a part in selecting between competing policy options when considering government interventions for a pandemic (Patton, 2020).

Lockdowns lead to potential harms and benefits to a population, and this is at the crux of the ethical dilemma. The justification of harming some to help others stems from the moral philosophy of utilitarianism. Utilitarian reasoning is based on a consequentialist logic, which justifies an intervention or policy based on whether it leads to more lives saved than lives lost (Reddy, 2020). This is the *saving the greatest number* principle (Otsuka, 2006). Many who warn against lockdowns do so from the same utilitarian ethics, and suggest that lockdowns will likely lead to more death and suffering than they alleviate (Miles et al., 2020; Reddy, 2020).

Consider the following hypothetical scenario: You are a rescuer and there are two boats sinking; one has ten people in it and one has five people in it, but you can only rescue one boat

---

[5] A number of legal and political commentators have picked up on this in relation to COVID-19, for example Heffer (2020) wrote: "The Government has infantilized the country by denying people the right to choose what risks to take with their own health; it has taken to itself the duty of personal responsibility, which in a free and properly-run society must reside with the individual." Ridley (2020) has written similarly.

(Bradley, 2009). The utilitarian argument is that one should save the boat with ten people in it. Utilitarianism states that by saving the greater number from death, you will maximize the aggregate sum of welfare (Otsuka, 2006). Enacting a lockdown is a scaled-up version of this kind of dilemma; which proverbial boat – the boat containing people saved by lockdown, or the boat containing people that die as a result of lockdown – has more people in? Resolving this utilitarian puzzle requires very clear evidence on the effects of lockdowns on saving deaths and collateral deaths (Reddy, 2020).

Furthermore, given that those impacted negatively by lockdown, for example via unemployment or mental illness, tend to be younger than those impacted by COVID-19, should that matter? Generally, the utilitarian consensus is that the age of the people on the two sides of the dilemma should matter (Savalescu & Cameron, 2020). The concept of the QALY (quality-adjusted life year) discussed earlier in the article is an example of utilitarian reasoning that takes age into account. More QALYs are saved when the death of a child is avoided than when an elderly adult is saved from death, and that is then factored into the decision to employ a treatment (Reddy, 2020). So, the issue of relative age of those lost to COVID-19 and those who die due to lockdown collateral damage should be considered in the ethical debate.

While some broadly utilitarian cost-benefit analyses have been conducted on mortality caused by COVID-19 versus lockdowns, for example Thomas (2020a), substantive problems remain in using this information to inform political decisions from an ethical perspective, as the more intangible matter of *happiness* is also central to utilitarian moral reasoning. Utilitarian ethics is traditionally about maximising happiness for the greatest number (Stuart Mill, 1879). This of course means saving lives in a pandemic, but is not confined to that. Balancing happiness of the greatest number against saving lives requires subjective judgements of value. For example, the recent decision by many European governments to make social contact with other households at Christmas in 2020 a criminal offence, in order to help keep COVID-19 infection rates down and prevent hospitals from being exceeded in capacity, is an example of balancing happiness against saving lives. The standard ethical judgement for a normal year is that the joys of Christmas outweigh the dangers. Yet, every year across the Northern Hemisphere, hundreds of thousands of elderly adults die from influenza during January and February and hospitals are usually challenged by the numbers who are admitted with infection diseases in those months. Such illnesses will be partly contracted from social gatherings at Christmas. It is therefore likely that hundreds of thousands of lives would be extended if we banned Christmas every year. Critics of consequentialist moral reasoning argue that such deliberations cannot lead to meaningful conclusions (Shermer, 2018). The decision to allow people to gather in groups at Christmas in normal years, such critics say, is more aptly based on *deontological reasoning* about the right way to govern, rather than consequentialist calculations.

Deontological moral reasoning argues that certain kinds of actions are right or wrong no matter what their consequences (Waller, 2005). For example, considering the ethic of consent, consensual sex is right and non-consensual sex is wrong, no matter what the outcome. The philosopher Kant argued that honesty is an ethical principle that should be upheld no matter what the perceived consequences (Shermer, 2018). Critics of lockdown have based their concerns on the fact that lockdowns override the ethical principle of liberty. This ethic is founded on the premise that allowing mentally competent adults the freedom to choose between different actions, rather than being legally mandated or externally coerced to behave a certain way, supports flourishing societies and human dignity (Tucker, 2020). The principle manifests in a whole range of ways in liberal democracies: freedom of movement, freedom of speech, freedom of assembly, freedom of the press, freedom of religion, freedom of protest, and the freedom to refuse medical treatment (Beauchamp & Childress, 2008; Mandal et al., 2016).

The libertarian ethical argument against lockdowns states that allowing people to take responsibility for their lives and for each other, and so to make their own decisions based on clear information, elicits the best results in the long-term (Sumption, 2020). Most would agree that no-one would accept the kind of authoritarian policies that have been implemented in response to the COVID-19 pandemic on a permanent basis. Why not, *if* they would continue to save lives and drive mortality graphs downwards? Because it is human nature to value liberty and the freedom to live as we wish (Tucker, 2020). Some ethicists who combine libertarian and utilitarian arguments propose that quarantine or lockdown should be applied to the smallest number possible via targeted interventions, for example quarantining the elderly only, given the low risk that COVID-19 means to the under-60s. This is in itself a moral dilemma; I direct the reader to Savulescu & Cameron (2020) for an evaluation of it.

Applying the liberty ethic to public health matters such as lockdowns is based on three arguments that are worth making explicit with examples; (1) belief in the long-term benefits that liberty and autonomy bring despite the short-term risks, (2) the cultivation of trust between government and people and (3) that liberty is a way of ensuring positive community-mindedness. I will briefly review the these prior to considering the criticisms of lockdown from a libertarian perspective.

Firstly, the matter of accepting risk. Upholding the political principle of liberty, or the parallel principle of autonomy in medical ethics, means that individuals will take risks and may be harmed or die as a result of them (Beauchamp & Childress, 2008). Despite this, Western medicine and governance are founded on the premise that giving mentally competent adults autonomy in their decisions is worth that risk (O’Neill, 2002; Savulescu, 2017). Take drinking alcohol as an example: It leads to a considerable burden of illness – the World Health Organisation estimates 3 million people die every year around the world as a result of the harmful use of alcohol, which is greater than the COVID-19 death toll for 2020 (WHO, 2018). Despite the clear benefits to public health outcomes of banning alcohol, the decision is left up to the individual.

There is no doubt that legal prohibition of alcohol beverages brings lower numbers of alcohol-related illness, for example in Saudi Arabia where alcohol is banned, alcohol-related deaths are close to zero (World Health Rankings, 2018). And yet democratic societies continue to allow people to have the choice. This is part of a general commitment to the benefits of informed choice. In totalitarian societies, the general population may be safer in some ways, but the requirement to follow strict rules for day-to-day behaviour is known to stifle innovation, happiness and change. It creates stasis and fear while liberal policies allow for flourishing, experimentation and innovation (Kasparov & Halvorssen, 2017).

The second key rationale for the ethic of liberty is that it is central to cultivating *trust* between government and people, or between doctor and patient. When politicians and doctors uphold the right of a citizen to choose their own path, this conveys that they trust those individuals to take their own decisions, and to look after themselves and each other (Warren, 2017). Enforcing compulsory lockdowns via the threat of punishment conveys the message that people can't be trusted to behave well. While there is no doubt that some people would not act in a responsible or trustworthy way during a pandemic, a policy that assumes as much across a whole society is likely to be a self-fulfilling prophecy, for the reasons discussed earlier in the psychological analysis section: If you treat people like children, they will behave like children. Conversely, advisory policies that are based on informed consent, such as those used in Sweden and Japan, assume that people can be trusted. We could hypothesise, based on this, that in countries where authoritarian lockdown measures have been implemented, trust in government will have been eroded during 2020. This has indeed been found in a poll conducted in the UK in October 2020; trust in the British government has dropped to the lowest point in decades (Sugue, 2020). A recent peer-reviewed study has also found a drop in political trust in the UK during the pandemic (Davies et al., 2021). However, it is not clear how much of that is the pandemic response and how much of that is other matters such as Brexit. Future studies comparing trust in government across countries that implemented measures voluntarily or forcibly will be an important area of research in this regard. The potential effects of lockdown on the erosion of societal trust and on a decline in prosocial civic behaviour should not go overlooked.

The third argument for maintain the liberty of citizens in a pandemic is that it has a legacy of promoting positive community-mindedness. Philosophers who have promoted the societal benefits of liberty, such as John Stuart Mill (1860), have emphasised that giving individuals such responsibility and freedom allows for the cultivation of self-control, discipline, restraint, and community-mindedness. These can't be meaningfully cultivated in an environment of coercion and constraint. In support of this assertion that freedom of action actually enhances prosocial behaviour, a recent study found that voluntary social distance measures in the USA were more effective than enforced lockdowns in reducing mortality (Seegert, Yang, Gaulin & Looney, 2020). Another US-based study found that mandatory stay-at-home orders were ineffective because people were modifying their behaviour voluntarily before the mandates were put in place, again supporting the view that prosocial changes are taken volitionally in socially liberal countries (Berry et al., 2021).

Counterarguments to the libertarian critique of lockdowns point out that if a person with a virus is given the autonomy to behave as they want but then does so irresponsibly, they could put other people's lives and health at risk, and that this violates the libertarian ethic of doing what you want as long as it does not harm others (Compton, 2020). However, critics say that risk to others can be managed by more moderate laws and measures that do not require people to stay at home and businesses to close, but instead allow those who choose to congregate in a social environment to do so while mitigating the risk, such as via distancing and masks, much as they do when they drive to work every day or when they drink alcohol.

Another counterargument to the libertarian issue of trust is the argument that if a government failed to control a pandemic, this may lead to a greater loss of trust than that which is compromised by mandatory lockdowns (Spitale, 2020). Given that the current weight of evidence as it stands suggest that lockdowns do little to control the pandemic in terms of mortality, this counterargument is currently lacking in validity.

In conclusion, a number of ethical principles come to bear on the lockdown dilemma, and some of these are in dialectical tension. All modern liberal democracies combine liberty with some degree of paternalism (Wiley et al., 2013). For example, alcohol and cigarettes are allowed, but most countries ban other drugs. Freedom of speech is allowed, but defamation and slander laws put boundaries around this. Driving cars is allowed despite the high risk of harm, but seatbelts are legally obligated and driving when over the alcohol limit is banned. None of these standard legal restrictions remove civil liberties – they simply put some boundaries on relevant activities. Lockdown interventions, in contrast, temporarily remove some civil liberties completely. The matter of lockdown duration is key. If lockdown is for a short-time frame, for example a month or less, and is implemented at the start of a pandemic only to bide time to understand the disease and develop more targeted measures, this is less ethically problematic than keeping measures in place for many months. If another pandemic arrived soon, and lockdowns were again implemented in extended form, it would arguably start to set a problematic precedent. Ignoring the importance of liberty is, some argue, the slow path towards authoritarian governance (Kasparov & Halvorssen, 2017). Politicians and citizens alike must evaluate how much authoritarianism they consider to be acceptable in the name of saving lives during a pandemic (Wolff, 2020).

As a final point for ethical consideration, given the uncertainty in the current evidence-base for lockdowns, the medical ethic of *non-maleficence* is important to consider. It states that a medical practitioner has a duty to not cause pain or suffering (Beauchamp & Childress, 2008). Thus, in a situation where it is unclear if a new drug will harm more than it helps, the medical establishment would not approve it. If lockdown were therefore a drug, on ethical grounds we would *not* yet prescribe it, irrespective of the cost, until we have clearer information. However, a pandemic undoubtedly brings a range of ethical issues and challenges that are not pertinent to normal treatment approval, so whether or not this ethic is applicable to the lockdown dilemma is one that requires continued consideration.

Conclusions and Future Research Directions

The evidence base about lockdowns is still in a provisional state, as there was no precedent for these interventions prior to 2020. Currently, there is no way of saying with certainty whether lockdown damages will be greater than benefits or vice versa. Overall, the current evidence base leans towards harms outweighing benefits, but this may change if further evidence of a highly significant effect of lockdowns on mortality emerges with a longer timeframe of study across the pandemic that includes the second wave.

Based on the biomedical evidence as it stands at the time of writing, the provisional conclusion is that a combination of moderate measures, such as limiting gatherings to 10 people or less and social distancing, work as effectively as lockdowns to reduce growth in case numbers, without the damages inflicted by the latter. The stay-at-home order appears to be less efficacious than expected. Furthermore, currently, there is little substantive empirical evidence that lockdowns reduce mortality despite lowering case growth rates. This may be due to immunosuppressant economic and psychological stressors that increase the risk of death in ways that offset the reduced risk of mortality brought by temporarily lower infection rates (Cohen, 2020). This issue should be factored into the continued policy decision-making.

Economic harms of lockdowns have been calculated via modelling the effects of depressed GDP on potential loss of life years, and through calculating the effects on lost resourcing for health more generally. These studies, focused mainly on UK data, have mainly concluded that lockdowns will likely lead to more life lost than life saved.

From an ethical perspective, in addition to the utilitarian ethic of whether lockdowns increase or reduce suffering for the greater number, the matter of liberty must be included in the discussion, just as it has always been part of the discourse on ethics and epidemics (Ries, 2006). In countries that treat people as rational agents, capable of taking care of themselves and others, we know that medicine thrives, the economy thrives, education thrives, the arts thrive and society thrives, when compared with countries that do not allow comparable freedoms (Tucker, 2020). Overriding the liberal ethic of civic responsibility by mandating people to behave in a certain way through threat of punishment may get short-term results, but it may also set a paternalistic precedent of delegating power to authorities and away from the individual. In an international environment where there is already growing authoritarianism (Kasparov & Halvorssen, 2017), that path of social development is unpredictable. Yet there is nothing absolute about liberty; the matter of liberty set against legally mandated constraints is a trade-off balancing act in all areas of governance, and the COVID-19 pandemic is no exception.

All conclusions on lockdowns are provisional given that the literature on lockdown mortality effects will continue to develop across 2021 and there is little published research on the second wave of the virus yet. Furthermore, little is known about the effects of the timing, strictness, and duration of a lockdown. Short lockdowns will have fewer detrimental effects on unemployment and social isolation than longer ones, so the variable of duration must be considered in future studies that have access to data over a longer period of time than currently published studies.

In terms of future research, studies need to investigate how cases and deaths relate to: (a) the timing of the lockdown relative to the course of the pandemic, (b) the duration and severity of the lockdown measures, and (c) whether the lockdown is implemented in an emerging economy with high levels of absolute poverty, or a developed economy where there is a relatively high level of affluence and an employment market based around service and media industries where a large proportion of individuals can work from home. Importantly, the medium-term to long-term effects of lockdown policies must be examined as well as the short-term effects, considering the potential for rebound effects after lockdown, which are likely to be exacerbated by suppressed immunity from lockdown loneliness and inactivity that will likely extend to some degree past the ending of any restrictions.

The collateral damages caused by lockdowns should also be the focus of further study over the coming years. The issues include social isolation, unemployment and depression, poverty and its varied negative effects on health including impaired immune functioning, as well as depleted funds for other forms of healthcare, and issues that relate to communities and families that have been damaged: domestic violence, suicide, crime and more. Future research should aim to estimate how much more of these problems lockdowns bring compared with more moderate non-lockdown interventions, rather than just compared to a no-intervention scenario, and also how much the potential damage will differentially affect high income countries and middle-to-low income countries.

An evidence-based take on lockdowns is unlikely to reach a categorical conclusion that they do or do not work. A more likely conclusion, given the complexity of the dilemma, is that they may be beneficial at certain points in the pandemic, for example early in the process, but damaging if maintained as a policy over months or years, or that specific interventions within a lockdown may have an acceptable cost-benefit ratio while others do not. The current review has moved the debate forward by being the first to present four levels of analysis – medical, economic, psychological and ethical - that are essential for a full consideration of the pros and cons of lockdowns. The next step is to develop a conceptual integration of these four levels to provide a more unified rubric for political decision-making.

Important Postscript

This manuscript was completed in July 2021. At the time of going to press in December 2021, an up-to-date review of cost-benefit analyses of lockdown measures has just been published that broadly supports the conclusions of this review. It concludes that in all of the 11 cost-benefit analyses published, costs are shown to substantively outweigh benefits (Joffe & Redman, 2021). The authors conclude that lockdowns have “terrible cost-benefit trade-offs” (p.1) and that the continued COVID-19 pandemic response should recognise this and avoid them going forward.

A Relational Approach to Moral Development in Societies, Organizations and Individuals

Michael F. Mascolo,[1] Allison DiBianca Fasoli,[2] David Greenway[3]

Abstract: Discussions of morality in businesses and organization tend to center around the rights and freedoms of organizations and/or customers, or around the importance of socially responsible business practice. Rights-based deliberations are often invoked to justify the pursuit of self-interest, either by the business or customer. Calls for socially responsible practices function to constrain the self-interest of organizations, or otherwise prompt businesses to "give back" to the communities they serve. In either case, genuinely moral motives are often seen as secondary to what is assumed to be the primary goal of business – the pursuit of profit. We reject the common sense view that business and moral practice operate as separate spheres of activity. In so doing, we offer a relationalist conception of morality and moral development in everyday life. From a relationalist view, moral standards arise not from nature, God, the mind, or society. They emerge in embodied *relational activity* that occurs between people. Moral relationalism embraces neither moral universalism nor relativism, but instead views moral standards as a continuously emergent but constrained properties of discursive action that occurs between people as they negotiate and negotiate questions of "what ought to be" in physical and socio-cultural contexts. In this paper, we first show how the full range of moral standards arise in different forms of social relations between people. We then apply the moral relationalist framework to an analysis of the inescapable role of moral judgment in all business practices. In so doing, we suggest that business decision-making should be continuously informed by the tensions that arise between and among at least three moral frameworks: rights, virtue and care. We illustrate the moral relationalist approach to business through in-depth analyses of the moral mindsets of three entrepreneurs who integrate moral concerns into their business practices in different ways.

Keywords: Care, moral development, moral relationalism, rights, virtue.

---

[1] **Michael F. Mascolo**, Professor of Psychology, is Academic Director of the Compass Program at Merrimack College – an academic immersion program based on principles of moral self-cultivation. Most recently, he is co-editor (with Tom Bidell) of the *Handbook of Integrative Developmental Science* (Routledge). He is also the Director of *Creating Common Ground* (www.creatingcommonground.org), a non-profit devoted to helping people bridge divides on interpersonal, social and political issues.

Introduction

In what follows, we elaborate a relationalist approach to morality and moral development. From a relational perspective, moral values are neither universal properties of a fixed biological, social or spiritual world (O'Manique, 1990; Porter, 2014), nor are they relativistic constructions that are local to particular individuals, cultures, social groups, or historical epochs (Lukes, 2008). Instead, moral values, norms and frameworks are emergent products of *relations between people* that evolve historically within socio-cultural contexts; morality consists of fidelity to the demands of human relationships. Moral values and systems emerge as social agents identify, consolidate and promulgate *moral goods* that have their evaluative bases in human relational experience. From this view, morality is not simply something that arises in response to extraordinary life issues (e.g., life and death), but is instead a continuously emergent property of everyday social engagement. In what follows, we first elaborate upon the moral relational perspective. In so doing, we show how different moral categories emerge within different modes of relational activity between and among humans. We then elaborate the approach through analyses of how moral systems mediate social relations among adults in business and organizational contexts. In so doing, we describe how the moral relationalist framework provides a window into understanding how moral categories emerge and function in everyday life – and particularly in a domain of activity (business) often viewed as lacking a central moral dimension.

The Road to Relationalism

Despite the vast literature on moral development that has grown in the past fifty years, much of this work fails to consider the relational origins and development of morality. First, although moral life involves the rich interpenetration of judgment, emotions, experience, and values as they are organized within socio-cultural contexts, much of the literature has focused on moral reasoning and moral decisions – the cognitive aspects of morality (Kohlberg, 1969; Turiel, 2002). Second, much thinking on the nature of morality development tends to treat morality as a matter of extraordinary rather than ordinary life. In this regard, morality operates as a domain of functioning that is separate and distinct from everyday thinking, feeling and action. Third, moral principles and values are often seen as universal rules or standards that transcend time and place. Such a view runs the risk of viewing moral values as fixed and unchanging evaluative principles. From a moral relationalist view, moral values emerge through the very process of human relating over time. They are systems of strong evaluation (Taylor, 1989) that arise as humans seek answers to questions about the proper ways we should respond to the demands of social relationships (Donahue, 1977). If this so, the search for universal moral principles is likely to obscure the formation of an understanding the very process by which moral values are created. Below we examine these issues, and link them to specific research traditions in moral psychology. In so doing, we highlight problems in much existing theory that create a need for a theory of morality grounded in human relationships.

From Moral Cognition to Moral Integration

Much research in moral psychology addresses questions related to moral judgment or moral thinking. This focus traces to the cognitive-developmental tradition of Piaget (1932), Kohlberg (1969) and the suite of social domain theorists who have reacted to and built upon their work

(Nucci, 2014; Turiel, 2010, 2015, 2018; Smetana, Jambon & Ball, 2014). In his seminal *The Moral Judgment of the Child* (1932), Piaget focused on children's conceptions of the nature of morality. He produced evidence suggesting that the structure of children's moral thinking moves from heteronomous conception of morality (i.e., morality consists of fixed, external rules, handed down) to autonomous conception of morality (i.e., rules are seen as changeable subject to the mutual agreement of those involved in a given social encounter).

Kohlberg's (1981, 1984) constructivist model of moral development built on Piaget's insight that moral development could be understood in terms of structural changes in an individual's thinking about moral issues. Kohlberg argued that children initially confuse morality with authority and with social conventions and norms. Children move from incomplete and confused conceptions of morality to progressively more integrated and differentiated (and hence more mature) conceptions. These changes are reflected in the ways that children and adolescents justify and reason about their stances on moral dilemmas. Subsequent scholars challenged the claim that children's initial conceptions are mistaken and undifferentiated. Forming what would eventually be known as the Social Domain Approach, these scholars produced evidence demonstrating that children as young as 2 ½ could discriminate between moral violations and violations of social conventions (Turiel & Nucci, 1979). Nonetheless, the Social Domain theorists maintained a focus on moral reasoning.

This focus on moral thinking makes sense, as moral concerns are matters of evaluative judgment. However, thinking about moral life as primarily a matter moral judgment runs the risk of understanding moral life as something that is encapsulated within the cognitive sphere of functioning. As such, the focus on moral reasoning was noteworthy for what it left out of the study of moral functioning. In particular, traditional concerns about *moral character* (Hartshorne & May, 1928), *virtue* (Hamm, 1977) and *conscience* (Kochanska, Koenig, Kim & Yoon, 2010) were ignored and even disparaged (e.g., Kohlberg, 1981). The focus on moral reasoning raised difficult questions about the gap between moral thinking and moral action (Blasi, 1980). Still further, the study of moral development neglected the role of *emotion* in the organization of moral thinking and action – a process long viewed as central in the genesis of moral systems (Hume, 1751). In the past decades, these neglected issues have resurged as central aspects of moral development research (Miller, 2014; Nucci, 2018; Prinz, 2007; Svetlova, Nichols & Brownell, 2010; Tangney, 1987; Thompson, 2014; Walker, 2014). Developmental scholars have worked to develop increasingly integrative accounts of moral functioning and its development (Blasi, 2004; Cushman, Young & Green, 2010; Haidt & Kesebir, 2010; Kaplan 2017; Lapsley & Narvaez, 2005; Walker). Moral life is increasingly understood not merely as a matter of cognition, but in terms of the ways in which action is mediated by evaluative systems that arise at the *intersection* of bodily (Decety & Cowell, 2018; Liao, 2016), cognitive (Baird, 2018), motivational (Kaplan, 2017; Walker, 2014), emotional (Malti & Dys, 2015), experiential (Sherblom, 2015), linguistic (Tappan, 1997), identity-related (Stets & Carter, 2012) and socio-cultural (Ichiyanagi 2014; Miller, 2015) processes.

From Separable Domains to Socially Embedded Activity

Much of the cognitive-developmental tradition, reviewed above, aims to constitute morality as a distinct sphere of psychological functioning, in that the nature of moral evaluation is unique and hence qualitatively different from non-moral evaluations. In this way, morality can be fixed, defined by a set of features that is stable and constant, and would hold, for example, across cultures, contexts, and relationships. Nowhere is this aim more apparent than in the Social Domain Approach (Turiel, 2002). The Social Domain Approach proposes that there are different *domains* of social functioning – the moral, social conventional, and the personal (Smetana, Jambon, Ball, 2014) – distinguishable on the basis of unique formal criteria. The three domains differ formally, for example, on the source of legitimate regulation of actions. A distinctive feature of the moral domain is that it encompasses social actions that are perceived as "intrinsically" or "naturally" right or wrong. While these actions may be legitimately regulated by rules, laws, punishments, or social sanctions, the obligation to perform or to avoid performing such actions exists independently of these social regulations. By contrast, the social conventional domain includes social actions that are deemed obligatory precisely because they are regulated by rules, laws, or social norms. Social conventions include forms of address, uniforms, and other rules and norms designed to promote the smooth functioning and coordination of social groups and institutions. The personal domain encompasses social actions that are regulated by the individual actor, rather than intrinsically or socially (Nucci, 1981, p. 115; Nucci & Weber, 1995). These actions are taken to be up to individual discretion (Nucci & Smetana 1996, 2014).

For example, moral rules identify prescriptions against the theft of personal property. Social conventions identify more-or-less arbitrary agreements about where one typically stores one's personal possessions (e.g., clothing is typically placed in a dresser or closet; dishes in a kitchen cabinet). Beyond these spheres lies a personal sphere action of autonomy and personal choice. In one's own room, one is free to place one's dresser, desk, and lamp anywhere one pleases. From the standpoint of domain theory, these domains of thought have their own structure and, while they can overlap in any given act, develop in ways that are largely distinct from one another. Additionally, the use of these issues that we presented in order to exemplify and contrast each domain should be taken as only examples. The specific issues that comprise any given domain might vary (e.g., across cultures, contexts). It is the form of the domain that remains fixed, with its own internally complete and discrete structure.

Thus, according to the social domain approach, moral rules are those that are taken to be (a) *universalizable* in the sense that they are binding for people in other cultures; (b) *unalterable* in the sense that if there were no rule against the infraction it would still be wrong*;* (c) *non-contingent* in the sense that if an authority were to indicate that an infraction were acceptable it would still be wrong; and (d) *serious*, in the sense that someone engaging in the infraction would be subject to sanction even if the infraction did not violate existing conventional rules. Finally, moral rules are those that involve matters of justice, welfare, and rights.

In recent years, scholars have questioned the merits of the moral/conventional distinction (Kelly & Stich, 2007; Lourenço, 2014; Machery, 2012). They have argued and empirically demonstrated that the formal criteria do not always cohere in ways predicted by social domain theory (Shweder, Much, Mahapatra & Park, 1987; cf. Jensen, 2008). For example, some researchers (Kelly et al., 2007; Stich, Fessler & Kelly, 2009**)** have observed that participants across studies sometimes regard norms involving rights, justice and welfare as local rather than generalizable and as dependent upon authority. Additionally, beyond these conceptual and empirical questions, researchers have also suggested that there are social groups in which people do not make a moral/conventional distinction at all (Levine, Rottman, Davis, O'Neill, Stich & Machery, in press), and that the distinction is itself a product of a particular conception of morality and moral worldview (Shweder et al., 1987).

A related issue concerns the types of evaluative content that can be seen as definitive of a moral judgment. Haidt & Kesibir (2010) have described what they gave called the “great narrowing” of the concept of morality in Western psychology. In the past fifty or so years, psychologists have tended to limit the class of moral concerns to those organized around *rights*, *justice* and *welfare* (Kohlberg, 1980; Turiel, 2015). Such concerns, of course, are largely reflective of the individualist frameworks within which psychological scientists have typically operated. In recent years, this situation has begun to change. Psychologists have begun to expand their conceptions of morality. Psychologists have resurrected an interest in traditional categories of morality, which include issues related to virtue and character; the good and the worthy; compassion and care; in- and out-group loyalty; authority and duty; higher and lower; the sacred and divine; the pure and the polluted (Berniūnas, Dranseika & Sousa, 2016**;** Graham, Nosek, Haidt, Ier, Koleva & Ditto, 2013). While the debate over whether these concerns can be considered “truly moral” continues, we argue below why they should be, from a moral relationalist perspective. More broadly, below we outline our theory of moral relationalism, showing how moral concerns are not fixed but relative to relational experience, which in turn provides the grounding for a diverse and broad range of potential moral concerns. Before doing so, we trace the intellectual roots of moral relationalism.

Moral Relationalism

Moral relationalism holds that moral concerns emerge from and are legitimized in terms of the goods that arise from human relational experience. In this regard, perhaps paradoxically, moral relationalism harks back to Piaget’s (1928/1965) *relationalist* conception of human development. Piaget’s (1965) relationalist approach has its origins in the classic debate between individualist and holistic conceptions of sociological facts. The individualist approach maintains that society is merely an aggregate of individual persons. From this view, social knowledge is the result of the mere summation of the knowledge across individuals (i.e., “the whole is equal to the sum of its parts”). In contrast, Durkheim championed the holistic conception of emergent *sociologism*. From this view, social facts are irreducible wholes in the sense that they exhibit properties that do not exist in their base constituents (individual persons). Further, in his version of emergence, novel sociological wholes exist “exclusively in the very society itself” and thus are “external to individual consciousness” (p. xx, cited in Kitchener, 1991); they exist, for example, at the level of *collective* rather than individual consciousness.

Piaget rejected both extremes of the individualism-holism debate. For Piaget, social knowledge can neither be reduced to the activity of individual minds nor does it correspond to novel sociological wholes that operate somehow independent of their constituents (see Mascolo & Kallio, 2019). Instead, social knowledge (e.g., rationality, reason, social and moral norms) are products of relations between individuals. Piaget called this approach *sociological relativism* or *relationalism*. For Piaget, social wholes indeed show emergent properties, they do not form novel entities that are in some way independent of or “hover over” their parts. Instead, “social facts” arise from interactions (relations) between individuals which are consolidated into *rules*, *values* and shared *signs*. For Piaget, shared values have their origins in the personal desires (and values) of individual actors. When people interact, they exchange values, which then become consolidated into larger and more equilibrated systems of rules and meanings. In this way, the norm of reciprocity arises in social interaction as (a) the action of one person results in some (b) satisfaction of desire in another. As a result, a (c) debt or obligation to repay is incurred by the second person as a result of the action of her partner; this debt or obligation can be (d) repaid at some other time. The consolidation of the emergent meanings created by this pattern of interaction forms the basis of reciprocity norms.

Piaget's example of reciprocity illustrates the ways in which evaluative and moral concerns emerge from the structure of social relations. However, the example of reciprocity runs the risk of under-representing the full extent of the intersubjective nature of human interaction (Mascolo & Kallio, 2020). In the example of reciprocity, it is easy to think of interacting individuals as self-encased actors whose experiential worlds operate largely independent of one another. From this view, humans begin life as separate and independent individuals who become social only when they come into contact with other individuals. While novel forms of social knowledge may arise from relational activity, individual persons precede social relations. From a relational point of view, persons are relational rather than merely individual beings. Persons are both separate and connected, individual and social, distinct but nonetheless mutually-constituting (Gergen, 2009; Mascolo, 2013; Raeff, 2006, Shotter, 2017). Humans are not self-encased beings who come into the world cut off from the experience of others. Instead, humans enter the world with a primordial capacity for intersubjectivity – that is, an ability to share, coordinate and mutually incorporate experience between self and other (Di Paolo & De Jaegher, 2015). The development of a moral sense builds upon the primacy of intersubjective experience (Bråten & Trevarthen, 2007; Trevarthen, 1993) and the demands of relationships (Donahue, 1977).

This relational view of moral development is reflected in the seminal work of Emmanuel Levinas (1961/1987), a French philosophy of Lithuanian heritage who, as a Jew, spent time in concentration camp during World War II. Levinas' conception of moral action has its origins in his experiences in the Nazi death camps in World War II. The need to treat humans with moral dignity is often justified on the basis of appeals to a common sense of humanity. He noted that any attempt to include individuals under a common conception of humanity was limited by the nature of one's conception of the human itself. Levinas (1961/1987) warned against the dangers of *totalization* – the tendency to assimilate the Other to one's own conception of what it means to be human. Noting the ease with which some groups of people can be defined as other than human, Levinas turned this conception on its head. Instead of anchoring morality in a totalizing conception of humanity, Levinas grounds moral life in terms of ones' open-ended relation to the other – a spontaneous agent who is a continuous source of novelty. For Levinas, there is an infinity of meaning that lines behind and shines through "the face of the other" (Hendley, 2000; Waldenfels, 2002). My encounter with the other always brings forth the possibility of novel forms of meaning. The other is a constant source of potential novelty, always calling upon me to reconsider or revise my existing understandings of the world. I am thus never complete; the other always provides the possibility of novelty that calls for new forms of responsiveness from me to the other. I act as a moral agent each time I accept to the call to be responsive to the other and to the infinity that the other provides.

For Levinas, morality thus emerges from the very structure of relational life (Hendley, 2000). One's sense of responsibility to the other operates at a pre-reflective level within the very structure of interpersonal relating itself. In any social encounter, the other speaks to me and calls out a response from me. I am called upon not simply to respond to the other, but to be responsive to the plea of the other. It is in my very responsiveness that my responsibility toward the other emerges and evolves. It is my responsivity to the other that provides the grounding for ethical or moral life. Morality is defined in terms of the proper demands of being in relation to others. From a moral relationalist perspective, a moral framework is a *symbolic* system of *strong evaluation* that has its *origins in relations between people* and is *justified with reference to diverse goods that arise within intersubjective experience*. In what follows, we elaborate upon the meaning and implications of each element of this definition.

Symbolism and the Construction of "Nots," "Oughts" and "Ought Nots"

In his famous *Definition of Man* [sic], Kenneth Burke (1969) defines the human as a symbol-using animal. Symbols are representational vehicles through which persons can make one thing (e.g., a word, symbol, image) stand for something else (e., g., a meaning, object or sentiment.). The importance of this capacity cannot be overstated. According to Burke (1966), persons are not typically aware of "just how overwhelmingly much of what we mean by 'reality' has been built up for us through nothing but our symbol-systems" (p. 5). It is through the symbol that humans are able to extend awareness "beyond the information given" in direct sensorimotor experience (Bruner, 1972). We look and "see" a button affixed to a shirt. While the button appears on the retina in the shape of an ellipse, we are nonetheless aware that it is round. In this way, our representation of the object as a button bestows meaning beyond the registration of sensory patterns. Our knowledge of that which is "not there" structures our perception of present experience. Our expectations of what is typically "there" orients our attention to deviations from those expectations. For example, we might observe a person's shirt and notice the absence of a button. Our sense of the button's absence is noticed rather than seen, as we cannot see absence; we cannot see what is not there.

Humans live in the world of the negative. Our worlds are mediated by the *not there* whenever we notice a missing button; imagine what we will have for lunch; seek to live up to standards of worth defined by our communities, or long for a peaceful world. Of course, while we live in the world of the negative, "there are no negatives in nature" (Burke, 1969, p. 498). All that exists in the "natural world" is the *positive* – that which is *there*. Our sense of the negative is a produce of our capacity for symbolic representation. It is only a few short steps from the capacity to represent the *not there* to the capacity to represent what is *typically* "there" and, still further, to represent what *ought* to be there. When we enter the world of the "ought," we enter the world of moral judgment (Burke, 1966; de Waal, 2014; Tse, 2008). Moral judgments are judgments of what *ought* or *ought not* to be. It is but a few steps from the capacity to represent what is not present to the capacity to construct representations of what could be to the representation of shared standards for what should and should not be. The concept of *ought* implies the capacity to compare the *present* state and some absent, imagined or idealized state. To say, "Don't steal the cookies!" involves an act of comparing some possible state of affairs (e.g., Madge hitting her sister) to some representation of a more valued state – a state that is seen as right, good, worthy or otherwise valued (e.g., inhibiting the impulse to take what is wanted). When we act on the basis of what ought to be, we act within a word mediated by symbolically represented systems of right and wrong, good and bad, or worthy and unworthy.

Moral Judgment as Strong Evaluation

People are evaluating beings. Persons act on the basis of the evaluative significance of their circumstances. Moral judgments are forms of what Charles Taylor (1985, 1998) calls *strong evaluation*. Distinguishing between *strong* and *weak* forms of evaluation, Taylor (1989) defines weak evaluations are those directly involved in a person's pre-reflective wants, desires and interests. In contrast, strong evaluations emerge as people reflect upon the worth of one's wants, desires and interests. In weak evaluation, a person directly experiences the sweetness of the candy bar or the strain of physical exertion. In strong evaluation, one reflects upon the worthiness of sweets and exercise. Is it good that I eat so much candy? Is it good that I avoid the pain of exercise? Weak evaluations are direct and pre-reflective first-order evaluations. Strong evaluations are second-order reflections upon first-order evaluations. In strong evaluation, I reflect upon the *worthiness* of my first-order wants, desires, interests and actions. From this perspective, a *wanton* is an individual whose psychological processes are mediated by weak evaluation; a *person* is one who is able to make choices mediated by systems of strong evaluation.

The Relational Development of Moral Values and Frameworks

Drawing on these ideas, we elaborate upon five interconnected processes in the historical-relational construction of moral values in both societies and individuals.

1. First-order evaluations emerge within different forms of human relational experience. Social relations occur when at least two people come into contact with each other. Table 1 provides a description of the relational origins of different moral values as they arise with 10 basic forms of human relational engagement. For each of these 10 forms, Table 1 describes (a) the structure form of relating; (b) socio-moral questions raised by the form of social relating in question; (c) the basic modes of evaluative experience (i.e., "goods" and "harms") that emerge within each mode of relating, and (d) moral values, rules and emotions that that have their emergent basis in these various modes of relating. Moral values and systems arise as ways of resolving the problems that arise within different forms of relating. The forms of relating that motivate and constrain the construction of moral values are *emergent* processes. While some forms of relating are likely to arise in virtually all cultures and all times (e.g., *care* and *protection*), other forms of relating can arise only within particular social and cultural circumstances (e.g., concerns about *property rights* require the emergence of societies that raise questions about the control over land and resources).

Table 1. The Emergence of Moral Values in Diverse Forms of Relating

Relational Form	**Form of Social Interaction**	**Basic Experience of Good and Bad**	**Emergent Moral Values and Emotions**
1. Basic Verbal and Nonverbal Communication. How do I respond in communication?		Contingent responsivity vs. distress over non-responsive, non-contingent.	Responsiveness (Satisfaction vs. Frustration, Anger)
2. Boundaries vs. Intrusion. What is me/mine vs. you/yours?		Satisfaction of intimacy vs. pain, distress and anger over unwanted intrusion.	Respect for Boundaries and Personal Identity; Mine versus Yours; Ownership (Anger, Moral Outrage)
3. Acting and Restricting. What are the limits of my agency?		Freedom and joy of agency vs. pain, distress, anger and frustration of restriction.	Autonomy/Rights vs. Oppression (Anger, Moral Outrage)
4. Distributing Resources. How do we divide goods?		Satisfaction of want/ need in context of scarce resources; pain of inequity or lack of access to resource	Justice, Fairness, Equality, Merit (Anger, Envy, Jealousy, Pride)
5. Giving and Receiving. How do we respond to debt?		Satisfaction and joy of giving and receiving; pain of lacking goods, debt or failure of reciprocation.	Reciprocity, Duty/Obligation (Gratitude, Entitlement, Anger, Vengeance)
6. Responding to Need. How do I respond to your pain and need?		Empathic pain for the other; joy in advancing well-being of other	Morality of Care (Compassion, Empathy, Love, Sympathy)
7. Social Evaluation Relative to the Good. What is a “good” or “bad” person?		Pleasure in recognition of value of self; pain of social devaluation	Vice and Virtue; Good vs. Bad Character; Honor (Pride, Shame, Guilt, Embarrassment, Humiliation)
8. Group Decision Making. Who can make decisions in a group?		Satisfaction of order and beneficial leadership vs. distress of uncertainty and disorder	Authority, Hierarchy, Piety, Obedience vs. Subversion, Disobedience and Chaos (Fear, Respect, Security)
9. Group Integrity. How do we protect group integrity?		Safety and security of group belonging vs. fear and isolation	Group Loyalty vs. Betrayal; Group Identity (Loyalty, Patriotism, Affiliation vs. Fear, Shame)
10. Relating to the Divine. How do I relate to the cosmos?		Fear and awe in the order, power and beauty of the world; satisfaction of understanding, safety, certainty, guidance	Sanctity vs. Blasphemy

All forms of social relation are organized around some form of interpersonal *responsiveness*. There can be no social interaction unless social partners are responsive to each other's actions. Being responsive means more than simply responding to another person. Responsivity requires that social partners act with reference to the meaning of each other's actions and states. In development, perhaps the most basic form of responsivity consists of the relationship between the developing infant and a caregiver (Meltzoff & Brooks, 2007; Scholl 2013; Trevarthen, 1993). The infant comes into the world fully dependent upon the care of others. An infant who cries "calls out" some sort of response from her caregivers (Shotter, 2017). The infant's cries are immediately recognized as a signal of some form of need. The failure to meet the needs of the infant would bring about *harm* and *pain*; being responsive to those needs is thus *good* – not only for the infant but also the caregiver and the community at large. In this way, first-order goods and harms emerge in the very structure of infant-caregiver interaction.

2. First-order evaluations are intersubjectively identified, corroborated and verified within symbolic exchanges that occur between people. First-order goods and harms are experienced directly within the emergent flow of social relations. However, even though they are experienced directly, as pre-reflective aspects of experience, they are not necessarily *intelligible* to either self or other. The most obvious case of the unintelligibility of direct experience occurs in infancy. While young infants experience states such as hunger, fatigue and distress directly, they do not know that it is "hunger," "fatigue" or "distress" that are experiencing. While infants may be able to experience another person's expressions of care, anger or love, they are not necessarily aware that it is "care," "anger" or "love" that the other person is expressing. The capacity to make experience intelligible to both self and other develop over time through the capacity for intersubjective engagement with others (Bråten & Trevarthen, 2007). Within social interaction, infants and caregivers adjust their actions and experiences to the ongoing and anticipated actions of their social partners (Fogel, 1993). In so doing, infants and caregiver create and express novel forms of experience in relation to each other. In those interactions, caregivers use words to identify the experiences expressed by their infants, by other people and by caregivers themselves. Words are the repositories of already-existing meanings that have their origins in long histories of social relations. When a child learns to use the psychological lexicon of her community, she becomes able to represent experience – both her own and that of others – in socially sharable ways (Carpendale & Racine, 2011; Moore & Barresi, 2010; Vygotsky, 1978). As such, although children experience their psychological states directly, it is only through the use of language that they make those experiences into intelligible objects of shared social reflection (Cippolletti, Mascolo & Procter, in press; Martin, Sokol & Elfers 2008; Moore & Barresi, 2010).

It is thus through discursive interactions that first-order goods and harms are identified and made intelligible for objects of public reflection (McNamee, 2015). In infant-caregiver interaction, this occurs when a caregiver uses words to identify valenced aspects of an infant's experience-in-action. In everyday practical activity, when socialization agents use phrases like, "Are you *hungry*?" "Is it the teddy bear you *want*?" "Does that taste *yukky*?" "You don't *like* it when Daddy takes your bottle?" "Did that *hurt*?" "You *love* mommy," their words function as symbolic vehicles that parse the flow an infant's personal and relational experience (Carpendale & Racine, 2011; Rochat, 2015). In so doing, caregivers draw on culturally-shared symbolic meanings to provide the child with symbolic means for representing the goods and harms that emerge in everyday experience (Bråten & Trevarthen 2007; Carpendale & Racine, 2011; Moore, C., & Barresi, 2010).

Interpersonally, the capacity to use symbol systems to make relational experience intelligible provides caregivers with the means not only to identify goods and harms that exist in ongoing relational experience, it also allows parents and children to reflect upon and discuss goods and harms that are *not* currently present, but which *could*, *should* or should *not* exist (Martin, Sokol & Elfers 2008). At the social level of the community or society, the capacity to identify and reflect upon first-order goods and harms is necessary in order to identify second-order *moral* goods and harms – that is, shared strong evaluations of what should or should not exist in social relationships.

3. Moral values, rules and norms are intersubjectively created within symbolic exchanges in which people reflect upon first-order evaluations and coordinate them into shared, second-order strong evaluations. Moral evaluations are types of strong evaluation – second-order evaluations of first-order evaluative states (Rochat, 2015). Strong evaluations are reflections on first-order goods and harms. In a community, moral values, rules and norms emerge as cultural agents reflect upon, coordinate and consolidate representations of first-order goods and harms into shared (and contested) second-order representations of what *ought* and *ought not* to be (Tappan, 1997; Tomasello, 2011; Tse, 2008). The relationship between first- and second-order evaluations is neither obvious nor direct. First-order *goods* often come to be understood as second-order *harms* (Agonito, 1976). For example, while experiences such as sweetness and relaxation may function as first-order pleasures, we quickly become aware that too much of either can produce obesity. While physical pain and effort may be experienced as first-order pains, when they accompany physical exercise, pain and effort function as often experienced as second-order goods. It is in this sense that moral *character* can be understood as the cultivation of a proper attitude toward pleasure and pain (Aristotle, 1999; Cain, 2005; Wielenberg, 2002). If pleasure and pain consist of first-order evaluations, moral character emerges as the stable capacity to bring action into correspondence with second-order strong evaluations of first-order experiences.

Questions about the proper status of first-order goods and harms are ubiquitous. To the extent that different first-order goods and harms arise within different form of relational experience, questions about their proper status and roles in social life are ubiquitous. Each form of relational experience identified in Table 1 yields questions about the proper status and relations among different first-order goods and harms. Within any given form of relating, there are multiple possible answers to these questions. For example, social interactions naturally raise questions about boundaries and intrusion (relational form 2 in Table 1). It is likely that the differentiation of the physical body from its surrounds provides the experiential basis for higher-order conceptions of self and other. At a basic level, the boundaries of an individual person might be understood in terms of what can be considered within or outside of the skin. When a pinprick intrudes upon the skin, it causes pain – a first-order harm. The experience of such pains raises questions about the legitimacy of forms of intrusion on the self. While a pinprick may be seen to bring about first-order pain, the meaning of pain becomes transformed when the physical intrusion takes the form of a physician's needle. A strong evaluation such as "infants should be inoculated" arises as communities reflect upon, identify and seek to reconcile diverse goods and harms. Because it functions in the service of a larger good, the intrusion of the needle into the body takes precedence over the pain of the needle. However, this is but one way to resolve questions about the nature and legitimacy of boundaries between self and other. Circumcision is a practice the produces pain. How does the pain and removal of a body part comport with the cultural and spiritual meanings in which such acts are played out? There is no single answer to these questions. Instead, the moral status of these acts is established as communities seek to represent and reconcile diverse goods and harms in relation to each other.

4. Moral rules and values are legitimized (grounded) with reference to the first-order goods on which they are based and the extent to which they function to meet other higher-order moral goods. In the absence of any single standard against which to judge the moral correctness of a given action, it might be tempting to classify moral relationalism as a form of relativism. A common use of the concept of relativism states that, in the absence any objectively identifiable system of universal moral rules, moral values, rules and norms are relative in the sense that they are only valid under particular contextualized frameworks (Lukes, 2008; Slife & Richardson, 2011). Relativism is often justified on the basis of different moral or conceptual systems are based on qualitatively different presuppositions and thus are often incommensurable with each other. The validity of moral rules can thus be seen as relative to particular individuals, social groups or cultures as they function within particular times, places and social contexts. Moral relationalism rejects this view. While moral systems embraced by different individuals and cultures are often based on vastly different axiological foundations, relativistic views often fail to appreciate the diversity and conflict among moral values that exist within particular individuals, cultures and time periods (Wainryb, 2006; Wong, 2009). Neither cultures, individuals or time periods are monolithic structures (Hermans, 2001). The idea that moral beliefs are *relative to culture* implies a monolithic or homogeneous conception of culture. However, cultures are not singular unified entities. They are always organized with reference to multiple forms of both shared and contested values (Bhatia & Ram, 2001; Jensen, 2011; Wainryb, 2006). Moral values conflict both within and between cultures. As a result, cultures are not separate and discrete entities in relation to which moral values can be relative.

There is one sense, however, in which moral relationalism embraces a form of relativism. If moral values, rules and norms are relative, they are relative to *human relational experience*. Moral values and norms not only emerge within diverse forms of social relations, their legitimacy is grounded with reference to (a) the seriousness of those goods and harms, (b) the mutual constraints that emergent goods and harms place on each other, and (c) the extent to which such goods and harms lend themselves to intersubjective verification as good or bad. For example, perhaps the most salient moral good is the value of life itself. As a second-order moral good, the *sanctity of life* has its origins in a suite of embodied first-order experiences. These include experiences of the goodness of breathing, of maintaining bodily integrity, of satisfying bodily needs, of being free of pain and so forth. The fear of pain, of suffocation, of starvation and death are palpable ones. The value of life as a *moral good* arises from and is justified in terms of (a) the experiential seriousness and salience of these first-order goods and harms; (b) the ways in which patterns of these goods and harms – experiences like breathing, pain and the anticipation of death – cohere together and thus constrain the construction of representations of moral value, (c) and the extent to which the value of such experiences lend themselves to intersubjective corroboration between and among people. The capacity to corroborate experiences of the goodness of life, the harm of pain and the fear of death between provides the first-order foundation for the creating and justifying shared higher-order values such as the sanctity of life. The capacity to establish (and re-establish) intersubjectivity about the ubiquity and seriousness of such first-order goods and harms provides the foundation for the construction and justification of moral norms. To the extent experiences of good and harm can be intersubjectively corroborated as goods and harms, they are more likely to be generalized or universalized as moral norms – that is, norms that hold not just for me and you, but for increasingly encompassing groups of "us."

5. Moral systems develop in within and between both individuals and societies. Moral universalism maintains that a common framework of morality exists that has universal applicability across time and place. In refuting the existence of any form of universalizing standards, moral relativism maintains that moral values are relative to particular times, contexts and cultures. Both views are largely non-developmental. In understanding morality as an emergent product of lived relational experience, moral relationalism offers an alternative – namely that, moral systems themselves develop as humans grapple with enduring and emergent evaluative questions in real, developmental and historical time (Schinkel & Ruyter, 2017); moral progress (Hermann, 2019; Moody-Adams, 1999) is possible. Moral relationalism differs from relativism in the importance it places on the *other* in the dialectical development of moral systems. As expressed by Levinas (Waldenfels, 2002), encounters with the other offer the continuous possibility of novelty. Our engagements with others introduce us to novel ways of knowing, feeling, evaluating and being – ways that often *conflict* with or contradict those embraced by the self (Turiel, 2002). There are, of course, many ways to respond to the experience of relational conflict. One could close off the self from conflict, thus preserving the current integrity of self the while rejecting the contradiction of the other. Alternatively, one could give oneself over to the other, and act that would eliminate the conflict but destroy the integrity of the self. A third option is to approach conflict as an opportunity to resolve conflict dialectically – that is, to develop novel and more powerful shared beliefs through the integration of opposites.

Frimer and Walker's (2012) reconciliation model of moral developmental show how moral identities develop in individuals through the dialectical integration of opposites. As shown in the left panel of Figure 1, in their model, children enter the world capable of acting on both on the basis of *self-interest* and *concern for others*. Early in development, self-interest and concern for others develop along separate and largely independent lines. Self-interest is evident whenever a child seeks to satisfy personal need or desire; concern for others can identified in the empathic responses of young infants, and in the desire for older infants to assist other in the context of clearly expressed needs. Young children tend to exhibit self-interest and concern for others in different contexts. Over the course of development, the motives for self-interest and concern for others inevitably come into conflict. A child may want a toy for herself, but nonetheless notice (or have her attention called to) her playmate's distress upon not having access to the toy. In mid-childhood, children tend to have difficulty resolving such socio-affective conflicts. For Frimer and Walker, adolescence provides a choice point in the development of moral identity. During his period, adolescents seek novel ways to reconcile the conflict between self-interest and concern for others. In addressing this conflict, a developing individual may address the conflict by privileging self-interest over concern for others, or vice-versa. A genuinely moral identify develops when individual reconcile self-interest with concern for others. In so doing, they can begin to forge a moral identity around the idea that "it is in my self-interest to meet your needs" – or – at a perhaps higher level, "I will make the goal of meeting your needs part of that which defines my self-interest". While unmitigated self-interest is incompatible with care for the other, Frimer and Walker's model show how self-interest and concern for the other are transformed through the developmental integration of opposites.

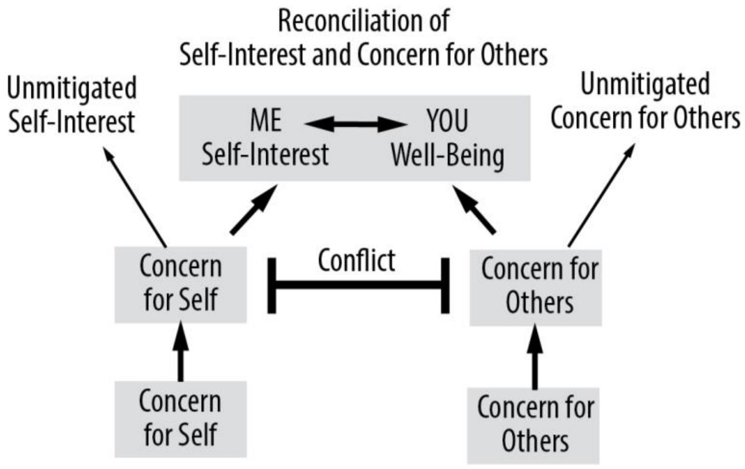

Figure 1: The Reconciliation Model of Moral Development

Frimer and Walker's (2012) reconciliation model illustrates several features of moral development. First, it shows how higher-order moral identifications develop through the constructive integration of *self-interest* and *care for the other*. In so doing, it shows how moral selves develop through relations that occur between people. Third, it shows how self-interest can be transformed through the process of relating to the other. The moral adult is not selfless. However, what it means to be a self becomes defined with reference to the moral demands of being in relation to others. Fourth, the model shows how different values – in this case, self-interest and concern for the other – become organized within a broader socio-moral system of beliefs over the course of development. A person's moral beliefs are not defined by any single moral orientation or domain, but instead by the dynamic coordination of multiple moral values in relation to each other. Each moral value constrains the other in the dynamic process of moral development. Still further, while Frimer and Walker's (2012) model was conceived with the development of individuals in mind, it is easily extended to understand the development of morality and moral beliefs beyond the individual. Moral beliefs develop as social agents – whether they be individuals or larger collectives – seek to adapt their actions and beliefs to the moral demands of relating to others. To the extent that individuals and groups are genuinely willing to *engage* rather than *dismiss* the concerns of the moral Other – it is possible to construct novel moral systems through the process of integrating opposing beliefs. Such a process would require the cultivation of a mutual willingness to identify "kernels of truth" in the opposing beliefs of the other. A relational approach holds out the hope that novel, higher-order and hybrid systems of shared moral belief can develop as people(s) seek to create novel forms of shared belief through the successive differentiation and integration of opposing systems of value. We have examined the dialectical construction of novel forms of individual and shared belief is discussed in several recent papers (Basseches & Mascolo, 2010; Mascolo, 2017, in press; Mascolo & DiBianca Fasoli, in press; and Marginean, LaTorre, Derien & Mascolo, 2019). The discussion now turns to an analysis of the ways in which adults construct moral frameworks for reconciling self-interest and concern for others in the context of a mode of interaction that is often seen to lack a moral dimension – owning or running a business.

Beyond Self-Interest: The Relational Construction of Morality in Business

If there is an arena that lends itself to an analysis of moral functioning in adulthood, it is the realm of business and economic life. The question of whether business and organizational activity can move beyond the monolithic and unquestioned principles of self-interest, individual rights, and the freedom of markets is hardly new. However, the search for a new social and economic framework that includes care for the other, society, and our natural resources has never been more relevant or urgent.

Evolutionary scholars have acknowledged that our species has flourished largely based upon our ability to collaborate and form communities for our mutual benefit and survival (Pirson, 2017). Indeed, organizations are "social structures created by individuals to support the collaborative pursuit of specified goals" (Scott & Davis, 2007, p. 11). But the modern day corporation is far from Smith's (1776) view of human beings as rational and self-interested but moderated by prudent evaluation. Friedman's (1970) assertion that profit is the singular purpose of corporations ignited an unbridled self-interest in contemporary economic life. The combustible combination of individualism – with a focus in economic gain, and market principles – within a culture that promotes growth without limits or harm (Boulding, 1966) brought on a half-century of shareholder primacy in the growth of business organizations.

A consequence of the growth, power and influence of organizations was the separation of the decision-makers and from those which are materially affected by the organizations (Beets, 2011). Before the mid-1800's, economic and social 'rules' were the province of individuals, families, or communities. With the advent of the industrial revolution, economic organizations grew to become the predominant canvas on which our ways of relating and being played out (Boulding, 1953; Stern & Barley, 1996). In the last half-century, however, membership in social, religious, and labor organizations has decreased sharply. It is against the backdrop of a 'go it alone' ethos of self-sufficiency that Putnam (2001) invoked metaphor of "bowling alone" to illuminate the collapse of community in contemporary American culture. This shift elevated the formal economic organization (i.e., corporations) as the dominate feature of our interpersonal relationships, our moral behavior, and in our relation to the natural world (Davis, 2006). However, these changes are far from a recent phenomenon, rather, they have "crept upon us silently. It is something we accept as natural almost without thinking. And yet, the whole movement raises problems with which we are ill equipped to deal" (Boulding, 1953, p. 4).

The 'winner' in this evolutionary race was the modern-day corporation, with "features that make it larger, more powerful, and more permanent than any individual human being" (Carroll, et.al. 2012, p. 11). Scott and Davis (2007) observe that even though these legal entities represent a small portion of the economic system in terms of number of entities, they have a disproportionate amount of social influence and economic power. This power is in part attributable to the corporation's rights as an artificial person which have continued to increase – rivaling those of the human person. Corporations as "artificial legal person" has enabled the accumulation of "previously unimaginable sums of money" (Carroll, et.al. 2012. p. 11). With this economic and legal power, Stoll (2005, p. 261) argued that corporate rights and free speech would "undermine the moral rationale and practical feasibility of guaranteeing rights of civil free speech to individuals." The imbalance of power and extended legal reach would likely lead to the "privatization of functions that have historically been the mandate of local, state, and federal governments" (Barley, 2007, p. 204).

A primary casualty of this imbalance of power is the what Becker & Ostrom (2003) refer to as the *Tragedy of the Commons*. The Commons, as proposed by Hardin (1968), *includes* ecological resources such as air, water, minerals, and other inputs into the economic systems that are available and equally entitled to all members of society. The Commons cannot be excluded nor can they be subtracted from the costs and impact of the organization's activity (Becker & Ostrom, 2003). For organizations, these resources are necessary means of production, however their extraction, usage, and disposal has far-reaching consequences on the environment as well as the dignity and well-being of the individual. The Commons have been disproportionately under the care and at the disposal of the largest economic entities.

How we care for and protect the Commons, as well as how we establish priorities and make decisions regarding social, economic, and natural resources extends beyond logic of free market principles. Market principles fail to live up to their promise when stakeholders are excluded from the evaluation of the exchange. The 1984 Union Carbide gas leak in Bhopal India is an example where the basic human right to safety was exchanged for a promise of future economic development (Jennings, 2012). Sandel (2012) speaks of the current tendency to view social problems as little more than a market inefficiency that can be solved with robust economic analysis and an appeal to the profit motive. He writes: "We have fallen in love with the idea of free market solutions to all manner of societal ills. And in doing so, it seems we have handed much of this judgment back to the markets, and by extension to corporations" (Sandell, 2012). He goes on to say: "The most fateful change that unfolded during the past three decades was not an increase in greed. It was the reach of markets, and of market values, into spheres of life traditionally governed by nonmarket norms" (Sandel, 2012).

Contemporary Movement Toward a Moral Marketplace

The ubiquity of these large formal and powerful organizations (corporations) has arguably improved the quality of life for large portions of the global population. However, economic inequality and the readily observable diminished living standards of much of the world's population stands in sharp contrast to record-breaking corporate profits and the increase in wealth of the top 1% of the populations (Adler, 2019). As the rights and influence of corporations have grown, the need for corresponding *responsibilities* has been brought into sharp review. As the rights of corporations have led to increasing power and influence, the need for corresponding *responsibilities* has been brought into sharp review.

The practice of *corporate social responsibility* (CSR) has emerged in part to counter the excess of corporate power and influence by shifting existing business practices toward more sustainable ways of working. However, as Adler (1999) points out, many CSR-related efforts serve only to reduce the rate and magnitude of harms to social and environmental resources but often fall short of wholly sustainable practices. Newer innovative business forms such as Benefit Corporations (BCorps) acknowledge the tensions between rights and responsibilities and are chartered with social and moral imperatives. BCorps fill a needed void by working to solve "society's most challenging problems cannot be solved by government and nonprofits alone" (*About B Corps | Certified B Corporation*, n.d.). These organizations eschew Friedman's profit imperative and are "obligated to pursue public benefit in addition to the responsibility to return profits to shareholders" (Hiller, 2013, p. 287). Noteworthy BCorps such as Patagonia, Greystone Bakery, and New Belgium Brewing operate in a sustainable manner both responding to and helping shape stakeholder values "toward more sustainable forms of consumption" (Painter et al., 2018, p. 88) and acknowledging the responsibilities borne by all stakeholders.

Moral Thinking in the Organization of Business

Business is often juxtaposed to morality. It is common to hear people contrast "from a business perspective…" with "from a moral perspective." From a moral relational approach, all human action takes place against the backdrop of inescapable moral frameworks. This includes business activity as well. To speak from "a business perspective" is not to adopt a non-moral stance; it is to act from the standpoint of "what is good for the business" – where "the business" refers typically to the survival and economic well-being of the organization. To invoke what is "good for a business is to adopt a moral stance – a stance that maintains that survival and the making of a profit is in some sense a good thing. The moment we do this, we have entered into a moral discussion. The moment we are aware that we are acting out of some form of self-interest (either at the level of the individual self or the business as a whole), there is no exit from the moral implications of our actions. While we may ignore the moral implications of our actions, they are nonetheless there. This is not to say that there are no moral justifications for acting on the basis of the interest of the business or the interest of the self. Would anyone suggest that individuals are not morally justified to act in ways that support their individual or group survival? There are thus justifications for acting in the interest of the self or business. However, if there are reasons that justify self-interest, there are also reasons that limit it and that direct us to attend to other moral implications of our actions in relation to others. It becomes necessary to understand self-interest as it functions within the broader context of human relationships. In business, as in life, we must act with fidelity to the proper demands of relationships (Donahue, 1977).

In what follows, we illustrate the ways in which business operations are and can be organized around moral values that extend far the principle of self-interest. In so doing, we describe the structure of moral thinking as by a series of business owners or managers in the context of open-ended interviews.[4] Three individuals are described here. The first is the owner and operator of successful dentist office in a small town in New England (USA). The second is senior chef employed by a major hotel in a major American city. The third is the owner of a marketing firm that represents select clients in major industries judged to make important contributions to the public good.[5] The two business owners are responsible for all aspects of the operation of their business; the chef is responsible for all local matters involving in the running of the hotel restaurant. This includes ordering food, setting prices, training, hiring and firing, and managing expenses.

---

[4] Interviews were conducted to identify and elaborate upon moral principles and values (see Table 1) that structured the ways in which owners and managers conducted their business. Sample questions used to guide the interviews are provided in Appendix A. These questions served merely as guides to initiate discussion which move in different directions depending upon the particular issues raised.

[5] Details about the particular businesses in question are omitted to protect the identity of the participants.

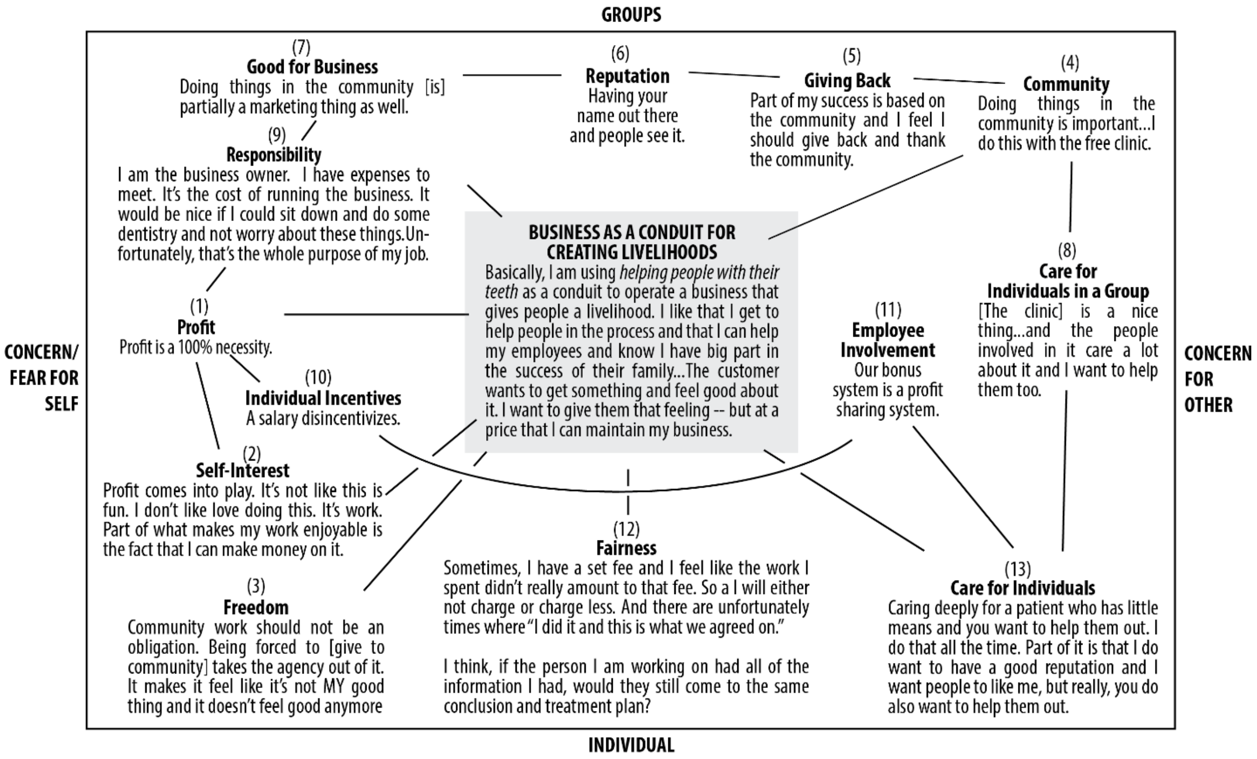
We analyzed the interviews by constructing interpretive themes suggested by the content of the interviewee's statements as they may or may not have related to the moral themes described in Table 1. We organized interpreted themes and verbatim statements into a two-dimensional socio-moral space. Drawing on MacMurray (1962), the horizontal dimension spans meanings from *fear/concern for the self* on the left and *concern for the other* on the right. The vertical dimension distinguishes between the extent to which statements refer to *groups* (top) or to *individual persons* (bottom). Each owner or managers' statements were organized within the resulting socio-moral space; relations among the various statements were identified wherever they could be grounded in the expressed content of their interview. Each socio-moral space displays the *structure of the moral thinking* that organizes the owner/manager's expressed approach to running the business.

The moral thinking expressed by each manager was both rich and variegated. The structure of each manager's thinking was organized around complex *relations* among *multiple moral values* that were tied to different *forms of relationships* involved in the running of the business. While the types of moral values expressed by the three managers revealed some similarities, they were organized around different moral principles. The dentist's moral thinking was organized around the idea of *business as instrument for sustaining livelihoods;* the chef's thinking was organized around the principle of *virtuous personhood and ethical exchange*; the marketing professional's thinking was organized around the idea of business as a *collaborative social project* rather than a means for making profit. In what follows, we describe the structure of each individual's thinking in more detail.

The Dentist: Business as a Means for Creating Livelihoods

> *I am using helping people with their teeth as a conduit to operate a business that gives people a livelihood. However, just because I take a fee for something doesn't mean I don't care for that person. The desire to help people with their health is a motivating force behind my business.*

At the center of the dentist's moral structure is the notion that his business, like any business, exists to "give people a livelihood." First and foremost, businesses help people by providing them with jobs. Jobs help families because they pay well and also because they initiate a relationship between employee and employer that is ongoing, where the employer is sensitive and responsive to individual employee needs. In this context, familial needs of employees can be met through additional exchange relationships. For example, paying for child-care for an employee also helps that employee return to work, which helps the business. As shown in Figure 2, the bottom line is maintaining the business so that it can continue to provide this kind of livelihood for its employees. Hence, (1) "profit is a 100% necessity" Ultimately, it is (9) the responsibility of the owners to ensure that there is a profit, so that the business can continue to achieve these ends. Profit is imagined not only in terms of the survival of the business as a means to livelihood. It is also imagined as a motivating force. Profit as motivating applies to each individual within the company. As a business owner, the dentist is motivated by profit (2) and for employees, bonus systems incentivize employees (11), while salaries – where the "profit" is fixed – disincentivizes employees (10).



GROUPS
(7) Good for Business
Doing things in the community [is] partially a marketing thing as well.
(6) Reputation
Having your name out there and people see it.
(5) Giving Back
Part of my success is based on the community and I feel I should give back and thank the community.
(4) Community
Doing things in the community is important...I do this with the free clinic.
(9) Responsibility
I am the business owner. I have expenses to meet. It's the cost of running the business. It would be nice if I could sit down and do some dentistry and not worry about these things. Unfortunately, that's the whole purpose of my job.
BUSINESS AS A CONDUIT FOR CREATING LIVELIHOODS
Basically, I am using helping people with their teeth as a conduit to operate a business that gives people a livelihood. I like that I get to help people in the process and that I can help my employees and know I have big part in the success of their family...The customer wants to get something and feel good about it. I want to give them that feeling -- but at a price that I can maintain my business.
(8) Care for Individuals in a Group
[The clinic] is a nice thing...and the people involved in it care a lot about it and I want to help them too.
(1) Profit
Profit is a 100% necessity.
(11) Employee Involvement
Our bonus system is a profit sharing system.
CONCERN/ FEAR FOR SELF
CONCERN FOR OTHER
(10) Individual Incentives
A salary disincentivizes.
(2) Self-Interest
Profit comes into play. It's not like this is fun. I don't like love doing this. It's work. Part of what makes my work enjoyable is the fact that I can make money on it.
(12) Fairness
Sometimes, I have a set fee and I feel like the work I spent didn't really amount to that fee. So a I will either not charge or charge less. And there are unfortunately times where "I did it and this is what we agreed on."
I think, if the person I am working on had all of the information I had, would they still come to the same conclusion and treatment plan?
(3) Freedom
Community work should not be an obligation. Being forced to [give to community] takes the agency out of it. It makes it feel like it's not MY good thing and it doesn't feel good anymore
(13) Care for Individuals
Caring deeply for a patient who has little means and you want to help them out. I do that all the time. Part of it is that I do want to have a good reputation and I want people to like me, but really, you do also want to help them out.
INDIVIDUAL

Figure 2: The Dentist: Business as Instrument for Livelihood

At the same time, profit is motivating not only on account of having additional money. Profit is also motivating, the dentist says, because it is an index of "how much I am helping people." He continues, "When I look at how much dentistry came through my office last year, I am not thinking, man I made a lot of money, but rather man we did a lot of work. That's a lot of people we helped." Profit is a concrete symbol of the care for customers (13). In this sense, care for customers is a central motivating force that is not "mutually exclusive" with profit. As the dentist urges, "just because I take a fee for something, doesn't mean I don't care for that person." Finally, profit indexes not only help for customers, but also help for employees. The dentist concludes this thought saying that profit means a successful business, which is one "that people really like working *for*." For the dentist, then, considerations of the business and care for individuals involved in and with the business are all wrapped into one.

Fairness is conceptualized as exchange that is freely entered into. When the dentist speaks of discounts, these discounts are not determined on the basis of the moral qualities of the customer's character, but rather on the qualities of the work that constitutes the exchange. When the amount of work – in terms of quality or quantity – does not represent the agreed-upon fee, the dentist will discount that fee, either "not charg[ing] or charg[ing] less." Prices are fair when they are willingly agreed upon and when they are proportional to the work conducted.

What underlies this conception is a deep notion of individual freedom that involves agency and personal choice. It comes into play when determining when and which customers to discount (12), it comes into play when determining whether and to which organizations to donate goods, services, and time (3), and it comes into play when determining when to give employees additional benefits. In all cases, there is a wide sphere where owners can decide how to relate to others in the context of their activities. This is perhaps most apparent when it comes to donating time and services to organizations and to individuals served by those organizations, such as the free clinic that the dentist is involved in each week. This involvement involves virtues that are tied to the business. These involve gratitude, in acknowledging the role of the community in the success of the business (5) and having a good reputation that will bring more people to the business (6 and 7). As such, these activities can be indirectly linked to the success of the business and to the livelihood it creates.

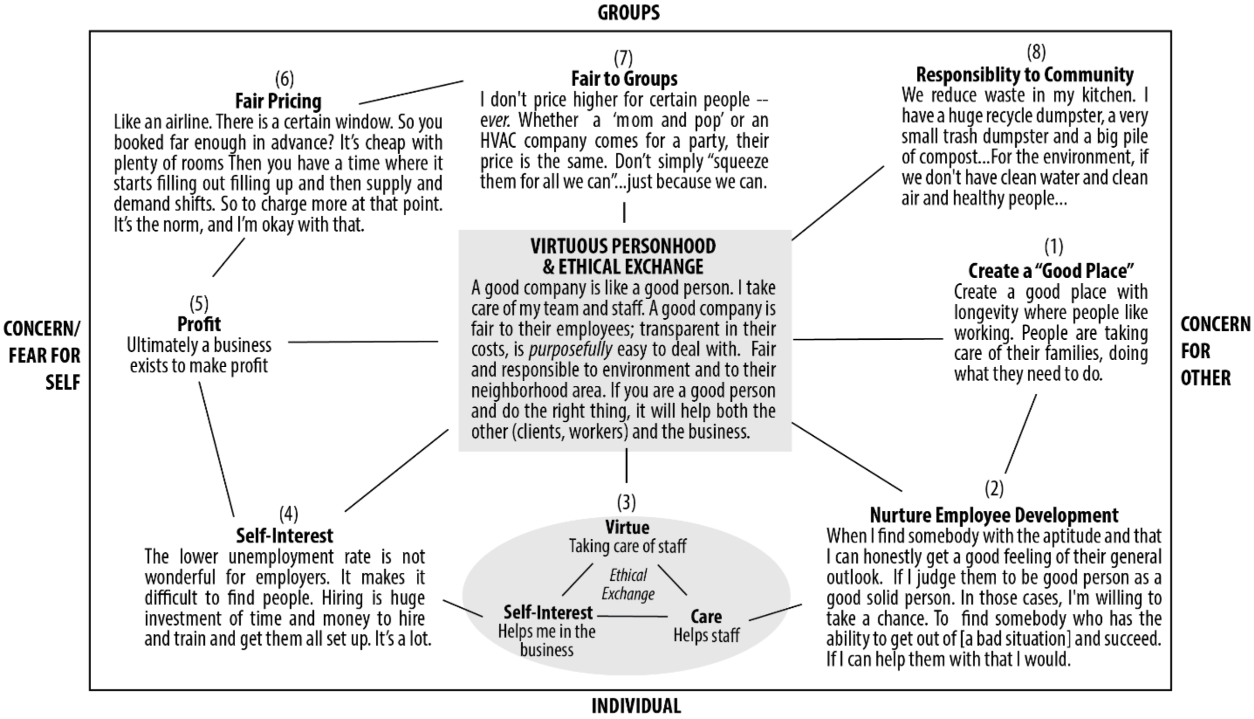
The Chef: Virtuous Personhood and Ethical Exchange

> *I would rather hire a good person who can learn how to cook than hire a good cook and try to teach him how to be a good person.*

In his interview, the chef described his approach to managing his kitchen around concerns for *care, virtue* and what might be called and ethos of *ethical exchange*. Throughout the discussion, the chef made repeated reference to the concept of "a good person" – that is, the need for the manager to act a good person, to hire "good people" – in the moral sense, and for the company itself to act as if it were a "good person." From the chef's standpoint, a "good company" is one that is:

> *transparent* in their cost. They [are] easy to deal with – *purposefully* – not just easy because it's an easy thing but purposes. Let's let me *go out of my way* to make your life easier. You're spending money. I'm going to give you that service – that's part of *my service*. *Fair* to their employees and workers. *Fair* and *responsible* to environment. *Fair* and *responsible* to their neighborhood area. All of those would speak to me saying this is a *good company* (emphasis added).

As shown in Figure 3, in elaborating this conception, the chef described his approach to managing his kitchen in terms of the need to create a (1) *"good place*" where "people like working" in order to support "longevity" among employees ("not a revolving door"). In so doing, the chef contrasted his orientation to that of a co-worker who, expecting workers to be motivated for continuous advancement, expressed criticism that some workers had been working the same position for over 30 years (i.e., "Why are they still doing the same job?). The chef identified the goal of fostering an environment to create "stable, happy people" as an important objective – one in which "some people move up quickly, some people move up slowly", but also with "people [who] are taking care of their families, doing what they need to do." In this regard, the chef talked at considerable length about his attempts to (2) *nurture the development of employees*. For the chef, nurturing employees was not simply a matter of teaching them kitchen skills. Instead, the chef spontaneously described several examples of his willingness to "find somebody who has the ability to get out of [bad life situations] and succeed", indicating that, "if I can help them with that I would." In this regard, the chef continuously invoked the moral value of *care* for his employees, not simply to as employees of a business, but as people with needs and concerns of their own.



GROUPS
(7)
Fair to Groups
I don't price higher for certain people -- ever. Whether a 'mom and pop' or an HVAC company comes for a party, their price is the same. Don't simply "squeeze them for all we can"...just because we can.
(8)
Responsiblity to Community
We reduce waste in my kitchen. I have a huge recycle dumpster, a very small trash dumpster and a big pile of compost...For the environment, if we don't have clean water and clean air and healthy people...
(6)
Fair Pricing
Like an airline. There is a certain window. So you booked far enough in advance? It's cheap with plenty of rooms Then you have a time where it starts filling out filling up and then supply and demand shifts. So to charge more at that point. It's the norm, and I'm okay with that.
VIRTUOUS PERSONHOOD & ETHICAL EXCHANGE
A good company is like a good person. I take care of my team and staff. A good company is fair to their employees; transparent in their costs, is purposefully easy to deal with. Fair and responsible to environment and to their neighborhood area. If you are a good person and do the right thing, it will help both the other (clients, workers) and the business.
(1)
Create a "Good Place"
Create a good place with longevity where people like working. People are taking care of their families, doing what they need to do.
CONCERN/ FEAR FOR SELF
(5)
Profit
Ultimately a business exists to make profit
CONCERN FOR OTHER
(4)
Self-Interest
The lower unemployment rate is not wonderful for employers. It makes it difficult to find people. Hiring is huge investment of time and money to hire and train and get them all set up. It's a lot.
(3)
Virtue
Taking care of staff
Ethical Exchange
Self-Interest
Helps me in the business
Care
Helps staff
(2)
Nurture Employee Development
When I find somebody with the aptitude and that I can honestly get a good feeling of their general outlook. If I judge them to be good person as a good solid person. In those cases, I'm willing to take a chance. To find somebody who has the ability to get out of [a bad situation] and succeed. If I can help them with that I would.
INDIVIDUAL

Figure 3: The Chef: Virtuous Personhood and Ethical Exchange

At the same time, while care figured prominently in the chef's discourse, he also pointed out the ways in which care for his employees helped the business itself. This is indicated at point (3) in a structure we have called the *virtue triad*. Here, invoking some standard for being a virtuous person or business, chef explained how invoking some standard of *virtue* motivates acts of *care* which also function to support the economic interests of the business. For example, he chef (3) described that "I *take care of my team and my staff* (virtue) in a way that *helps them* (act of care) as much as it *helps me in the business* (self-interest). This type of triadic structure occurred several times in the chef's narrative (see below). In this regard, the chef also made reference to the desire to care for employees out of (4) a need to attract and retain skilled workers (self-interest). He observed, "the lower unemployment rate is not wonderful for employers. It makes it difficult to find people." The chef also invoked "self-interest" in explaining the role of (5) *profit* in his approach to management. He said, "ultimately a business exists to make profit. The rest of that stuff [moral values such as virtue, care, etc.) falls *under that* or *in between* that, because if we make, if we're making money and have the ability to pay our people better and maybe put more people so they don't have to work so hard." Note here, however, that as soon as the chef invokes the concept of profit, he links it explicitly to his sense of the purpose of profit: that is, profit is needed to pursue some sort of good – in this case, the pay employees more or make their jobs easier. These sentiments show how, as implied in the structure of the (3) virtue triad, the chef organizes his thinking around different moral values that interpenetrate each other. The chef refers to this directly in his statement that "in my mind all of that rolls into the same. I think that's something that's not at all exclusive of the other definition."

The chef is charged with establishing pricing for large banquets housed at the hotel. In response to the question, "how do you price? Do you price for different people?", the chef replied "I don't. I don't price higher for certain people. *Ever*. So, mom and pop, an HVAC company comes for a party, their price is the same." In expressing this sentiment, the chef expressed his concern for (7) *fairness* in the treatment of different groups. At the same time, he acknowledged that (8) pricing differentials were *fair* in some situations. For example, in setting rates for hotel rooms, he suggested that it was acceptable to modify rates for rooms as a function of when reservations were made. Rooms rented well in advance could be charged at a lower rate than rooms rented within weeks of intended occupancy; rooms rented on the day of occupancy could be lower still, in order to ensure the room does not remain vacant. At the same time, the chef expressed distaste with the practice of taking advantage of customers during in the context of a seller's market, that is, the "attitude of 'they're coming anyway, let's squeeze them for all we can.'" In so doing, he expressed a desire for fairness both the customers and to the self-interest of the company. Further, the chef noted his willingness to give discounts for banquets for groups finances was demonstrably limited. However, he expressed a deep unwillingness to provide discounts to companies that he perceived had the means to pay listed prices. He explains his distaste, however, not simply in terms of fairness but instead in terms the ethics of relationship. In responding to companies of means that ask for deep discounts, the chef explains, "[We have] published pricing. And you want to come to business with us and you have shit tons of money. What makes you think or who do you think you are to then squeeze us?... you may only want to spend that [amount], but I'm almost like 'how dare you ask me for that kind of discount consideration?'" Here, the chef appears to experience the aggressive actions of a company of means not in terms of an abstract concept of fairness, but in terms of a lack of care or consideration in the relationship between the chef (and his company) and the client.

A final issue involves the chef's spontaneously expressed commitment to community issues as part of his conception of a virtuous business. Invoking (8) a sense of *responsibility* to the environment, the chef made reference to his rigorous desire to limit waste in the kitchen, for the purpose of ensuring "clean water, clean air and healthy people." When asked, "why should you care about that as a business? [Isn't that] kind of something 'over there'?", the chef responded, "No I think more business owners and business managers need to. You cannot 'if it doesn't bother me because I live in this part of town away from the dump.' It still bothers my town or my state, my country or my world."

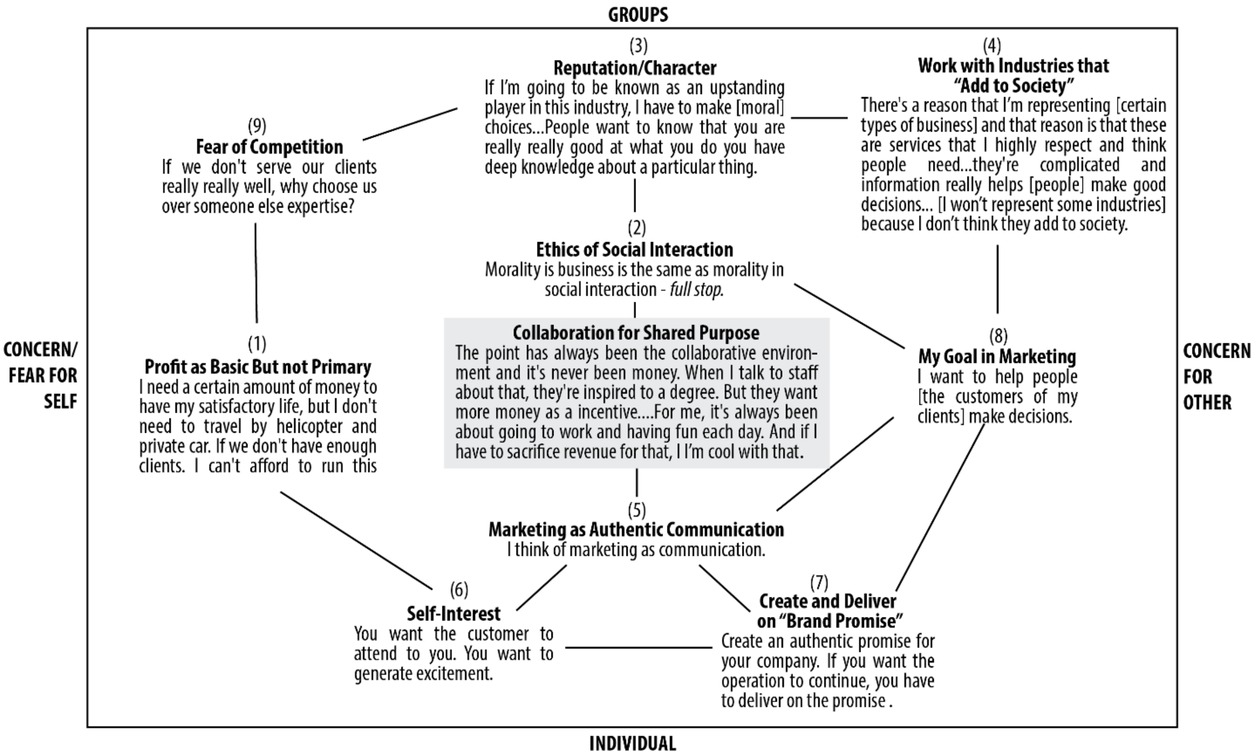
The Marketer: Collaborative Social Purpose

Morality in business is the same as morality in social interaction - full stop.

While consumers tend to believe that marketing plays a positive role in making people aware of products, they also believe that marketing serves the interests of business at the expense of those of consumers (Barksdale & Darden, 1972; Heath & Heath, 2008; Kashif, Fernando, Altaf & Walsh, 2018). The owner of the marketing firm was adamant that while mistrust toward marketers exists, moral marketing is not a contradiction in terms. Unlike both the dentist (and to a lesser extent, the chef), the marketer does not identify *profit* as the primary motive for a business. As shown in Figure 4, for the marketer, (1) while profit is *necessary*, but it is not the *purpose* of the business. The purpose of a business is to form a collaborative unit for the purpose of advancing some valued purpose:

> [The purpose of my business has] always been a *collaborative environment* and it's never been *money*. When I talk to staff about that, they're inspired by that to a degree, but they want more money as an incentive...But I'm not motivated by that. I need a certain amount of money to have my satisfactory life, but I don't need to travel by helicopter and private car. So to me, it's always been about going to work and having fun each day…. And fun to me is having challenging work…. And if I have to sacrifice revenue for that, I'm cool with that.

Operating from this point of view, the marketer was explicit that (2) "morality in business is the same as morality in social interaction." Profit is necessary in the sense that the operation "has to be profitable for it to keep going." However, the profit exists so that the business can "have the client coming with a particular challenging situation that we're trying to fix or answer." At the same time, (3) the companies that he works for must be those that "add to society." The marketer indicated that he explicitly chose to work in particular industries because "these are services that I highly respect and think people need," and that he would not represent clients – such as the alcohol industry – which he felt do not "add to society." In this way, he is in the business of (4) providing "information that really helps [people] make good decisions."



GROUPS
(3)
Reputation/Character
If I'm going to be known as an upstanding player in this industry, I have to make [moral] choices...People want to know that you are really really good at what you do you have deep knowledge about a particular thing.
(4)
Work with Industries that "Add to Society"
There's a reason that I'm representing [certain types of business] and that reason is that these are services that I highly respect and think people need...they're complicated and information really helps [people] make good decisions... [I won't represent some industries] because I don't think they add to society.
(9)
Fear of Competition
If we don't serve our clients really really well, why choose us over someone else expertise?
(2)
Ethics of Social Interaction
Morality is business is the same as morality in social interaction - full stop.
Collaboration for Shared Purpose
The point has always been the collaborative environment and it's never been money. When I talk to staff about that, they're inspired to a degree. But they want more money as a incentive....For me, it's always been about going to work and having fun each day. And if I have to sacrifice revenue for that, I I'm cool with that.
CONCERN/ FEAR FOR SELF
(1)
Profit as Basic But not Primary
I need a certain amount of money to have my satisfactory life, but I don't need to travel by helicopter and private car. If we don't have enough clients. I can't afford to run this
(8)
My Goal in Marketing
I want to help people [the customers of my clients] make decisions.
CONCERN FOR OTHER
(5)
Marketing as Authentic Communication
I think of marketing as communication.
(6)
Self-Interest
You want the customer to attend to you. You want to generate excitement.
(7)
Create and Deliver on "Brand Promise"
Create an authentic promise for your company. If you want the operation to continue, you have to deliver on the promise .
INDIVIDUAL

Figure 4: The Marketer: Collaboration for Shared Purpose

This statement is consistent with (5) the marketer's conception of the nature of marketing "as a form of communication." In elaborating this statement, the marketer noted the difference between this idea and the common notion that marketers are untrustworthy conduits of information. The interview asked whether "there are ways to market … without duping people." The marketer replied:

> the premise of that question is … of course, you are gonna lie as a marketer, but you don't have to. It’s this whole [assumption] that marketing is inherently a lie. I think of marketing as communication. I'm communicating with you now. As an academic, you [will] communicate to your audience through this journal. [Are the] words you choose to communicate your findings [a] lie? How do you describe me? … You're making a judgment on how you articulate. That’s what marketing is – we're making a judgment about how to articulate. We could be authentic; but [6] we also want to create excitement. You do [that] too when you write that article. [If you] use the most boring terms possible, nobody's going to read your article.

The marketer indicated that he could accept the proposition that “all communication is selling” in the sense that communication requires “getting someone to pay attention.” However, to make the “selling” morally legitimate, a company must be prepared to (7) “deliver on … the brand promise.” *Brand promise* is the image that the company puts forth to define what it is able to deliver to the customer. If, in the context of a given transaction, a business is able to deliver on the promise made in the process of selling, then the marketing of that product has been morally legitimate. The business has made an honest promise, and has kept it. It is thus (7) delivering on *brand promise* and (2) invoking the ethos of everyday social interaction that (8) a business can forge a *reputation* as an “upstanding player” who is “really really good at what you do you.” This reputation not only functions as a reflection of the character of the company, but also (9) gives clients a reason to do business with the company, as opposed to the other companies with which the business is in *competition*.

Conclusion: Morality and Moral Action as Evolving Relational Processes

We sometimes think of human psychological activity action as *first* behavior and *then* moral evaluation. Moral frameworks are often experienced as occupying a realm that is in some sense separate from everyday behavior – something related to extraordinary rather than ordinary human relations. As such, it is often seen as something that is “added onto” what we do rather than something that is part of the very process of what we do. Nowhere do we see this view more clearly than in the domain of business. Here, people often think that self-interest (e.g., the pursuit of profit; the preservation of the business itself) is the business of business, and that morality or ethics is something that is relevant after a stable profit structure has been established.

Moral relationalism maintains that moral values are properties not of some secondary or other worldly sphere of functioning, but instead are embedded and emergent outcomes of social relations themselves. The moment we enter symbolically-mediated social relations, our actions raise inescapably moral questions and function against the backdrop of already existing albeit constantly evolving moral frameworks. Contrary to what one might think if one were to examine the history of moral psychology in the latter part of the 20th century, the moral frameworks that frame human action are highly variegated – even within particular cultures. Among Western cultures that identify themselves as democracies, the ethos of rights, freedom and equality is dominant. However, while these moral values are foundational to democracy, they neither exhaust the range of moral values that mediate social life nor are they sufficient to sustain structures that promote human flourishing.

Moral selves are mediated by the capacity to engage in strong evaluation – higher-order evaluations of what we might pre-reflectively experience as first order goods. Self-interest is a first-order good that becomes transformed through the process of relating to others. Through our social relations, we can the capacity to use the meanings represented in socially-shared symbol systems to create higher-order moral representation of who we are and who we believe we should become. In this way, our selves become transformed and continue to become transformed as long as we find ourselves immersed in novel forms of experience made possible by our relations to the social and moral other. In this way, adult development occurs within the arena of socio-moral relations to others. It is mediated in large part by the construction of increasingly powerful, integrated systems of moral belief and action that are founded in relations between and among both individuals and social groups.

A Systematic Review of HeartMath© Interventions to Improve Psychological Outcomes in Individuals with Psychiatric Conditions

Dr Lucy Field[1], Dr Mark Forshaw[2], Dr Helen Poole[3]

Abstract: Background and objectives: A systematic review was undertaken to assess the effectiveness of HeartMath, heart rate variability biofeedback (HRVB) intervention studies within a variety of psychiatric conditions. **Design and methods:** Seven databases, including Web of Knowledge, Medline, Psych Info, Cinahl, Psych articles, Web of Science, the Cochrane Library and grey literature, were searched for suitable articles. Of the 1,701 citations identified, eight studies that utilised HeartMath HRVB interventions with psychiatric patients were included in the final analysis. A total of 64 patients aged 12-96 across a range of psychiatric conditions were examined in the systematic review. **Results** The review cautiously indicates that some groups of patients with psychiatric conditions report psychological improvement following HRVB HeartMath training. **Conclusions** These studies provide some evidence that HeartMath, HRVB interventions are promising in supporting beneficial outcomes for individuals with psychiatric conditions. The review points to future directions for HRVB interventions using the HeartMath technology.

Keywords: Coherence, HeartMath, heart rate variability, heart rhythms, psychiatric disorders.

Declarations

The main author completed this work as part of a Professional Doctorate in Health Psychology and no funding was obtained. The researcher is a qualified HeartMath coach but there were no conflicts of interest or competing benefits throughout any of the research.

---

[1] **Dr Lucy Field** is a Health Psychologist in the UK. This research was completed as part of a Doctorate in Health Psychology at Liverpool John Moores University. Dr Lucy Field has a keen interest in mind-body medicine and ways in which this can be implemented in healthcare.

Introduction

The structure of the National Health System (NHS) mental health service in the UK is changing, pushed to capacity and under-resourced. The Global Mental Health Action Plan (2013-2020) has called for improved access to innovative and cost-effective interventions for treating psychiatric conditions (Avey et al., 2003; Lancet Global Mental Health Group, 2007; Saxena, Funk, & Chisholm, 2013).

Current interventions for treating psychiatric conditions are typically pharmacological including anxiolytics (e.g., pregabalin), anti-depressants (e.g., Selective serotonin reuptake inhibitors (SSRIs) and antipsychotics (e.g., olanzapine) which manage and reduce the intensity of symptoms (Predictable, 2006). Some of these medications aim to target and relax the nervous system (e.g., benzodiazepines), but due to some severe side effects and addictive properties, they are not advised long-term (Baldwin et al., 2013). Individuals can become reliant on these medications which can impact on their levels of self-esteem and self-efficacy which may lead to poorer health outcomes (Austin-Ketch et al., 2012; Zimmermann et al., 2012).

More recently, primary and secondary care providers are actively encouraged to promote an individual’s control, choice and responsibility in managing their health (Leng, Baillie, & Raj, 2008). Hence, patient interest in alternative and complementary interventions has increased dramatically, one of which is Heart Rate Variability Biofeedback (HRVB) (for further information on other mind-body interventions, please refer to Park, 2013).

Heart Rate Variability (HRV) has been suggested to be an indicator of physiological stress and functioning of the nervous system and is measured by examining the beat-to-beat variation in the heart rhythm patterns (Edwards, 2020; McCraty, 2017). Research has revealed that low HRV levels are associated with psychopathological states such as anxiety (Thayer, Friedman, & Borkovec, 1996), depression (Beevers, Ellis, & Reid, 2011) and rumination (Brosschot, Van Dijk, & Thayer, 2007). In comparison, high HRV readings have been indicative of improved physical and mental health (Lehrer et al., 2006; Henriques et al., 2011; Ratanasiripong et al., 2015; Zucker et al., 2009; Kotozaki et al., 2014).

The use of HRVB interventions has expanded in popularity in more recent years for implementation in psychiatric conditions (Kapitza et al., 2010). Thus, interventions which target dysfunctional physiology from a ‘bottom-up’ perspective have demonstrated that patients are more able to identify and self-regulate their nervous systems, to calm challenging physical and mental symptoms, and increase physiological coherence (Leyro 2019; Pal Singh & Kaur, 2007; Kemp et al., 2012; McCraty et al., 2012). Coherence arises during positive emotional states when breath, heart and blood pressure become entrained. It is distinguished by a heart rhythm pattern of raised amplitude in low frequency heart rate variability of around 0.1 Hz, demonstrating synchronisation between the parasympathetic and sympathetic divisions of the autonomic nervous system (McCraty & Shaffer, 2015).

Due to the upsurge of interest in HRVB interventions and psychiatric conditions, there have been several reviews. Schoenberg & David (2014) examined 63 biofeedback intervention articles for use with psychiatric disorders. They revealed that 80.9% reported some clinical improvement, of which 65.0% were statistically significant (p<.05), concluding that biofeedback may be useful for psychiatric use. However, they examined a range of different biofeedback interventions (e.g. electroencephalography, electromyography, HRV and electrocardiography) and therefore, it is unclear if some types of biofeedback are more effective than others.

A recent meta-analysis also found a significant reduction in subjective reports of levels of anxiety and stress associated with HRV biofeedback training with substantial effect sizes evident in both within and between-group designs (Goessl, Curtiss, & Hofmann, 2017). The findings from the meta-analysis suggest that HRV-BF interventions are effective at reducing psychological measures of stress. However, the outcomes are sensitive to social desirability and methodological variance, therefore, there is a need to provide more objective measures such as physiological HRV improvements to validate the treatment effectiveness of biofeedback interventions (Van der swan et al., 2015).

Very recently, Poleszak et al. (2019) conducted a review examining the psychological and psychiatric benefits of biofeedback interventions in 23 articles. They concluded that HRVB is an effective therapy for use in depressive disorders, insomnia, ADHD and anxiety disorders. However, there was limited information available about the breakdown and quality of each study, research design and type of HRVB implemented. Therefore, drawing conclusions and evaluating the more detailed aspects of the systematic review is limited.

Collectively, these previous systematic reviews have demonstrated that HRVB interventions can be applicable in improving psychiatric outcomes; however, as already mentioned, there are different methods to measure HRV biofeedback. Of particular interest for this review is examining heart rate variability coherence as measured by HeartMath technology.

The Institute of HeartMath is non-profit organisation that has a mission and vision of promoting education, health, personal, social and global coherence research (Edwards, 2020). There have been no systematic reviews that have examined this type of HRVB only. HeartMath HRVB interventions employ a combination of psychological, physiological, behavioural and cognitive strategies to empower and educate individuals about the workings of their autonomic nervous system (Institute of HeartMath, 2014). Using technology such as the emWave®Pro Plus and the Inner Balance™, the individual receives immediate feedback via a sensor attached to the ear which displays their physiology via a visual format (e.g., on their mobile phone) and enables self-regulation in the moment initiated by changes in breathing or mood (Institute of HeartMath, 2014, Ratanasiripong et al., 2010).

This systematic review aims to build on, and advance knowledge of HRVB interventions using HeartMath technology and bring innovation and new direction into the psychiatric system.

Objectives

Review Questions

1. Are HeartMath interventions effective at improving psychological outcomes in patients with psychiatric conditions?

2. Do research studies report HRV coherence pre-post intervention?

Study Design

In order to gain clarity for the search terms, the acronym PICO was implemented for the review, see below for the breakdown (Higgins & Green, 2011).

PICO
Population: Psychiatric
Intervention: HeartMath HRVB
Control: Control, comparison or none

Outcomes

1. Change in psychiatric outcome measures.
2. To identify whether changes in HRV coherence values are reported

Methods

Protocol

This review followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement guidelines (Liberati et al., 2009).

Eligibility Criteria

Following PICO, eligibility for inclusion in the systematic review consisted of any HeartMath intervention with individuals who have a psychiatric condition. All English language databases from years 1971- to present-day were searched that included published, unpublished and literature.

Inclusion Criteria

1. English published work
2. Any age from 12 years old
3. Psychiatric disorder
4. HeartMath HRVB intervention
5. HRV coherence as measured by a phonograph, ear or fingertip measurement

Exclusion

1. Any other HRV biofeedback measurement that is not HRV coherence as measured by HeartMath technology.

2. Any conditions which are known to affect cognitive abilities to some degree, e.g., dementia, autism and Asperger’s syndrome were excluded.

Information Sources

Seven different electronic databases including Web of Knowledge, Medline, Psych Info, Cinahl, Psych Articles, Web of Science, the Cochrane Library and grey literature were searched for English articles between the dates 01/08/19 and 12/02/20. A backward search was also completed by examining the suitable articles' reference list and further, recognised authors were contacted to gain access to potentially relevant articles for more information. These search strategies are in line with best practice to gain a robust search strategy for the systematic review (Forshaw, Tod & Eubank, 2018; Liberati et al., 2009).

Search

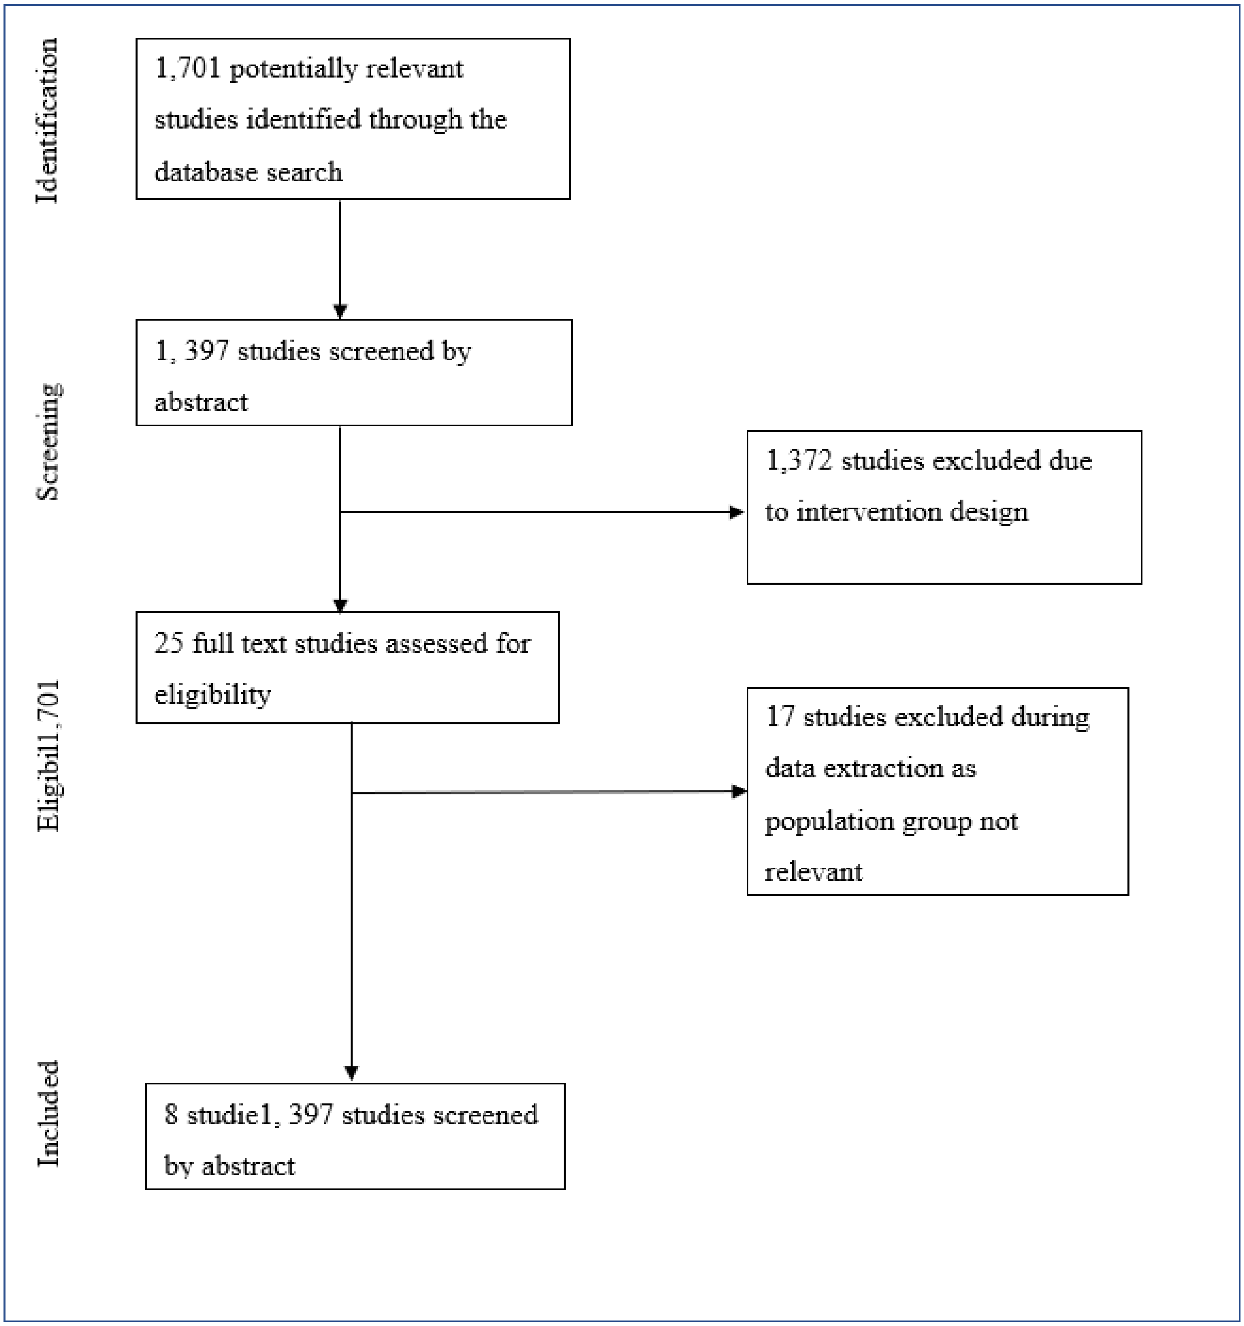
The following search terms were used for all databases:

"Heart rate variability biofeedback" OR "heart coherence" OR "Respiratory sinus arrhythmia" OR "HRV" OR "RSA" OR "resonance frequency biofeedback "AND anxiety OR "anorexia nervosa" OR "bipolar affective disorder" OR "depersonalisation disorder*" OR "personality disorder*" OR depression OR "eating disorder*" OR "bulimia nervosa" OR "binge eating disorder" OR "psych* disorder*" OR "psych* condition*" OR "obsessive-compulsive disorder*" OR "OCD" OR "MDD" OR "panic disorder*" OR "post-traumatic stress disorder*" OR "PTSD" OR "psychiatric disorder*" OR "psychological disorder*" OR "psychopathology" OR psychosis OR schizophrenia OR "borderline personality disorder*" OR addiction AND HeartMath Intervention*

Study Selection

The search strategy initially produced 1,701 articles, 304 of which were duplicates leaving 1,397 to be reviewed by title and abstract. 1,372 were excluded, the primary reason for exclusion was that HeartMath technology was not used in the study, leaving 25 full-text studies assessed for eligibility. Seventeen studies were excluded during data extraction as either the population group was not appropriate, or the study was not using a HeartMath protocol leaving a total of eight studies included in the review, see Figure 1 for the PRISMA flow diagram.

Eligibility for inclusion was rated by the first author and then moderated blindly by the second and third authors. Disagreements were negligible and were discussed leading to minor re-ratings due to emerging novel interpretations of the criteria in relation to the papers being considered. None of the small amendments led to a change in the inclusion/exclusion status of a paper.



Identification
1,701 potentially relevant studies identified through the database search
Screening
1, 397 studies screened by abstract
1,372 studies excluded due to intervention design
Eligibil1,701
25 full text studies assessed for eligibility
17 studies excluded during data extraction as population group not relevant
Included
8 studie1, 397 studies screened by abstract

Figure 1: PRISMA flow diagram for study inclusion

Risk of Bias in Individual Studies

Quality and risk of bias in the studies were measured using The Effective Public Health Practice Project (EPHHP) tool, which was developed explicitly for use within public health professions and therefore, appropriate for this review. All of the studies were scored using a ‘yes’, no’ or ‘can’t tell’ response system for the six component ratings on *selection bias*, *study design*, *confounders*, *blinding*, *data collection measures*, *withdrawal and dropouts.* A global rating for each paper was then decided and classified as *strong* (if no weak ratings in any of the components), *moderate* (if there were one or more weak ratings) and *weak* (if there were two or more weak ratings). This tool has been used effectively in a substantial number of similar reviews (EPHPP, 1998).

Data Collection Process

A data extraction sheet was employed to record specific information on each study including; (1) first author and year of publication, (2) country, (3) characteristics of participants (category of the psychiatric condition, sample size and gender), (4) type of design, (5) intervention condition (including frequency and length of HRVB sessions), (5) primary outcome measures (psychological or psychiatric measures and physiological HRV coherence data if provided), (6) results following intervention (psychological and physiological if reported).

Results

Study Selection

Eight studies met all the inclusion criteria for the systematic review, see Table 1 for a detailed breakdown of the study characteristics, design and specific outcomes.

Characteristics of Included Studies

Countries

Out of the eight studies, five were published in the USA (Lande et al., 2010; Ginsberg, Berry, & Powell, 2010; Beckham, Greene, & Meltzer-Brody, 2013; Reyes, 2014; Jester, Rozek, & McKelley, 2019), the remaining in different countries including France (Trousselard et al., 2016), Netherlands (Hartogs, Bartels-Velthuis, Van der Ploeg, & Bos, 2017) and Canada (McAusland, & Addington, 2018).

Study design

Amongst the eight included studies, the methodological study design varied. The most common research design was a within group with five studies employing this approach (Beckham, Greene, & Meltzer-Brody, 2013; Reyes, 2014; Trousselard et al., 2016; McAusland, & Addington, 2018; Jester, Rozek, & McKelley, 2019). There were two quasi-experimental designs (Ginsberg, Berry, & Powell, 2010; Lande et al., 2010) **and** one cohort study (Hartogs, Bartels-Velthuis, Van der Ploeg, & Bos, 2017).

Of the eight studies, five were pilot studies (McAusland, & Addington, 2018; Trousselard et al., 2016; Beckham, Greene, & Meltzer-Brody, 2013; Lande et al., 2010; Ginsberg, Berry, & Powell, 2010)

Participant Characteristics

Sixty-four psychiatric patients in total were recruited across the eight reviewed studies, age range 12-96 years old. Three studies included patients with PTSD (Ginsberg, Berry, & Powell, 2010; Lande et al., 2010; Reyes, 2014) and three different studies included patients with a range of psychiatric conditions (Beckham, Greene, & Meltzer-Brody, 2013; McAusland, & Addington, 2018; Jester, Rozek, & McKelley, 2019). The remaining studies included specific psychiatric conditions; schizophrenia (Trousselard et al., 2016) and major depression (Hartogs, Bartels-Velthuis, Van der Ploeg, & Bos, 2017).

Sample Sizes

There was a range of sample sizes in the research design ranging from the highest, 38 participants (Lande, 2010) to the least which was seven (Hartogs, Bartels-Velthuis, Van der Ploeg, & Bos, 2017).

Three of the studies contained 100% male patients (Ginsberg, Berry, & Powell, 2010; Lande et al., 2010; Reyes, 2014), one study used 100% female patients (Beckham, Greene, & Meltzer-Brody, 2013) and the rest were mixed-gender (Trousselard et al., 2016; Hartogs, Bartels-Velthuis, Van der Ploeg, & Bos, 2017; McAusland, & Addington, 2018; Jester, Rozek, & McKelley, 2019).

Intervention

The intervention lengths and training protocols varied in each research design. As displayed in Table 1, the number of intervention minutes that participants completed with a researcher/psychologist or biofeedback therapist ranged from 20 minutes (McAusland, & Addington, 2018) to the highest training of HRVB up to 720 minutes (Trousselard et al., 2016). The number of sessions ranged from one (McAusland, & Addington, 2018) to the most, 12 sessions (Trousselard et al., 2016) with the majority ranging between 6-12 sessions (Lande et al., 2010; Reyes, 2014; Jester, Rozek, & McKelley, 2019; Hartogs, Bartels-Velthuis, Van der Ploeg, & Bos, 2017).

Outcome Measures

Across the eight selected papers, studies varied greatly regarding the measures used as there was a range of different psychiatric conditions. The outcome measure used included; The PTSD Checklist (PCL) (Ventureyra et al., 2002), State-Trait Anxiety Inventory for Adults (STAI-AD) (Spielberger, 1983), Beck Depression Inventory-II (BDI) (Beck, Steer, & Brown, 1996), Scale of Prodromal Symptoms (SOPS) (McGlashan et al., 2001), Kessler Psychological Distress Scale (K10) (Kessler et al., 2002), Information Processing test battery (ATTN/IM) (Vasterling et al., 2002), Zung Self- Rating Anxiety Scale (SAS) (Zung, 1971), Zung Self-Rating Depression Scale (SDS) (Zung, 1965), the Positive Outcome list (POL) (Appelo, 2005), Spielberger State-Trait Anxiety (STAI) (Spielberger et al., 1983), Warwick Edinburgh Mental Well-Being Scale (WEMWBS) (Tennant et al., 2007), Linear Analog Self-Assessment (LASA) (Locke et al., 2007), The Positive And Negative Syndrome Scale (PANSS) (Guelfi, 1997; Kay et al., 1987), Freibury Mindfulness Inventory-14 (FMI) (Walach et al., 2006), Trail Making Test – Part A (TMT-A) (Reitan, 1995) and The Derogatis Stress Profile (DSP) (Derogatis, 1987).

Effectiveness of HRVB interventions

Primary Outcome

The primary outcomes of the systematic review were to examine the psychological benefits of HRVB on individuals with psychiatric conditions. Overall, of the eight studies, seven reported some level of psychological benefit following the intervention; more details per psychiatric condition are reviewed herewith.

For individuals with PTSD the findings were mixed; the study by Reyes (2014) found significant reductions in PTSD severity (p<.001) in contrast to Lande et al. (2010) who found no significant differences in levels of PTSD symptoms (as measured by PCL) or depression (as measured by SDS) post-intervention. A critical methodological difference exists between these studies; for the Lande et al. (2010) study, participants received a maximum of 120 minutes of HRVB training. However, the session protocol is not clear, compared to that of Reyes (2014) who completed the sessions over eight weeks and asked individuals to engage in daily practice. The third study with a PTSD population by Ginsberg, Berry, & Powell, (2010) did find significant improvements in the information processing (ATTN/IM) markers p<.05, but they did not include post measures on PTSD symptoms; therefore, it is hard to remark on PTSD symptomatology.

Three different studies recruited patients with a range of psychiatric conditions which examined collectively reveal some psychological improvements following HRVB but will be discussed separately in more detail. Beckham, Greene, & Meltzer-Brody (2013) recruited female patients who were suffering from severe perinatal anxiety and depression and found significant reductions on levels of anxiety (STAI), improvements in mental wellbeing (WEMWBS) and quality of life (LASA) (p<0.05) following the HRVB intervention. The study by McAusland, & Addington (2018) recruited patients with anxiety and who were high risk for psychosis, and results were a little less clear. They found clinically significant psychological reductions but only in some aspects of dysphoric mood and stress responses (as measures by SOPS) p <.01 but not for anxiety (SAS) or distress (K10). However, the individuals in this study only received 20 minutes of HRVB with a researcher and instead completed the rest of the training alone at home. The most recent study by Jester, Rozek, & McKelley (2019) recruited older adults with a range of psychiatric conditions and found clinically significant reductions in depression (BDI) p<.001 and anxiety (STAI-AD) p<.05. There was also a significant increase in attentional skills as measured by the TMT-A (p=.001), which is strong evidence for the effectiveness of HRVB interventions on psychiatric symptomology.

The remaining two studies were focused on one psychiatric condition only. The study by Hartogs, Bartels-Velthuis, Van der Ploeg & Bos (2017) recruited patients with major depression and reported that 71% of patients reported a reduction in depression levels. However, no value of statistical significance or valid psychometric measures were employed and findings were based on a single item. The final study by Trousselard et al. (2016) recruited schizophrenic patients and following an HRVB intervention found significant improvements in anxiety (STAI) and mindfulness (FMI) (p<.05). However, no significant differences in all other measures of stress and wellbeing were found (as measured by PANSS, WEMWBS and DSP).

Secondary Outcome

The secondary outcome of the review was to examine if HRV coherence levels were reported. Out of the eight studies, only one study provided statistical analysis of HRV coherence; Ginsberg, Berry, & Powell (2010) found HRV coherence was achieved by all participants with PTSD post-HRVB training which was significant at the <5% level**.**

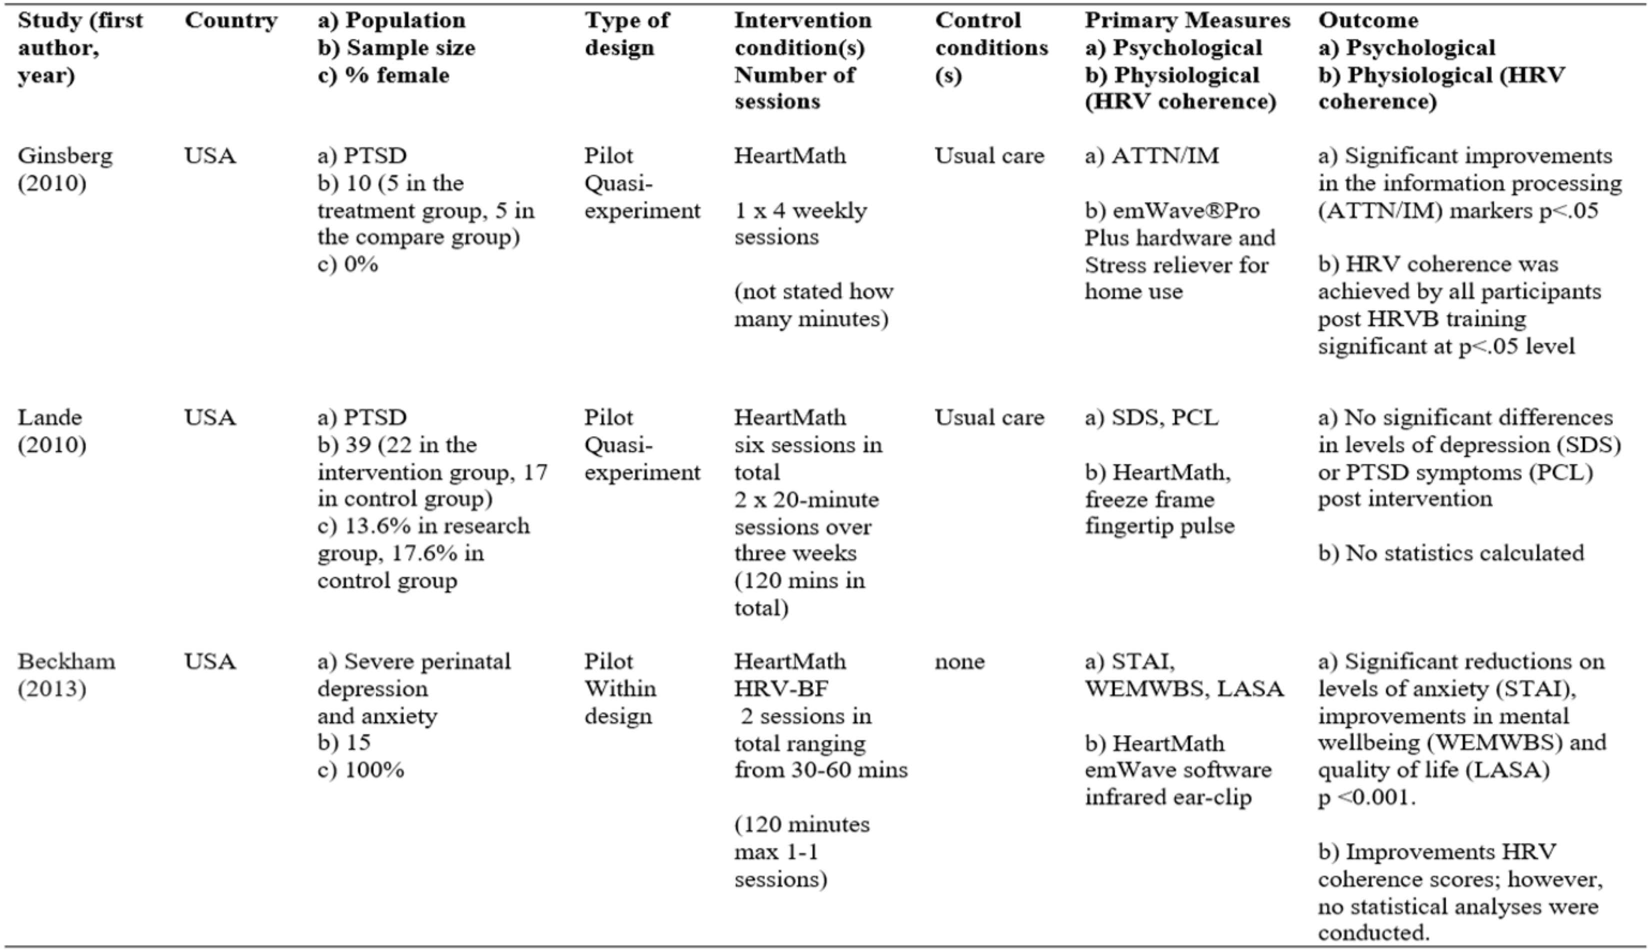
Two studies reported an improvement of HRV coherence levels following the intervention but did not conduct an in-depth statistical analysis (Reyes, 2014; Beckham, Greene, & Meltzer-Brody, 2013). Further, five studies did not refer to HRV coherence as an outcome measure at all (Lande et al., 2010; McAusland, & Addington, 2018; Jester, Rozek, & McKelley, 2019; Trousselard et al., 2016; Hartogs, Bartels-Velthuis, Van der Ploeg, & Bos, 2017).

Risk of Bias

The EPHHP risk of bias measure emphasized several weaknesses within some of the review papers. The main weakness was in study design and blinding which is expected due to five out of the eight studies being pilot studies (McAusland, & Addington, 2018; Trousselard et al., 2016; Beckham, Greene, & Meltzer-Brody, 2013; Lande et al., 2010; Ginsberg, Berry, & Powell, 2010). Regarding selection bias, all studies were classified as *medium* or *strong* as they were likely to be somewhat representative of the target population. Six of the eight studies were rated moderate for *data collection measures* as most of the tools were reliable and valid.

Overall, seven out of the eight studies were given a global rating of ‘weak’ mainly due to research design. The most common research approach involved a within-groups design with five studies employing this approach (Beckham, Greene, & Meltzer-Brody, 2013; Reyes, 2014; Trousselard et al., 2016; McAusland, & Addington, 2018; Jester, Rozek, & McKelley, 2019). There were two quasi-experimental designs (Ginsberg, Berry, & Powell, 2010; Lande et al., 2010) and one cohort study **(**Hartogs, Bartels-Velthuis, Van der Ploeg, & Bos, 2017) which are often subject to reliability and validity issues. However, all eight selected studies in this review demonstrated clear aims and research questions, utilised appropriate population groups, and had moderate levels of data collection and minimum attrition rate, (see Table 2 for more information).

Table 1. Study characteristics



Study (first author, year)	**Country**	**a) Population b) Sample size c) % female**	**Type of design**	**Intervention condition(s) Number of sessions**	**Control conditions (s)**	**Primary Measures a) Psychological b) Physiological (HRV coherence)**	**Outcome a) Psychological b) Physiological (HRV coherence)**
Ginsberg (2010)	USA	a) PTSD b) 10 (5 in the treatment group, 5 in the compare group) c) 0%	Pilot Quasi-experiment	HeartMath 1 x 4 weekly sessions (not stated how many minutes)	Usual care	a) ATTN/IM b) emWave®Pro Plus hardware and Stress reliever for home use	a) Significant improvements in the information processing (ATTN/IM) markers p<.05 b) HRV coherence was achieved by all participants post HRVB training significant at p<.05 level
Lande (2010)	USA	a) PTSD b) 39 (22 in the intervention group, 17 in control group) c) 13.6% in research group, 17.6% in control group	Pilot Quasi-experiment	HeartMath six sessions in total 2 x 20-minute sessions over three weeks (120 mins in total)	Usual care	a) SDS, PCL b) HeartMath, freeze frame fingertip pulse	a) No significant differences in levels of depression (SDS) or PTSD symptoms (PCL) post intervention b) No statistics calculated
Beckham (2013)	USA	a) Severe perinatal depression and anxiety b) 15 c) 100%	Pilot Within design	HeartMath HRV-BF 2 sessions in total ranging from 30-60 mins (120 minutes max 1-1 sessions)	none	a) STAI, WEMWBS, LASA b) HeartMath emWave software infrared ear-clip	a) Significant reductions on levels of anxiety (STAI), improvements in mental wellbeing (WEMWBS) and quality of life (LASA) p <0.001. b) Improvements HRV coherence scores; however, no statistical analyses were conducted.

Discussion

This systematic review examined the effectiveness of HeartMath interventions on psychological and physiological outcomes in individuals with psychiatric conditions. Previous reviews have identified the effectiveness of HRVB interventions within various psychiatric conditions (Schoenberg & David, 2014; Poleszak et al., 2019; Goessl et al., 2017). A systematic review by Schoenberg & David (2014) analysed 63 biofeedback intervention articles for use with various psychiatric disorders and found that 80.9% reported some clinical improvement, of which 65.0% were statistically significant (p<.05). The articles examined in the review included a range of biofeedback interventions (including electrocardiography, electroencephalography, electromyography and HRV) and therefore, it was undistinguishable if certain types of biofeedback are more effective than others.

A further meta-analysis by Goessl, Curtiss, & Hofmann (2017) reported significant reductions in subjective reports of levels of stress and anxiety associated with HRV biofeedback training. In addition, substantial effect sizes were evident in both between and within group designs with the authors concluding that HRV-BF interventions are effective at reducing psychological measures of stress. More recently, Poleszak et al. (2019) conducted a review examining the psychological and psychiatric benefits of biofeedback interventions in 23 articles. They concluded that HRVB is a successful therapy for use in anxiety disorders, insomnia, ADHD and depressive disorders.

Collectively, these previous systematic reviews have demonstrated that HRVB interventions can be applicable in improving psychiatric outcomes as a whole. The systematic review presented in this paper extends these findings of previous reviews and demonstrates that some groups of patients with psychiatric conditions report psychological improvement following HRVB HeartMath training. More specifically, HeartMath interventions appear to beneficial for a range of conditions including, PTDS, anxiety, stress, depression, and schizophrenia in a wide age range. More poignantly, Ginsberg, Berry & Powell (2010) report that the results from their pilot study for individuals with PTSD are promising in that although sample sizes were small, the effect size was large enough to produce statistical significance for some of the observed outcomes. In fact, they indicate that the statistically significant improvement in HRVB outcome measures is comparable to effect sizes produced by standard treatments for PTSD. This is in line with the study by Jester (2019), who also reports that HeartMath interventions were a significant predictor of changes in psychiatric symptoms and cognition and revealed large effect size decreases in depression, state anxiety, and trait anxiety.

In contrast, some of the studies reviewed do not show improvement in psychiatric outcomes following HeartMath interventions; one of the reasons for the discrepancy may be methodological. The length of the training protocol and the amount of personal practice in HRVB interventions could be one factor influencing clinical outcomes; for example, the study with the longest standardized training time was 720 min by Trousselard et al. (2016) compared to 20 minutes in the study by McAusland & Addington (2018). As discussed in the review by Schoenberg & David (2014), the HRVB literature lacks standardization, and although templates and protocols do exist (e.g., Lehrer et al., 2013), not all studies follow the guidelines or report HRV data. Further, a problem with the studies used in this review, and other HRVB studies generally, is that there is often no randomization or controlling for medication which has been found to affect HRV levels (Leyro, 2019).

The broader findings of HRVB interventions have been found to improve levels of HRV in respect of many physical health problems such as heart disease, hypertension, emphysema, insomnia, asthma, fibromyalgia, back pain and chronic fatigue (Paine et al., 2009; Lehrer et al., 2006; Hassett et al., 2007; Windhurst et al., 2017). Considerable improvements are also reported in objective health-related measures following HRVB training such as improved ANS function and balance (Tiller et al., 1996), and the cortisol/DHEA ratio (McCraty et al., 1998), immune system function (McCraty et al., 1996) and improved glycaemic regulation and cholesterol levels (McCraty, Atkinson, Lipsenthal, et al., 2003).

HRVB interventions may be effective to use alongside additional medical care and other psychological interventions such as CBT and therefore treat aim to treat mind-body health (Rusch et al., 2011). Practically, HRV biofeedback is comparatively easy to use, learn and teach. It is low cost and, the Inner Balance™ app recently developed by HeartMath can be used on smartphones, further reducing implementation barriers as it can be used in and out of the research and/or clinical setting. This type of stress management intervention may be effective in preventing high attrition due to being non-invasive, non-threatening and very person-centered (Van der Zwan et al., 2015).

Limitations

A criticism of this review is that five out of the eight studies were pilot studies, and further, seven out of the eight studies were classified as ‘weak’ concerning the risk of bias following assessment with the EPHPP scale. However, with the rise of interest in HRVB interventions, conducting preliminary analyses with pilot studies before proceeding to more costly and time-consuming interventions is not only essential but cost-effective. Some of the studies used in this review have highlighted that it is not always logistically feasible to conduct RCTs in inpatient or outpatient settings due to sampling size, duration of hospital stays, and acuity of illness (Eliopoulos et al., 2004). Although some of the studies are rated as weak they are endorsed as being suitable for review as the majority of the studies are pragmatic and realistic, for example that of Beckham, Greene & Meltzer-Brody (2013) who conducted their research in hospital settings with patients with severe psychiatric conditions which by the very nature of the design brings ecological validity to the research. However, without control groups, it is difficult to say with certainty that the improvements in psychological outcome measures are attributable to the usage of HRVB rather than regression to the mean, effects of time, social desirability and therapist bias.

All the eight studies endorsed the premise that HRVB is an alternative, non-pharmacologic, safe, therapeutic intervention ideal for patients who are more vulnerable or at risk of pharmaceutical complications. For example, the study by Beckham, Greene, & Meltzer-Brody (2013) recognized the use of HeartMath technology and the HRVB intervention for use with anxiety and depression given the increased fear about harmful side effects of pharmacologic treatments on a developing foetus. As recommended by Leyro (2019), HRVB interventions have strong potential that endorses future research and clinical dissemination.

Implications

With the structure of the NHS changing, it being seen as over-burdened, under resourced and pushed to capacity, there is a drive for individuals to improve their self-management and accordingly, primary care providers could actively promote self-regulation skills and include a system wide initiative to be proactive and promote individual wellness (Lemaire et al., 2011).

It is clear that coherence can affect our physiological, emotional, mental and physical health and these benefits extend further to improved cognitive functioning and enhanced optimal performance, perceptual processing and intentional behaviour (McCraty, Atkinson, Tomasino, & Bradley, 2009).

Future Directions

A significant finding in this review is to provide more structure and direction to future HRV coherence research using HeartMath technology. Designs should follow guidelines concerning psychophysiological research for use in experiment planning, data analysis and data reporting (Laborde et al., 2017; McCraty et al., 2015). The guidelines highlight the importance of using an instrument specific to measure physiological changes in HRV. The latest HeartMath technology, emWavePro Plus is a valid and reliable measurement tool to identify changes in HRV coherence pre-post intervention (Institute of HeartMath, 2014). The benefit of using the emWave®Pro Plus HeartMath technology is that detailed analysis of additional components in HRV, for example, low, very low and high-frequency measures are available (Institute of HeartMath, 2014). Furthermore, the utilisation of emWave®Pro Plus technology is specifically for healthcare professionals and is an easy way to inexpensively add standardized HRV coherence measures and assessment for research and clinical practice. Such assessments are available for use in a wide range of applications. These include quantifying HRV levels in relation to autonomic nervous system activity as well as identifying changes in HRV or coherence levels, and documenting any physiological baseline shifting over time (Institute of HeartMath, 2014). The review highlights the lack of HRV coherence data reported from researchers using the HeartMath technology and encourages a standardised format that would include three HRV coherence measures pre- and post-intervention. These include; resting HRV assessment (minimum five minutes) in which an individual is asked to sit quietly without talking; this provides a baseline HRV. The second assessment is the ‘stress preparation’, participants are invited to sit for three minutes as if they were preparing emotionally for an important upcoming event or activity and to focus their attention in the centre of their chest and experience a positive feeling such as care or appreciation for someone or some special place. The final assessment consists of a one-minute deep breathing assessment where the participant is encouraged to breathe as deeply and comfortably at the pace shown on a computer screen. By utilising this protocol, as recommended by McCraty, Atkinson, & Dispenza (2018), researchers could generate HRV coherence data that could be reviewed more accurately within and between research studies.

Conclusions

Overall, this systematic review provides reasonable evidence that HeartMath, HRVB interventions are promising for use in psychiatric conditions. Further randomised controlled trials are needed since the available evidence is notably lacking in these despite their gold standard status.

Cultivating Developmental Reflexivity: ART of Relational Inquiry Methodology for Self and Community Transformation

Hilary Bradbury[1] and Lara Catone[2]

Abstract: We introduce the paradigm of Action Research for Transformations (ART) as a methodology for developmental reflection and practice within the framework of constructivist adult developmental theory.

We illustrate a relational methodology that inquires how to cultivate self and community so that more of us may live our aspirations for love and power in relationship – including with Earth. This means taking intellectual insight into the realm of practice together.

The relational inquiry of ART invites us to consider the nature of inquiry itself and the need to not just understand but coproduce the kinds of transformations we understand to be necessary for a more sustainable, life enhancing world. Though it has many applications, it is offered here in the context of the cultural struggle to grapple with the transformation of power, especially among women and men, people of color and dominant minorities.

Keywords: Action research for transformation (ART), constructivist adult developmental theory, transformative learning praxis, reflexivity, relational power, gender, mutuality, post conventional science.

> Genuine power can only be grown, it will slip from every arbitrary hand that grasps for it; for genuine power is not coercive control, but coactive control. Coercive power is the curse of the universe, coactive power, the enrichment and advancement of every human soul.
>
> Mary Parker Follet, 1924

The Purpose of Inquiry

This paper argues that the call of our times, with its multiple interwoven social and ecological crises, demands more emphasis on how to coproduce participative change on our way toward a more sustainable, or life enhancing, world. Scholarly descriptions of our problems, abstract and depersonalized, while often helpful for understanding, are not enough to support tangible change in our personal and shared practice. We therefore introduce an orientation to fuller spectrum

---

[1] **Hilary Bradbury Ph.D**. is Editor in Chief of the Action Research journal and principal-curator at ActionResearchPlus (AR+) Foundation, a global community of participative action researchers. She advises educational institutions around the world in transforming their programmatic response to the social-ecological crisis of our times. She emphasizes the integration of research and practice, as action research for transformations, or ART.

knowledge in the form of an action-oriented methodology for knowledge co-creation and social change. We present it here as working hand in hand with constructivist adult developmental theories. Its goal is to liberate more of us to respond to the call of our social-ecological challenges by practicing more collaboration despite our differences.

Action research is the umbrella term that describes a variety of scholarly practice with a participative orientation to knowledge creation (Bradbury 2015). It contrasts with conventional objectivist scholarship. It is research conducted in the midst of practice with ongoing feedback loops between researcher-participants that foster mutual understanding, design improvement and tangible innovation. As a form of participative constructivism (Gustavsen, 2014), action research brings together action and reflection, theory and practice, with stakeholders to issues of pressing concern (Reason and Bradbury, 2000). Action research contrasts with conventional social research which offers primarily objective descriptions of outer reality and focuses on our problems (Fazey et al, 2018) for which solutions are rarely described.

Action researchers do not bring pre-packaged solutions. They, do however, bring catalytic diagnostic and facilitative tools as they also distill and document notable results. Convening community – relational spaces – is prerequisite. Stakeholders can then articulate their own answers and experiment with providing better outcomes in their own contexts. The repertoire of participative action methods is lengthy and diverse with many known in their own right as popular approaches, e.g., U-labs of Otto Scharmer (2007), appreciative inquiry methodology of David Cooperrider (Cooperrider and Whitney, 1999), the World Café process of Juanita Brown (Brown and Isaacs, 2005). Beneath the variety of form, we see across the methodologies that there is a relational, wholistic, and practical approach to knowledge creation (Bradbury, 2015). Further, the knowledge products developed from these methods call for and experiment with a wider variety of data than conventional research methods (Chandler and Torbert, 2003). Through individual and/or group action in the present, action research constructs a richer understanding of the past to help shape the desired future of stakeholders (Gergen, 2015).

Though objectivism is a hallmark of modernist science–with its many enlightened advances over theocratic forces of old–an elemental pitfall of distanced/objectivizing research is that its solutions to problems are prescribed without feedback from the very people involved with, or affected by, the change efforts. Turning the buzz of experience into objects of thought is what conceptual work is all about. Therefore, the turn to practice is post-conceptual, through and beyond it. Action research, anchored in a more relational perspective, includes two critical perspectives that help here. The first acknowledges and integrates subjective awareness of the self in relationship to the research. An action researcher might therefore inquire, *What assumptions or biases (some felt but not well worded) am I bringing that might influence this research?* The second perspective is an interpersonal inquiry that invites feedback from, and with, research participants and stakeholders as an intrinsic part of the process. The inquiry might include some version of *How do we embrace the value of our differences; how can our partial truths and gift accomplish more together?* Action research may be deemed successful to the degree that an inquiry itself is owned and proliferated by more stakeholders.

Action Research Transformations

Given our interest in transformation, we’re also interested in power dynamics, especially those that hold the status quo in place. The inclusion of subjective and interpersonal perspectives in action research allows for a methodology in which power is not only described at a distance, but rather becomes a process in which to engage transformation processes.

Transformation addresses the very values and logics that perpetuate problematic aspects that inhibit well-being among stakeholders to an issue. ART encourages the spirit of the call to “future forming” beyond qualitative description of our problems (Gergen, 2015). It is offered as a timely updating of our notions of knowledge and learning by redirecting the purpose of knowledge toward cocreating a life enhancing world.

ART, as a contemporary form of action research, integrates early insights about power available from the earliest articulation of pragmatism (Addams, 1902; Dewey, 1903; James, 1907), as seen in the opening quote from Mary Parker Follet. Follet understands power also as a creative, not just domineering, capacity that is generated through relationship among integrated, sovereign wholes. Her notion of “power-with” described a conjoining in mutuality. This formulation stands in contrast to ongoing notions of power simplified as coercive “power-over” which assumes either I, or you, have power but not both. The cultivation of “power-with” appears consequential for efforts to transform toward a more sustainable world.

Nearly 100 years later, the need for knowledge forms that are sensitive to understanding and coproducing “power-with” have only increased as society grapples with, and appears often stymied by, inherited coercive power. In the winter of 2017 and the summer of 2020, the #MeToo and Black Lives Matter movements each reached boiling points. A reckoning with how social power is exercised rang across the globe. We found ourselves seeing more clearly how gender, race, (and poverty, mental health, and environmental issues) interweave with inherited (power-over) power structures. The social change movements insist on new standards of behavior to reduce from predatory behaviors. This has also produced confusion, and not a little sanctimony and shunning in the rush to enforce what amounts to a significant interpersonal shift, dare we say, cultural revolution replete with denunciation.

What lies beyond unilateral power wielded through manipulation and force? ART offers a response that can harness post-conventional research minds toward the realization and practice of transformative mutuality. It is a practice that calls for reflexivity–asking us to turn the camera on ourselves as we gather data about our world. Leaders in the Black Lives Matter movement call out attention to the depersonalization by law enforcement of the communities they serve and show that it leads to problematic policing that criminalizes poverty and lack of community resources. Historically law enforcement acts on, rather than with. More generally we might say that knowledge creation anchored in reflexivity is best when integrating personal/reflexive *and* interpersonal/relational, *and* impersonal, often anonymous/objective information. The interweaving of first (me; subjective), second (us, inter-subjective), and third person (all of us, objective) perspectives thereby has the potential to grow those involved and empower participants in social change to shape the world of their aspirations (Bradbury & Reason, 2000). Our difficulty is often in weaving the feelings (of discomfort etc) from the subjective realm to the clarity of the objective. Next, we situate ART as a vehicle for adult constructivist developmental theory. In cultivating our capacity to uncover and work with our own subjectivity, we can access new clarity about the shared inquiry context, and clarity about our own involvement in the research.

Inquiry Itself is Developing

Constructivist adult developmental theory illuminates how we see and make sense of the world and therefore, inter alia, how we approach research. The basic proposition, elaborated by scholars such as Michael Commons, Susanne Cook-Greuter, Robert Kegan, Jane Loevinger, Jean Piaget, William R. Torbert and Ken Wilber, is that there is an invariant sequence of stages through which humans' meaning making of experience develops. The developmental stages of meaning making describe a primary worldview, or a center of gravity, from which a person makes sense of, and responds to, the challenges that life brings. Generally, the theory suggests an arc of unimpeded development of increasing flexibility, complexity, self-expression, tolerance, differentiation, and integration between the inner and outer worlds (Cook-Greuter, 2013). Less spoken of, but critical to working with our subjectivity, is that development fosters not new content (say blistering clarity and wisdom), but deepening capacity to confront our earlier, buried or shadow material, located in our own earlier developmental stages. Shadow is Jung's word for the unconscious aspects of the self that, when brought to conscious awareness, may be feared or denied, because they are counter to one's ethics, values, or intentions. Murray (2021) explains that cultural shadow resides in lower strata of the psyche "forgotten" by consciousness, but also connected with our own lifeforce – say capacity to play together and celebrate life, live sustainably within an ecosystem. Inquiry into our own shadow is necessary for living more fully amid deep pluralism. Personal and relational development becomes more tolerably within reach when we can hold perspective about a fuller me and us. Such inquiry can be deeply productive. And there will be inevitable fallback, especially under conditions that threaten our security.

In models of constructivist adult development, it appears that the transformational process of development does not occur by logic or cognitive reflection alone (Torbert et al., 2004), but rather as each person faces conundrums in everyday life that their current approach does not resolve. In this sense, constructivist adult development theories are integrative; people develop in dynamic relationship to self, other, language, culture, and external contexts (Cook-Greuter, 2013). As a person accesses new and more complex inquiries – often with the support of a learning community or guide – it is possible for a new worldview to emerge that interweaves thought, feeling, and action as they never before imagined. At early stages the individual tends to be self-protective whereas at later stages they become quite inclusive and multi perspectival. Each subsequent action-logic (Torbert's term for developmental stage) is gradually discovered–if at all–through a process of seeing through and thus questioning the taken-for-granted assumptions embedded in that action-logic and partially–but not totally–leaving it behind. Thus, each later action-logic includes, but is not limited to, the entire domain of the previous action-logics. As a person progresses through this kind of vertical development the transformation of their worldview reaches a higher vista offering an aerial view of their previous action-logics. Thus, at each new stage, or vista, gaining capacities and choice in the process.

Correspondingly, the types of research, enactments of power, and how we approach others are, to some large extent, shaped by our developmental stage. Torbert explains that earlier action-logics have us feeling compelled rather than liberated. In Torbert's work in the field of executive management it is shown that the assessment of developmental stages correlates with success for those executives who operate with later developmental stages (Rooke & Torbert, 2005). Their success is explained as an outcome of their capacity to exercise qualities of power that become increasingly mutual in nature, in turn associated with the capacity of the later action-logics to inquire beyond their ego-limits and thus to be able to exercise power on behalf of values beyond their own self-interest. Torbert explains that at later stages, the exercise of mutual power invites both oneself and others to transform. Consider creative industries in which innovation develops as a result of people finding solutions together. This happens not by superiors compelling subordinates to be creative but rather through something more akin to play. With regards to power, the fundamental move is from unilateral, power-over, to mutual, power-with; from hard power to soft power.

Key also in the literature of leadership development is the importance of reflection on experience as a prime route to growing ourselves, an insight that harkens back to the Socratic admonition to live an examined life. Reflection is a process of learning from by being with experience. In this the individual considers, thinks, and responds to a specific problem situation. In retrieving Mary Parker Follett and being intrigued by Torbert's work with executives, we suggest that reflexivity, is a type of conscious self-development that may be particularly enriched by inquiry into conflictual relationship. Reflexivity is a more ambitious and challenging process than cognitive reflecting as it becomes new patterns of relational practice. Reflexivity includes examination of one's own way of thinking, assumptions, and underlying patterns of values and worldviews, that results in new action together. It lies at the heart of the work we present that is experiential and experimental – making real life, beyond lab studies and executive suites, the arena for transformative learning.

Reflexivity in Mutual Inquiry

If knowledge is power, any transformative attempt must recognize the politics of reflexivity in knowledge creation processes. Culture is arguably enriched when reflexivity complements empirical-analytic, denotive knowledge. Our efforts with reflexivity are therefore also subjective, sometimes intuitive – thus bringing our own biases into awareness in a way that gives voice to more intuitive processes. Freinacht (2018) is useful here, suggesting three steps to reflexivity that require clarity about: 1) one's intention - articulated as something I am drawn to, passionate about (e.g., I am a vegan), 2) naming the positive halo of this intention (e.g., because I don't wish to perpetrate violence) 3) and also naming a potential shadow (e.g., because I have been treated as an object myself and don't wish to be complicit in doing this to any sentient beings). Jung, who originally defined and worked with shadow in his psychoanalysis practice, cautions us that unexamined, repressed parts of the psyche limit our capabilities and forge a gap between how we think of ourselves and what we enact (Jung & Hull, 1991). In developmental terms the shadow forms in our early years when, by necessity, we learned to be self-protective. As we develop, we can bring these shadows to the light. Otherwise, we bypass and become complicit in the ego protective nature of the shadow. As scholars, engaged in questions of what constitutes reality, perhaps we must look at shadow. And our turning the camera around on ourselves can continue through our life. Awareness of shadow may be supported by accessing non-conventional ways of knowing, (i.e., intuitive, more creative forms) to enrich our repertoire of rationally accessible knowledge. This type of knowledge integration may have an added benefit of acknowledging the value of heretofore marginalized forms of knowledge, such as women's ways of knowing, (Belenky, Clinchy, Goldberger, & Tarule, 2008), and power of sacred plant medicine (Nicolaides, 2021).

Developmental Case Studies

The following cases illustrate key issues of reflexivity that concern power. We will assess the quality of knowledge creation using seven quality choice points that conceptualize quality in action research as an appropriate combination of (1) **Articulation of purpose and objectives** which refers to the clarity of purpose with regard to intended knowledge creation through, and for, action in support of our collective thriving; (2) **Partnership and participation** which refers to the extent to and means by which participative values are evident in the relational component of research; (3) **Contribution to action research theory/practice** which refers to the extent to which the work builds on, and/or creates explicit links with extant knowledge; (4) **Methods and process** which refers to the extent to which the action research process and related methods are clearly articulated; (5) **Actionability** which refers to the extent to which the action research conveyed through the paper provides new ideas that guide action in response to need; **(6). Developmental Reflexivity which** refers to the extent to which self-location is acknowledged and brought to the inquiry; **(7). Significance** refers to the extent to which the insights have meaning and relevance beyond their immediate context in support of the flourishing of persons, communities, and the wider ecology.

Before introducing the ART cases, Table 1 simplifies and presents three developmental stages of relational power we use to analyze the cases. The first is unilateral in which relationship is self-centered and self-protective, an orientation developed in our earliest years and to which we may fall back under stress; the second is independent, more associated with the stages of early adult life. The third later interdependent, and rarer, stages—defined here as collaborative—and which allow for authentic co-creativity. Each stage corresponds with a capacity for a particular level of inquiry. The simplest is single-loop inquiry, which occurs at the level of action, a type of "fix it" mode that we use most of the time throughout life. Single loop inquiry is most available in the earliest stage of development and works on externally oriented changes in behavior. As we tend to be fused with our identities when operating from earliest stage (e.g., wife, mother, accountant) inquiry does not turn inward to disrupt these identities but stays external. Double-loop inquiry can occur at the later stages of action-logic, when one's identities, and the strategies that keep them intact, are able to be questioned and experimented. Double-loop inquiry is at play when questioning what needs to be fixed and why. In the formulations of action researcher Chris Argyris, single loop inquiry is like setting the thermometer to fix a room at a comfortable temperature, whereas double loop is asking what the best temperature is. Triple-loop inquiry is the most complex. It includes the first two levels, our behavior, and questions about best practice, and adds to the inquiry the awareness of cultural narratives, the larger context. Torbert et al, (2004) see it as the most reflexive level of inquiry because it involves attending to own attention and becoming able to see thoughts, behaviors, and intentions in the present moment and to experiment with changes as needed. To complete the metaphor of the thermometer, triple loop inquiry may involve enacting concern for climate change by accepting a less than comfortable temperature or deciding to devote a next stage of life to supporting a development of an entirely different form of energy. Working with these broad-brush outlines of developmental movements of power and relational wholeness we now offer illustrations of ART in the context of power dynamics in work contexts with an eye toward gender relations. Three cases follow, each serving to illustrate the complex implications for methodology as issues of reflexivity become salient.

Table 1: Developmental Levels of Inquiry and Power

Mode of Power	**Stage of Development**	**Inquiry**	**Power orientation**
Unilateral	Self (as separate and self-protective)	Zero inquiry	"It's all about my power over you or yours over me."
Independent	Relational	Fix it, transactional, single loop opening to double loop.	How do we help/mutually exploit each other? "It's all about each of us living up to our side of our (implicit or explicit) contract."
Interdependent	Collaborative	Curious, Creative. Double loop inquiry opening to triple loop.	How do we collaboratively envision and manifest something truly creative together?

Case I: From Unilateral (non) Inquiry to Independent Relational Inquiry

Research suggests that in the earliest stages of development women's self-protection is expressed more often as silence (Belenky et al. 2008), while men's is expressed as aggressive, what Cook-Greuter and Torbert (2004) labeled "opportunistic." A self-protective ego renders inquiry invisible and unnecessary to its aims. Key to note from a relational reflexivity lens then is that at the earliest stages of development, there is simply *no inquiry*. In the human sphere this means that there is very little possibility for meeting among people as "subjects," but rather as self-protective objects.

The second author first documents her own journey from self-protective in the context of reflexive developmental inquiry. She then offers an illustration of how reflexivity can become a useful foundation for subsequent work with other stakeholders in the inquiry/practice of transforming how she relates with power.

> **Lara writes**: On my professional journey I have seen that there are ways in which gender plays into particular power dynamics. With women that I admire I can project my disowned (golden) shadow in the forms of embodied confidence and intelligence. While evoking a feeling of admiration, this particular projection can create feelings of competition and distrust, while activating shame. I will contrast an early example with a later one to indicate how this has played out at different times along my developmental journey.

> At the start of my professional life in my mid-twenties, I had a female colleague that I both loved and respected and yet also felt triggered by. I perceived that when we were facilitating together, she tried to outshine me and did not give me as much opportunity to contribute. In response, I would enter a space of silent frustration, either shrinking away into the background or making efforts to assert myself that felt untimely and inauthentic. Aware enough of what I was struggling with, I suggested that we find a way to have a regular debrief together, as I knew that I needed a structure to be able to address and unpack what had come up in our class. However, my colleague never seemed to remember this agreement and, feeling defeated, I never reminded her, much less insisted. Even though I didn't think any of this was necessarily conscious on the part of my colleague, I started to build up resentment. I never overtly addressed the feelings that I was having and it fed into a diminished sense of self. While this dynamic did not present obvious rifts in our relationship, I believe that it affected our synergy on a subtle level and eventually our work together waned. We drifted apart.
>
> I continued to inquire into this dynamic – also present with other colleagues. I saw that one of my primary shame triggers is being perceived as unintelligent, or as if I do not have anything of value to offer. (Isn't life interesting – I have been, in the role of educator, easily exposed to this trigger. We teach what we need to learn!)
>
> Fast forward 10 years, and I find myself co-facilitating with another female colleague and this time working with a group of professional educators, all of whom I had great respect for. At one point one of the student educators voiced a feeling of not being comfortable with some of the group dynamics at a time when I was the lead facilitator. While on an intellectual level I was grateful for this student's feedback, my shame trigger got activated. I was aware of many layers of shame and of being triggered, and my inner dialogue went something like this: "Wow, she just revealed something very important about our container. I see other students responding/reacting to this. I feel heat rising from my solar plexus – shame is here. I feel concern for this student. I have an impulse to try to fix something but also an awareness that things are unfolding in an essential way that does not need to be interrupted. We are a group that can tolerate the heat of discomfort and even benefit from it." Aware of many contributing factors and being kind to myself (after all, what educator has not had negative feedback?), I still felt the discomfort of shame and questioned what I could have done better.
>
> When my co-facilitator found the opportunity to debrief with me, she listened compassionately, mirroring me and sharing her own (more positive) experience of what had happened. Talking through it and sharing the insecurity and shame I was feeling helped me to digest the strong emotional aspects. From here we moved forward in our planning and facilitation from a clear and integrated place. My vulnerability created more trust and strength in our collaboration. We drifted together rather than apart.

Developmental Reflection (both authors reflect together): In the first example, Lara was exercising unilateral power, but in the guise of silent self-protection (which is an inverted form of power at the earliest stage of development). It is unilateral in that neither Lara nor her colleague could dialogue, much less share power. Lara has since realized she had an either/or orientation: If her colleague was shining, she was not. Her strategy was to avoid conflict which prevented learning. As is natural when younger – and a key obstacle to growth if we remain immersed in early action-logics – Lara did not have enough perspective to see her projection. She was subconsciously comparing herself with her colleague, projecting discomfort outward making it mostly about her colleague's behavior.

In continuing over a decade and more in the practice of relational reflexivity, Lara has gained the ability to see herself in action and thus more capacity for relational reflexivity. This perseverance in inquiry, with self and others, is a key developmental move. It brings the capacity to engage with others as human beings (rather than as fantasy objects who are better or worse than the fantasy of the isolated me). We get to see she’s now able, in the moment, to “make object” (we use Kegan’s term for developing awareness of key developmental experiences) both the emotions at play and her own thoughts and feelings in the space between self and other. This is holding me and us together, while embracing single and double loop inquiry, leaning into triple loop. More critical than rational insight is the ability to make space for the ego’s self-protection which is anchored in undiscussable emotions, such as shame. Lara was aware that she felt shame yet was not entirely shut down by the experience. Instead, she was able to have perspective on the somatic sensations of shame and the way that thoughts can “spin” themselves to stay comfortable. This capacity for stepping into discomfort – something that is helped by meditation and self-inquiry practices – allowed Lara to remain rooted in her center and present as a facilitator. Lara moved from repressing what was upsetting her to creating conditions for co-creativity. Shame may be one of the greatest teachers of all, but only if we can turn to it for its wisdom.

Independent Relational Practice: Relational research is first a process of noticing and transforming inner experience. It is the act of applying reflexive practice to oneself. In the developmental reflection above, we see how first-person reflexive practice can be developed to the extent that it is applied in the moment as a way to assess if one is congruent in their stated values, intentions, and actions (Chandler & Torbert 2003). The point of reflexivity is not to decide what’s right and wrong, but to notice the degree of distance and closeness available, by choice, to the one in inquiry. We might say that this accordion capacity is a prerequisite for becoming a practitioner of ARTful developmental inquiry.

Case II: Relational Developmental Inquiry Across Genders.

Interpersonal ART may be defined as the ability to know ourselves in and through relationship, as opposed to personal inquiry, in such a way that degrees of distance and closeness can become more available, by choice, to the ones in explicit inquiry together. From an evolutionary perspective, our conditioning as primates is to remain deeply concerned about remaining part of our troupe. Thus, the relational and gendered aspects of life, experienced up close in work situations for example, can be profoundly anxiety inducing. From a gender perspective we might say the troupe (or today’s workspace) remains insistently patriarchal. The legacy of invisible male domination serves neither women nor men in our increasingly complex, knowledge-based democracies. In this power is taken for granted without being consensually chosen or consciously wielded. It is in this territory that Hilary engaged her mentor. What follows is a relational reflexive inquiry with all the parties involved. The case is excerpted from a longer, published transformative dialogue (Bradbury & Torbert, 2015) which seeks a restorative outcome through mutual exploration between a woman and a man working together in a research context. She as the assistant, he as the research director, in a pattern of power distance that is typical of many modernist institutions.

> **Hilary writes:** I arrived to work one humid summer's day wearing a favorite skirt. Quickly I became aware of how he was not listening to my words but was only noticing the way my skirt had fallen open to reveal my legs. Instead of feeling beautiful in a beautiful skirt, as I had started out on my day, I now felt awkward. I tried to "cover up." I kept my hands on my covered knees as though auditioning for guidance in an Amish community. I had a feeling I had done something wrong but what, I was just not sure.
>
> Another day, soon after, I felt awkward. And, again, I said nothing – this time, as I left our meeting the research leader licked me from the V of my t-shirt along the face to the side of my forehead. A great lick. Yikes. As I disengaged, I was a bit shell shocked. What had just happened. Some 20 years later I returned to invite the research leader, Bill, to talk (and then write together) about what had happened between us. The intention was to restore our capacity to work together with someone I respected but whose behavior confused me. At first, we sought the help of a mutual friend.
>
> **Bill writes:** When we first exchanged our (different!) written stories about our early relationship, we both gave "OUCH" cries by e-mail and Skype, and asked to have a face-to-face talk, including a third person we both trusted to facilitate our listening, our hearing, the clarity of our speaking, and our self-questioning of our own premises. What I did not yet understand, in spite of our writing to one another, were two facts: first, the simple fact of your not being at all physically attracted to me in spite of your ostensibly flirtatious actions; and second, the more complicated fact that my being physically attracted to you, as a minor aspect of my overall attraction and assessment, had made you feel so awkward, unconsciously self-protective and, then, (this refers to a part of the story omitted from this retelling) destructive in our shared classroom.
>
> Gradually, though, I have digested the notion that I tend to develop a generalized crush on some women who, like my mother, I find delightful intellectual companions and conversationalists. In such cases, I presume the generalized erotic attraction between us to naturally include a sexual element, when that aspect may very well be only an aspect of my own "crush," yet whose potential for 'disappearing' the feminine voice, especially when I hold greater institutional power, had not been so apparent to me as it has now become. Or at the least it's all a much more complex experience for a young woman juggling historic powerlessness and newfound freedoms for which she has not received mentorship.
>
> **Hilary responds:** I am deeply touched by this truth speaking between us. You were an older, more powerful man whom I wanted to flatter. At the same time, I deeply desired to be seen by you, without realizing that it was in the eyes of teachers that I could best intuit my own capacities. Now I see my access to power in our relationship originated with a mix of flirtation and self-protection. These interactions were themselves to a large degree shaped by the powerful social structuration of patriarchy in which junior women accommodate senior men. The difficult work of noticing, exploring and changing these norms falls on the one least empowered to change them. This difficulty is exacerbated when I notice that any

> exploration risks embracing a paradox: I don’t want to lose good mentorship/friendship and I do wish to emancipate myself from patriarchal structures while simultaneously protecting you (or any man) from the consequences of your own behavior, which I (and most women) learn because we are socialized in patriarchy. Most difficult then is displacing male discomfort onto a self-forgetting feminine self. This is hard!
>
> The intervening years have allowed me to make an invitation to you, which I believed would land well because of your own deep commitment to self-inquiry. The idea is that both of us might notice and distance ourselves from all-too-common norms of non-inquiry. The invitation is motivated by a growing awareness that men too suffer inside patriarchy. And more importantly, that democracy itself will be enhanced, a bit when women and men work better together. There’s opportunity here for the previously unempowered to learn how to enter into co-creative structures that work better for all. There’s even opportunity here for the previously powerful.

Developmental Reflection: Something innovative, and in this case, restorative happens when two persons can discuss a shared problematic experience. Later stages – supported by the privilege of good education, time to reflect – do not mean that there are no problems, merely that problems are more likely to become mutual, trust-building inquiries about what has happened. It is important to mention, at least as an aside, that there is obviously more to a relational context than can be mentioned in a short case. The simpler narrative of transformation here is that together they made space for relational inquiry. At first it allowed for simply “managing to get along.” Later, building on sage experiments and small successes, it allowed for the eventual and deeper reconciliation sketched here. What had been initially unilateral power gone awry in a dyad was “composted” toward a profound healing experience. And importantly it may illustrate a dialogue practice useful for others stuck in mutual criticism with its implications for co-creating better forms of democracy.

Inter-independent Collaborative Practice: In the case above, we see a move – over a decade – from independent, individualistic to more mutual relational practice as Hilary and Bill dialogue through writing inquiring into the space between them. It interweaves single, double, and triple loop inquiries by necessity. The suffering is followed all the way down to how cultural and biological scripts (flirtation and seduction) must be looked at, made objects of inquiry until more ease is reached together. Transformation begins as they address the deeper values and action-logics that keep problematic gendered behaviors in place in the form of both cultural and personal scripts. The relational reflexivity of both parties together opened an inquiry into increased relational well-being. As a research methodology, such a relational approach between researchers and research participants (stakeholders) generates real-time data about the efficacy of our initiatives while tending to the often hidden and undiscussable conflicts that arise around interest and power (Chandler & Torbert, 2003). In this way, we develop our own escape route from the dungeon of self and community repression, a bit more liberated for creative expression and authentic connection. Benefit redounds to me, us and all of us as deep scripts are liberated from a unilateral stage of unknown, undiscussable to shared inquiry and more relational creativity together.

In the above cases we show the interplay of reflexivity with development through our own reflexive practice on our work as action researchers. Both cases demonstrate how without reflexive awareness, power is experienced as an external force. Enacting unilateral power is commonplace, either in its expression of "say nothing" or mindlessly dominate. Although this power dynamic continues to show up in life, over time it can also be transformed through accessing power-within – a combination of self-regulation (within discomfort) and choice (of how to respond). When dependence and independence become integrated, we can move beyond the power struggle of he said/she said toward a mutual power that holds within its frame the needs and preferences of others (Commons and Ross 2008). Together the cases illustrate an arc from unilateral self-interested power to shared-power-to-do. In sharing them the cycle of learning may be shortened.

We now turn to complete the presentation of a relational transformative methodology with a discussion of validity – our preferred term is quality – appropriate to it.

Assessing Quality with Seven Choice Points

Validity measures in conventional science and inquiry relate only to internal and external validity. And, while that is always relevant in knowledge creation, from the point of view of ART it is rather too narrow a bandwidth of concern. Contemporary qualitative research began to offer new pathways to enrich our notions of what counts as valuable knowledge (e.g., Lather, 2008). These notions, briefly introduced earlier in the paper, have informed the seven choice points which originated with Bradbury and Reason (2000) and have since been developed over the past twenty years for use in evaluating and developing publications and research designs, now codified by the associate editors of the journal *Action Research* in Bradbury et al., (2020). In addition to assessing the quality of work, the choice points themselves serve as a tool to elicit reflexivity. The seven choice points follow, with discussion of their presence in the two cases presented. As "taking action" is a critical part of action research, we also include illustrations of how relational and collaborative practice has emerged from the work described earlier and which serves a next generation of efforts. The following examples expand on the above cases to include collaborative learning initiatives developed from the first author's work within the Action Research Plus (AR+) Foundation and the second author's work within The Artemis School for Women's Sexual Sovereignty.

1. Articulation of purpose and objectives refers to the clarity of purpose with regard to intended knowledge creation through, and for, action in support of our collective thriving on this planet.

In the first and second cases we see a conjoining of knowledge of mind and heart (Belenky et al., 2008) or heart, hand, and reason (Bradbury and Torbert, 2016) that describes a developmental shift in the direction of mutual power. Mutual power implies not only care for our own thriving but for that of our partners and communities.

2. Partnership and participation refers to the extent to and means by which participative values are evident in the relational component of research, on a continuum from consultation with stakeholders to stakeholders as full co-researchers, including multiple ways of knowing-for-action and room for explicit concern for questions of "whose knowledge counts?"

In both cases those involved are both participants and co-creators. The participants develop personal empowerment through the primacy of their first-person inquiry which leads to an expanded worldview alongside a deeper ability to recognize desires and feelings.

3. Contribution to action research theory/practice refers to the extent to which the work builds on, and/or creates explicit links with, and or contributes to a wider body of practice knowledge and or theory, that clearly contributes meaningful new action research knowledge and insights in the action research literature.

The type of relational inquiry described here has since been developed and implemented with others, in collaborative learning programs. The practice, called Relational Action Inquiry Research (RAIR), was developed as a way to teach/learn about how to better transfer the ownership of an inquiry from researcher to stakeholder in the field of action research. As a result, a dedicated program has since been developed by the ActionResearchPlus Foundation to support universities and think tanks who practice action research. One stakeholder-participant reflects, having learned about and begun to use some of the RAIR tools in her own endeavors:

> I realize that in each of the two coLAB cohorts that I have joined, something big has happened for me. Each has led to something quite transformative. For example, my former [work] group has now been dissolved, helped a lot by coLAB conversations, and we are starting a renewed and refreshed artistic/social-justice exploration.

Another reflected also on the cultural diversity of global both and south practitioners working together amid their own power dynamics, a global south practitioner reflects:

> I think that, coming from such diverse places, from such different contexts, naming issues of power and staying in conversation will allow us to complete a puzzle that never ends, but grows and expands. Understanding the role of shared facilitation and our concern for "caring" will allow for much more humane changes, also in policy making. What we learn in this coLAB will, yes or yes, generate a positive change in whatever we set out to do.

Additionally, the second author developed a program called The Artemis School for Women’s Sexual Sovereignty, a year-long practitioner training program for women. The action-oriented curriculum of The Artemis School strove to create a learner-centered and self-actualizing vessel that interwove first-, second-, and third-person inquiry-practice. Issues of power in sexuality education are fraught in a culture that has primarily dealt with sexuality through shame and repression. Therefore, to create an integrative, healing approach to sex education it becomes essential for practitioners to reflexively uncover their own internalized issues of sex and power. That is to say that the work of becoming a sexuality educator requires one’s ongoing development and reflexive participation (as shared in the illustrations above). The transformative nature of The Artemis School’s praxis was anchored in the premise that creative/erotic energy, can be engaged as a sacred, transformative agent. Thus, the curriculum was designed to support what we understood to be pre-requisites for becoming a sexuality educator namely: 1. Inquiring into one’s own sexual shadow and shame, 2. understanding one’s own erotic development as a line of adult development, and 3. embodied practice in a group learning field.

4. Methods and process refers to the extent to which the action research process and related methods are clearly articulated and illustrated "show," and not just "tell," by including analysis of data along with the voices of participants in the research. Knowledge creation includes and transcends rationalist empiricism to acknowledge whole persons as relational beings.

In the illustrations above, journaling, dialogue and reflection, including somatic focusing were the key methods. The participants were empowered to explore with different relational formats, including inviting a third mutual friend to facilitate. In this we can say that classic methods of qualitative research are refreshed in a more relational approach, so that field notes (journaling) and interviews (reflective dialogue) became more deeply interactive and transformative.

The relational pedagogy is practice based. It's successful when ideas are embodied and come alive in practice. For The Artemis School and AR+ Foundation this means intentionally weaving theory with experiential practice such that participant inquiry is deepened, and mirrored through, attention to intersubjectivity. This learning evokes multiple ways of knowing in any subject area. The breadth of ways of knowing can be understood through The Artemis School's general tapestry of practices: Embodiment, Contemplative, Narrative, Expressive, Relational, and Analytic/Dialogic. There is time for silent, contemplation, for example with paint as a way to further metabolize learning (expressive). When comes time to learn about challenges (analytic), each participant's, first-person accounts as well as a socio-cultural backdrop from which to work toward solutions is happening within a holistic/integrative model of knowledge, that some call metamodernist (Andersen, 2017; Rowson and Pascal, 2021).

5. Actionability refers to the extent to which the action research conveyed through the paper provides new ideas clear enough to guide action in response to need.

Participants in all cases developed experiments that enriched their own professional context from which there is a ripple out effect both formal (as publications and workshops) and informal. For example, a stakeholder-practitioner of The Artemis School delivered her learning in a program for youth:

> It's affected my teaching. For example, when I spoke to an intimate group of high school-aged females, I spoke with more authority and lived experience about body autonomy, knowing our anatomy, and claiming what is ours. This led to a discussion about why this is important and the implications of this in our current society. It felt like I could speak to it from a place of body knowing rather than mental knowing.

6. Reflexivity refers to the extent to which self-location is acknowledged. By self-location we mean that authors take a personal, involved, and self-critical stance as reflected in clarity about their role in the action research process, clarity about the context in which the research takes place, and clarity about what led to their involvement in this research. That the knowledge creation integrates personal/reflexive, interpersonal/relational and impersonal knowledge, thereby growing those involved and empowering participants in social change to shape the world of their aspirations.

While other ART might highlight different choice points, reflexivity is an especially key choice point in the cases presented. Two of its signatures are turning to power dynamics and making self-discovery a prerequisite. Power, in the form of ‘power-within,’ then becomes available as a conscious choice in the pursuit of a more embodied, developmental path which includes deeper shadow work and radical self-responsibility for enacting ‘power-with’.

As noted above, self-discovery involves shadow work, i.e., making not quite conscious aspects of the self, more explicit and seeing how they are culturally shaped not so personal at all. When brought to conscious awareness, what one fears or denies, may become available and integrated with our intentions. We thereby embody clearer expressions of thinking and action – albeit likely with hiccups along the way, which provide more grist for learning.

In the second case above we see how initial reflection on the past by Hilary and Bill could become an ongoing, emergent, reflexive relationship as each party reflects then intentionally practices a more generous way of relating. Reflexivity spurs development of the individuals, the relationship, and in the work that each do individually.

7. Significance refers to the extent to which the insights are significant in content and process. By significant content we mean having meaning and relevance beyond their immediate context in support of the flourishing of persons, communities, and the wider ecology (i.e., generates both local and public knowledge). By process we mean involvement of stakeholders through strategies and methods that connect people and knowledges in ways that help them develop a strong and authentic sense of development and evolution in their practices, their understandings of their practices, and the transformation of the situations in which they practice.

This may be best expressed not through the authors but the voice of a representative stakeholder to show rather than tell what significance was experienced. Artemis school participant, Delia, shares how her learning wove between herself, interpersonal relationships, and the culture of her work:

> I developed the ability to talk about myself and the inner working of my mind/body and the world using real language that resonated. I was able to help others find this language for themselves and feel heard/seen . . . I was also able to hone the capability of holding space for others as a facilitator and mentor, which has positively impacted my professional and personal life.

Limitations

ARTful inquiry, as with any scientific and knowledge creating endeavor, concerns learning from and improving upon one’s experiments. Rather than providing a definitive expert answer to a manifest problem, action research as ART outlines a path of inquiry that connects outward work with inner work. ART also provides seven quality choice points by which to assess and reshape the value of the inquiry.

As action researchers for transformation (ARTists), we aim to work at our developmental edge and to discover what might be possible in our development together. In addition to highlighting what is experienced by participants as valuable, these cases may also reveal what does not work or, at least, what can be improved upon in a next cycle of inquiry. From a conventional scientific standpoint, we recognize that replication or generalizations are not easy. But that is not the point of ART. The process is to be replicated, which means it will look different. An ongoing inquiry, and challenge, is how we might work more effectively across developmental difference to support every stakeholder to engage at their own developmental edge. Facilitating a context that is safe enough to allow discomfort is key and worth of its own lengthy treatise. We learn here that while development can be scaffolded, it cannot be forced. Development is a process with its own timing. Within a workshop setting participants might receive a conceptual map to help start the inquiry but the actual shift in action-logic may occur later after much personal experimentation. For this we need more learning spaces with sophistication about facilitation. This is not to suggest that relational action inquiry sometimes fails to go far enough and that some participants may become mired in reactivity (Bradbury, 2021), but that we work with an assumption – checked and reaffirmed – that consensual agreement is better than violent disagreement; and that mutual power-with creates more generative outcomes than unilateral power-over.

We recognize that we have offered a primarily binary formulation (unilateral egotistical versus relational collaborative) that deserves nuance. Here the work of Frimer and Walker’s (2009) account of the development of moral character may help. They suggest a three-step sequence in which (1) early in development, in different contexts, children can be either self-interested or concerned with others; (2) over time, self-interest comes into conflict with concern for others; over time, the individual’s moral self can develop in the direction of self-interest, concern for others, or it can undergo a transformation in which (c) self-interest and concern for other are coordinated and reconciled – I make it part of my interest to be concerned for you. The point here is at the early levels, the child is not entirely self-interested in the sense that there is access to (separate) care for others. One might suggest that something similar goes on in the development of power relations. One might seek dominance and power in some contexts but act out of care in others. Such a notion however complexifies the developmental model of power relations. We are pointing to the type of power that is problematic, especially when practiced well beyond childhood. Nonetheless this nuance allows us to know that we have innate capacity from the start, which can be developed. And there is always a need to continue the inquiry.

We keep with a broadminded vision of science as an inquiring temperament animated by an appetite for self-correction and, personal development. As such we hope that the selected interactions will be useful, or at least not too scary, for others’ experiments in reflexivity and awareness of power relations. We even hope that the quoted material might have applicability beyond us. We have offered not a formula but a spirit of inquiry and some brushstrokes for how to proceed. The interested reader might consider their own engagement in the ageless work of cooperation, thus moving from a self-centered (either/or) worldview to a relational and, eventually, collaborative (both/and) worldview of relationship with others.

Conclusion: Developmental Relational Inquiry in Practicing as ARTists

We have illustrated a methodology that responds to the increasing complexity of our postmodern world without being mired in deconstructive criticism. It offers a way to listen in new and exciting ways to self (as inquirer) and other (the stakeholders or co-researchers). In this period of postmodern inquiry, there is now a proliferation of qualitative (Denzin and Lincoln, 2018), and participative methods (Burns et al., 2021). Not all such approaches to methodology share the pragmatists' concern with making the world better; not all enable collaborative action as does participative action research. Our choice of methodology is determined by the purpose of the work. In this case namely a commitment to share/transfer an inquiry so as to liberate new lived praxis among stakeholders, i.e., using methods that engage increasing choice and flexibility in responsiveness to the call of the times; to (re)make the relational world with one another.

Our relational methodology does not conform to the requirements of the Scientific Method, whose power aims to describe not change reality. Our work is in the tradition of Pragmatism (Dewey, 1929; Addams, [1902] 2002, Habermas, 1987), informed by social construction (Berger and Luckman, 1968; Gergen, 2015) and standing on the shoulders of action researchers (Lewin, 1947; Bradbury and associates 2015; 2019). Action researching brings dynamism to the task of knowledge creation because we work with the *dialectical, or back and forth, movement between* 1) individual change agents and stakeholders needs; 2) personal experience and concepts; 3) experiment and reflection, and 4) external world with the internal world of the learners' emotions and intentions. This "both/and" dialectical learning scaffolds developmental growth for those involved. It invites us beyond the autonomous expert mind of "yes *or* no" thinking (what current school systems are designed to produce) to redefining; an embrace of complexity to collaboratively produce (*yes and*) a world worthy of our aspirations.

The power of action research transformations stems from its ability to bring the best of scientific temperament – a concern with self-correction and reflexivity – to intersubjective dialogue (and other sensemaking processes involving multiple perspectives). Its goal is creating and leveraging conditions for dialogue that increase consensual action for the collective good. We believe that the work can be replicated, albeit in different circumstances and with different actors, informed by the experiments illustrated above.

ARTists can transformatively grapple with the issues of power that keep the current unsustainable system in place. We have illustrated power dynamics among and between gender. The same dynamics are applicable when looking at power in ostensibly different contexts, e.g., in executive powers exercised in a democracy or within a household. Importantly, we suggest, the power between humans and the greater than human world of flora and fauna is also relevant. The latter is a world granted no power (with notable exceptions, such as in new laws of Ecuador and New Zealand that grant rights to nonhuman living systems such as rivers).

Regardless of where it's exercised, practicing consciously with mutually transforming power involves a shift from zero inquiry unilaterality to collaborative creativity. The good news, even for an anxious ego, is that there is even more power (as collective empowerment) beyond unenlightened self-interest, beyond tribalism and specism. It's a power that manifests the intention of co-creating a more beautiful world. It works by involving key stakeholders in linking our personal and interpersonal development to realize our intentions. As action researching ARTists, then, this kind of personal and interpersonal practice allows for development in inquiry so that transformation through big and small experiments can replace the structures that impede our better aspirations. Truth joins hands and hearts with beauty and goodness.

We find that few scholars practice with transparency around issues of reflexivity, beyond offering a litany of identities that labels the self who inquires. Knowing the labels does not, in itself, usher in transformative inquiry. In ART reflexivity is cultivated as a developmental praxis– helping to clarify where scholars/ARTists are with regard to our developmental reflexive edge. Knowledge co-created with stakeholders invites room at the table for other, typically silenced or marginalized, voices. Through our case studies we introduced how this kind of transformative, developmental praxis can support us in re-imagining relationships and social systems that hinge on unilateral power. Specifically, we suggest that ART offers a pathway forward for cultural creatives that is anchored in our day-to-day lived experiences (action) and forms a future with a new kind of relating and logic of power between us. An action orientation to knowledge creation, therefore, has major implications for how education and scholarship could be structured, and how communities learn together, whether about power or climate change, or within universities, or places of work. It echoes Kant's Enlightenment call to "sapere aude" ("dare to know") and beckons a reweaving of humanities and natural sciences, on a journey that integrates development of self, relationship, and community.

The Many Faces of JEDI:
A Developmental Exploration

Aftab Erfan[1]

Abstract: Many organizations and communities have grown initiatives dedicated to advancing justice, equity, diversity and inclusion (JEDI) at a time when global and local inequities are front and center in the societal discourse. The movement towards JEDI is simultaneously full of positive transformative potential, and full of both ideological and interpersonal conflict. This paper explores the JEDI movement in organizational contexts using a developmental lens. It applies the structure of seven action-logics from adult development theory to describe how one's orientation to JEDI issues may mature over time. It offers suggestions for how late action-logic actors can become more effective in the JEDI space by recognizing the dynamics at play and intentionally supporting and expediting vertical development of the actors involved.

Introduction

A graduate student I work with has been painstakingly organizing a training on anti-Black racism for their entire department. The night before the training, the departmental director drops a casual note to say that they are tied up with some deadlines and cannot attend after all. The graduate student is rather upset, having counted on the director's presence to legitimize the investment of everyone's time to learn, and to communicate that this topic is everyone's business. The next day the graduate student sends a note to the director, expressing understanding of the circumstances and a hint of disappointment. "I wonder what we can do about our departmental culture where deadlines always feel more important than learning in community?" the note asks. The director writes back defensively and at some length, listing all the books they have read on anti-Black racism, mentioning that their best friend growing up was Black. "I'm already woke and didn't need the training", is the subtext. The student comes to me for advice, baffled by the response. How could the director be making this about *them*?

SOME RIGHTS RESERVED

I have often observed this kind of phenomenon while working in organizations on issues of justice, equity, diversity and inclusion (summarized by the acronym JEDI[2]). So often it feels like people are ships passing each other in the night, ostensibly in the same conversation but actually talking about different things. In this case, the graduate student sees the need for the community to be learning together on JEDI topics, and takes issue with an outcome-driven system where meeting deadlines always trumps being in process together (Jones & Okun, 2004). The director is rather oblivious to the larger departmental system or their impact on it. They think they have made an individual choice about an individual learning opportunity. This disconnect is echoed in much of the discourse over systemic racism – a term that found currency over the summer of 2020 in unprecedented ways – where people in our systems (education, health, policing) took offense to the allegations of systemic racism. "But there is not a racist bone in my body" was a common sentiment (to which Vicky Mochama (as cited in Cole, 2020, p.34) clapped back on Twitter: "Maybe racism is a skin condition"). Radley Balko (2020), writing in the Washington Post, observed that

> systemic racism [is] often wrongly interpreted as an accusation that everyone in the system is racist. In fact, systemic racism means almost the opposite. It means that we have systems and institutions that produce racially disparate outcomes, regardless of the intentions of the people who work within them.

The confusion between systemic and individual impacts could be at play in the example of the director and graduate student. While it could be explained away as a misunderstanding, I tend to think that their disconnect runs deeper and has to do with the breadth, depth and complexity of their meaning making and subsequent engagement with the world. Since I have been exposed to the theories of adult development, I can't help but think that there is a difference between the director and the graduate student in terms of their action-logics – that is, the way they each interpret their surroundings and react when their power or safety is challenged (Rooke & Torbert, 2005). In this paper, I wonder out loud: what if our orientation to JEDI topics is coloured, not only by our politics and ideologies, but also by our stages of development? I write out of a hunch that seeing the JEDI space through a developmental lens may benefit our ability to make sense of our interactions within this space and on its peripheries.

My Own Location

I explore these topics as a scholar-practitioner who has been immersed in JEDI over the last decade. I spent much of my twenties in environmental and social justice movement spaces, then played institutional JEDI leadership roles at a large university and a major city government. I have consulted at several other institutions. I'm writing primarily based on my engagement with the JEDI discourse in Canada, which is closely linked to the discourse in the United States, and may also have global resonance to some extent. As well, I write as a first generation immigrant from the Middle East, Muslim by birth, settler on Coast Salish lands. I identify as queer and as a woman of colour. I also carry a ton of privilege, including that of a PhD. I have a sense of belonging to the social justice movement. My professional roles have also taken me to the edges and outside of the bubble of JEDI advocates. I have acted at times as a mediator and bridge-builder with folks who are explicitly opposed to a social justice agenda, and have therefore got a view of the movement from outside. In short, the challenges of dealing with difference, power, and inequity are *my* challenges – important to me personally and professionally – and I write in pursuit of transformation towards a more just world.

---

[2] Some groups and organizations use the JEDI acronym where the letter D stands for decolonization.

I write also from the edges of the adult development community where I have many connections and have been both a skeptic and an observing participant in its communities of inquiry. What I present here is not based on an empirical study, but rather draws on my understanding of the action-logics as articulated by leadership scholar Bill Torbert. Over the years, Bill and I have mapped the development of the notions of power (Erfan & Torbert 2015), inquiry and mistakes (Torbert & Erfan, 2020) at various action-logics.[3] The current exploration of orientation to JEDI at each action-logic arises from a conversation with Bill, for which I am very grateful. I am additionally influenced by the pioneering work of Dr. R. Roosevelt Thomas, and by scholars Toni Gregory and Michael Raffanti who devoted much of their careers to growing the conversation on social justice beyond identity politics. In the late 1990s and early 2000s, they wrote on "diversity maturity" and offered some sketches of a developmental path towards it. While I am alert to the pitfalls of developmental thinking (see below) I find myself helped by the mapping projects that these scholars have undertaken. Their maps orient me and compel me to choose the version of myself that shows up for every interaction. At times they offer protection against simply being snatched by my fear responses, or by the dominant mindset of the environments or groups I find myself in. As I engage in this form of mapping below, I do so with a hope that it is similarly helpful to my colleagues in the JEDI movement.

Introduction to Adult Development

At the core of adult development theory is the idea that true grownups are rather rare. Most of us adults live in the constant possibility of growing up, and could make major cognitive, psychological, behavioural and spiritual step-changes in our adulthood as we do in our childhood. The basic idea is as old as the wisdom traditions, such as the work of the 12th century Sufi poet Attar of Nishapur, who articulated the path of the soul in a seven-stage spiritual journey. A secular variation of such a path has been researched and theorized by modern day psychologist and leadership scholars, and supported by advancements in the field of adult neurogenesis which documents appearance of new neurons in the adult brain. Adult development theory states that we can trace a line of development between an individual's younger and older self, which goes through somewhat predictable territory with several plateaus. Several methodologies exist for estimating these plateaus (also known as action-logics) at any given time for any given individual.[4] Like leveling up in a video game, each action-logic gives us new powers, new capacities to deal with complexity: not just new skills and tools (like a new weapon) but new mindsets and paradigms (like the ability to see the game in three dimensions, rewrite the plot, or change the definition of winning). Research has shown that leaders at later action-logics are more effective in complex organizational contexts. Subsequently, adult development theory, while acknowledging the gifts of each action-logic and its appropriateness in the right context, generally has a normative bias towards vertical development, which is to say that it advocates in favour of growth towards the later action-logics especially for those who aspire to higher leadership roles.[5]

---

[3] For a full exploration of a developmental trajectory spanning the action logics through a lifetime, see Bill Torbert's 2021 autobiographical exploration, *Numbskull in the Theater of Inquiry: Transforming Self, Friends, Organizations, and Social Science*

[4] See, for example, the Global Leadership Profile https://www.gla.global/the-glp-overview/

I pause here to acknowledge that adult development theory can be prone to elitism and exceptionalism, with its privileging of "more developed" ways of being, which could fly in the face of the basic JEDI commitment to equalizing. I have long been alive to this fear. At times I have indeed found the adult development field elitist: too focused on the top tiers of corporate entities, and less concerned with the pursuit of societal goals like justice. On a personal level, I have also witnessed developmental ideas weaponized and used in oppressive ways, sometimes by supposedly "developed" people to put others down or create separation between an "us" and a "them". But more often I have experienced adult development ideas as status-quo challenging and liberatory. I have seen these ideas trouble hierarchies, patterns of domination and authoritarian uses of power. Importantly, developmental theory points to the shortcomings of unilateral power exercised by earlier action-logics, and advocates for development of a capacity to exercise mutual power, characteristic of later action-logics. Mutual forms of power have an orientation towards integrity, generosity, reciprocity, and the collective – which are well aligned with JEDI goals.

In organizational settings, a developmental analysis often turns our ideas of power and hierarchy upside down. It exposes, for example, the inefficacy and shortsightedness of the archetypal strongman leader who may be sitting at the helm. It daylights too, the key role – and key struggles – of informal leaders. In the case of the graduate student and the director introduced above, a developmental lens would illuminate that the person with the lower organization rank (the student) has the higher developmental rank. The student is seeing complexity, cultural and systemic patterns that the director doesn't see. This is not uncommon. Your boss, teacher, or parent can well be acting from an action-logic you have transcended. This can make for a frustrating situation, but an awareness of their relative developmental rank can help the later action-logic actor bring the kind of patience and respect to their interaction with the earlier action-logic actor that one might bring into dealings with a younger sibling. It's not that the director "doesn't get it" because they are apathetic or not as smart or as well-read. It is that they don't get it in the same way the student does, because they are elsewhere *developmentally*.

Development is not necessarily correlated with education (so many PhD holders are relatively early in their development, stuck at the Expert action-logic) or with conventional success (average CEOs rank only one step ahead of the PhDs, at the Achiever action-logic). On the other hand, going through adversity, including, for example, experiences of migration, ostracization, poverty, war, illness, or death of a loved one, can grow a person psychologically and spiritually and expedite vertical development.[6] Many Black, Indigenous, refugee, disabled, trans and queer folks I know are among the most alert to the nuances of a situation, moment-by-moment unfolding of group dynamics, presence of multiple conflicting perspectives and visions, the influence of the rules of the game and their arbitrariness, and access to creative problem-solving and bold alternatives. They come by their later action-logic honestly. They have not gone to leadership development programs or personal development retreats. But they possess self-knowledge, systems knowledge, and a capacity for what the Mi'kmaq call "two-eyed seeing" (Bartlett et al., 2012), which comes from a daily need to survive in contexts where one doesn't quite fit in. They possess what feminists have called epistemic advantage (Narayan, 2004). Since they are not shielded by the privilege of living in a world that is made in their own image, they need to integrate, negotiate, adapt, reject, or protect on a regular basis. They experience a level of complexity in daily life that necessitates more complex ways of sense-making and action, which they have no choice but to grow in order to get by.

---

[5] There are some excellent primers on adult development theory that reference the relevant research and current state of knowledge and theorizing in this area. See, for example Petrie (2020).

[6] This is by no means always the case. The literature on post-traumatic growth points to the tremendous role of context in determining whether we grow or shrink as a result of adversity. Understandably, some of us become closed off, guarded and simplistic in our meaning making in response to oppression, especially if we lack familial, community or professional support to process and recover from psychological hardship.

In making these claims I have no intention of glorifying oppression or justifying inequity by reference to its positive developmental side effects. But part of the reason that the JEDI movement is exciting to me is that it recognizes the enormous gifts of the margins and the outsiders, and has the potential of lifting into positions of power, historically[7] marginalized people whose lived experiences have actually prepared them to be the post-conventional leaders we need in this moment. As such there is alignment between the JEDI movement and the imperatives of vertical development. As a more fundamental level, the two also share a commitment to creating the conditions for human flourishing for all.

The Action-logics

Different schools of adult development theory describe the stages of development in somewhat different ways. Here, in its most condensed form, is Torbert's articulation of the seven action-logics (as cited in Petrie, 2020).

1. Opportunist – Deeply concerned with their own needs. Tries to win any way possible.
2. Diplomat – Focuses on conforming with the rules and norms of the organization or peers.
3. Expert – Motivated to gain mastery and expertise. Values logic and respects other experts.
4. Achiever – Driven by goals, achievement, and meeting the standards they have set for themselves.
5. Redefining – Inspired by meaning and purpose. Challenges the status quo to find new ways.
6. Transforming – Generates organizational and personal transformations. Sees the system they are in.
7. Alchemist– Leads with fluidity, seeing the interdependent nature of things. Integrates wisdom and a global conscience.

The action-logics are often portrayed as steps, ascending towards Alchemist. Unlike various classifications of personality types (e.g., Myers Briggs), the basic notion here is not that one belongs in a certain category, more or less stable across one's lifetime, but rather that one moves up the steps, traversing potentially all of the action-logics in a lifetime. The linear path is, of course, a simplification of the growth process itself. In reality, the steps are not orderly or evenly distributed – one could live at an action-logic for decades (think Donald Trump, a septuagenarian Opportunist), or grow through multiple action-logics – maybe even skip one or two - over a short period of time (think Greta Thunberg, possibly a teenage Alchemist). Additionally, one's growth may be uneven across various dimensions of life (think Pablo Picasso, Transforming as an artist, and an Opportunist in relation to the women in his life) so that each person is traversing multiple overlapping, in-synch and out-of-synch strands of development. Familiarity, substantive knowledge and practical skill in each dimension clearly impact the strand (so that if you are just picking up a basketball, you are likely focused on mastering Opportunist on the basketball court, even though you are functioning at Achiever in your day job as a lawyer --- and the fact that you are an Alchemist in the spiritual realm does not prevent you from struggling to become Expert when it comes to JEDI issues). I imagine these strands as multiple stems of beans growing together, distinguishable from each other, and each providing scaffolding for the next (which is to say that, eventually, you can leverage your capacity as Achiever in the court of justice to upgrade your basketball game). To the degree that we can categorize a person at a stage, we may do so by estimating their center of gravity action-logic, a kind of weighted average of their stage of development across multiple dimensions at a specific time. This is what the developmental instruments measure, usually through an in-depth questionnaire to sentence completion exercise.

---

[7] By "historic" I mean since the early days of colonization in this context, recognizing the term is problematic since history existed long before colonization.

Figure 1: Dimensions of development are distinct from each other and provide scaffolding for one another like bean stems.

Figure 2: Levels of development are like rings on a tree trunk, each later action-logic expanding beyond and encompassing the earlier action-logics.

Another depiction of the action-logics is as growth rings on a tree trunk, with Opportunist at the center and Alchemist on the outer edge. This metaphor suggests that each action-logic is more expansive and inclusive of the action-logics that come before it. This means that a person who has developed into the post-conventional action-logics (Redefining or later) has access to the capacities available to someone at a conventional action-logic (Achiever or earlier), but not the other way around. We can build the skill to exercise range: the ability to draw on the capacities of multiple action-logics, based on what is needed in the moment or who we are dealing with. It has been suggested that the ability to exercise range is perhaps even more important to effectiveness than one's stage of development (Petrie, 2020). By the time one arrives as Alchemist, the courageous and wise integration of earlier action-logics is perhaps *the* defining competency.

To complicate things, the description of linear or radial progression through the action-logics is challenged by the fact that people also have a tendency for "fallback" into earlier action-logics when they are triggered or under stress (Livesay, 2015). Many of us have a favourite or habitual fallback. For example, we can function as Achiever but become a super Diplomat, trying to please everyone, when we are not at our best. The difference between falling back and consciously exercising an earlier action-logic can be invisible to observers (if my typically trusting team leader suddenly pressures me to do thing her way, I may not know if she is *choosing* her Expert or *falling* into it) but an intentional exercise of an early action-logic can save a situation which a fallback into an early action-logic can break.

It has been said of the future that it is already here, it is just not very evenly distributed (Gibson, 1993). I feel similarly about the past. And I feel this way about the action-logics: they are already here, available to each of us. Those we have already spent a lot of time visiting are more available to us than those we haven't yet unlocked. I imagine the latter lying dormant under the waters of the collective consciousness – sometimes we have access to them only momentarily, intuitively or through the body. Though we have a center of gravity action-logic, each of us may find ourselves thinking, feeling, behaving and meaning-making from the archetype of the others in different circumstances. Below, as I explore attitudes towards JEDI issues at each action-logic, I write in the first person to illustrate this fluidity. This exploration is not autobiographical per se- my actual examples are often inspired by observation of the archetypes in others around me - but the first-person voice feels appropriate because I recognize myself in all the action-logics. I write in this way as a way of minimizing mine and the field's tendency towards hubris, to reduce judgement, and with the hope that you the reader can see yourself reflected in multiple action-logics as well.

Opportunist

As Opportunist, I am intently focused on myself, my lot in life and my attempts to "win" in concrete ways: money, sex, cubicle by the window. I value freedom and generally dislike rules, especially rules that tell me not to joke or swear or say certain things because I can be offensive to other people. I like to be clever. Getting away with breaking the rules is both legitimate and satisfying to me, and I look up to people who do this well. Simultaneously I support punishment for the cheaters who get caught, especially if they are not me. A concern for equity or justice, in the sense of righting the wrongs of the past, is almost nonsensical to me because I have a very limited historical view. I feel that what happens to us in life is more or less random, people get ahead by luck and by the virtue of their street smarts. Yes, there are the "less fortunate," but that doesn't feel like something that needs to be corrected. Social hierarchy is natural and good. I'm good with pyramids – especially if I am located towards the top.

My support for the equal opportunity programs that claim they are leveling the playing field depends on whether they will benefit me or not. If I fall into one of the identity categories that will get ahead because of the program, then I am all for it. In fact, I deserve such a program. I'll check the "Indigenous" box on the application form if I think I can get away with the claim that my great great grandmother was Native American, and I will lean into my minority race/gender/disability/sexual orientation if that can give me a leg up. If I happen to be an unmistakably straight, white, able-bodied man (or, say, a cisgender lesbian in a queer context where trans women are being prioritized), then I am opposed to these programs. They are unfair and tyrannical, too much like social engineering. I might be compelled to march on the street protesting them. You want me to sit down and talk with people who promote these ideas? Talking with the enemy is a waste of time and a sign of weakness. I am in the right! I'll call the lawyers, the police, or take this into my own hands. If I sound full of double standards, that is because you don't need to be principled when your primary motivation is your own ascent.

Diplomat

As Diplomat I have come to realize that my agenda to do well for myself is better served by getting along with other people. So I shift my focus from "winning" to "fitting in." I become keenly aware of the social norms and protocols in my peer circles, and I do everything I can to conform. JEDI is fashionable right now? I'll be all about it! I will look for and comply with the explicit rules *and* the unwritten ones. I'll memorize the right things to say to be politically correct, not because I think they are right in an objective sense, but because I would hate to upset anybody. I am politically correct in the truest sense of the word. I am the master of virtue signaling on social media. I'll take down the selfies of my privileged self next to children in a remote African village, and replace with selfies of me at the bookstore buying antiracist titles, because that's fashionable now.

Much like Opportunist, I don't have principles of my own. I am told I flip flop a lot, but that's because I am trying to make everyone happy. I'm friendly and agreeable to anyone I happen to be with at the moment. If I am among people who think the political correctness of our times is bogus, I'll likely go along with that too. I won't challenge my sexist co-worker, or my bigoted uncle at the family dinner. I will sit and nod and laugh at the jokes because harmony feels good.

If I can confide in you for a moment, I will tell you that these times of political polarization around diversity issues have been really hard on me. I feel torn and confused when I go from one environment or group to another. The different groups at my work don't get along with each other and I hate that. I hate conflict. First I try to fit in with all of the groups, but when they find out that I am playing all sides they will shred me to pieces. To make my life less complicated, I try to retreat into a bubble of people who are just like me. I hang out in cliques, have a whisper circle, or join affinity groups. But even this is little protection. My in-group shreds me to pieces sometimes because I am not totally up on what we are supposed to say now, and I accidentally said "blind spot", not realizing I was being ableist. I worry that I am not "Black enough" or "queer enough" or "leaderly enough". In order to belong, I participate in outing and shunning other people who say or do the wrong thing. I jump on the bandwagon because the bandwagon feels like the safest place to be. But I live in constant fear of being disposed of by my in-group.

Expert

Tired of the emotional mess of living as Diplomat, I advance myself to the land of objectivity. Here, in the Expert mindset, I am no longer at the whim of the different groups and what they feel is the right thing. Instead I rely on policies that are created and implemented by professionals, and use them as the arbitrator of social relations. The human rights code is a favourite of mine. It defines discrimination, the legitimate grounds for a violation, and it comes with a clear set of operational steps to follow when there is a complaint. At my workplace, we bring in trained and accredited professionals – lawyer, mediators, consultants – to settle a conflict with objectivity and reference to policy. They determine who is right and who needs to be corrected or punished.

To me, the conversation about justice, equity and inclusion has to be rooted in policy. The impetus for organizations to pay attention to these issues is compliance with government regulations, and the impetus for employee to pay attention to these issues is compliance with organizational rules. The rules are our problem solving tools. Everyone needs to be trained on them on their first day on the job. Training, training, training. Then, if people have a problem with each other they would know how to bring forward a complaint so that it can be dealt with fairly and efficiently, without gossip, and under conditions of confidentiality. The more our processes depersonalize conflicts and objectify the problem, the more comfortable I feel.

As Expert, I also have an immense interest in research and data. Everything should be evidence-based including diversity and inclusion efforts. Census, surveys, numbers tracked on dashboards, and solid evaluation data to show program effectiveness are crucial so that our efforts have credibility. If representational data tells me that diversity is not a problem, I will believe it. I generally don’t question the validity of the scientific method and believe that inquiry is objective if based on good technical practices. If I am a credentialed expert like a professor, I am also aware of the power of theory and will put out material to help settle some of these issues. It could be critical race theory I write about, or it could be eugenics. As long as there is evidence, it is valid science and my right to talk about it is protected by academic freedom. The suggestion that my research questions or conclusions are driven by my politics is ludicrous and you would know it if only you cared about evidence as much as I do.

Achiever

Not unlike Opportunist, as Achiever my attention is on success, but I have the advantage of the interpersonal skills of Diplomat and the technical skills of Expert to succeed with. Here, I want to win by the rules – more or less. I’m interested in more abstract forms of success like recognition and legacy, and often I want to expand the sense of achievement to a team or organization. My sense of myself is as an initiator and agent, not a pawn in the system, so much so that I am in denial of the weight of social barriers on myself or others. Although I look to society for values and definitions of success I am able to choose my direction for myself. Will my happiness consist of getting the top marks in the class or of snatching the handsome guy sitting in the third row? Will I move to New York to become a famous artist or stay in my small town and triple the size of the family business? The choice is mine.

In many ways, the world of the past 50 years has been constructed in the image of my ambitions. I live and breathe the American Dream (even if I live in Canada) and hold dear the meritocratic ideas that animate it. I believe that one falls or flies as a result of their own effort, so I take credit for my successes and feel responsible when I fail. If I am an immigrant or an outsider of some sort, I get really good at survival skills (Nieto & Boyer, 2006) and I work so hard that I sometimes perform the dominant culture even better than the people of the dominant culture. I have sympathy for the less fortunate. I give to charity if I have the means, and I believe in the possibility of people pulling themselves up by their boot straps. I am President Obama, telling Black kids to go to college because everyone knows that an education is the key to the dignified life, and if these kids could only believe that they are as good as anyone else they could make it too (Sandel, 2020).

As Achiever in an organization, I am conscientious and self-aware, attuned to feedback about my behaviour and happy to apologize if I offend someone. I go on retreats and work on myself. In the inside pocket of my suit jacket I carry some inspirational quotes: "The success of an intervention depends on the interior condition of the intervener." (O'Brien, n.d.), "If you are not aware of how you are part of the problem, you can't be part of the solution." (Torbert, n.d.), and "Do the best you can until you know better. Then when you know better, do better." (Angelou, n.d.).

I choose an orientation towards JEDI that understands and frames it as a positive, benefiting both individuals and the bottom line. I am excited by the studies on how diverse teams make an organization more innovative and effective. I make presentations on the return on investment of inclusion measures to the board (Douglas, 2020), and I am motivated by being able to say "we're a leader in inclusion". I believe that justice can both feel good and be good for business, and I'm mostly interested in the kind of justice that *is* good for business. I want to decolonize bigger, better, faster (never mind that bigger, better, faster are colonial adjectives – I don't get the irony) and I use a change management framework to do it right. My team gets trained in conflict resolution skills, communication strategies, and gratitude practices. We process group dynamics in meetings and believe that everything, including major wrong-doings like sexual abuse, can be worked through if we talk about them the right way and for long enough. We have self-generated group agreements, and will rely on them first, avoiding the laws and formal policies if we can. Ninety-nine percent of the time, whatever happened was just a misunderstanding. We actively build a positive, collaborative culture where differences are valued – but it is our commonalities we emphasize. Our diversity trainings begin and end with "at the end of the day, we all want the same things." We are all one.

Redefining

"Can the Achiever *be* any more misguided!?" I wonder in my bourgeoning Redefining voice. I watch how the independent, meritocratic, capitalist, neo-liberal Achiever mindset has created the world we live in, and I enumerate the costs. I point to environmental damage, exacerbations of inequalities and widening class and racial gaps, despite promises of "we're all one" and "opportunity for all". How could we pretend we are all in this together, when the differences are so stark? How can we pretend our diversity initiatives are working when it is evident that they only really benefit White women (Smith, 2018)? As Redefining I am at the centre of a massive social reactions to what feels, to many, like the American Lie. I am the social justice warrior.[8]

My thinking is rooted in a postmodern view of the world: knowledge, truth, and morality exist in relation to culture, society, and historical context, and are not absolute. I am alive to and appreciative of difference. I am fascinated by the cultures of others, and possibly by the cultures of my own people whom I left behind while I was assimilating (Nieto & Boyer, 2006). I have become aware of my identities – particularly my marginalized identities- and feel resentful of the ways society has scripted them for me. I may subscribe to an "aggressive victimology" (Cyril as cited in brown, 2021), while simultaneously rejecting the label of "victim". I see the waters I have been swimming in. I pick up a power analysis that is focused on systems of oppression. When I look at inequities around me, I don't see personal gains and failures generated by luck or merit, rather, I see systems – sinister systems, rigged systems – with rules constructed by the powerful to produce and maintain inequalities. I see the forces of oppression everywhere, from the design of segregated schools and restrictive covenants that shaped our cities, to the construction of "professionalism" in organizational cultures: the expectation to show up on time and put in eight hours, to use polite language in meetings and leave the emotions out of the workplace are all ways of ensuring those in power are comfortable, so they can maintain social and economic control (Jones & Okun, 2004). I passionately recite historians and critical scholars who have written on colonization, slavery, white supremacy, and patriarchy. I despise everything that smells like the status-quo. The Achiever capitalist outlook on JEDI as "good for business" is repulsive to me. Justice is essential for our dignity as human-beings and it is distasteful to frame it otherwise.

Paradoxically, my thinking is characterized both by a humble awareness that all worldviews are constructed and therefore relative, and, by a clarity and certainty about *this* truth to the point of righteousness. My truth is subjective (I get that) but much like Expert I am confident that I have answers. Meanwhile, like Achiever, I feel agency to act. I am full of creative vision and conviction. I dream up and implement new institutional arrangements that upend traditional power dynamics (like the Youth Council that is in charge of making the final decisions on the adult-designed programs). There is a certain amount of chaos and excitement surrounding everything I do. I attract others who are keen to create new forms of organization and society.

Since I am aware of the existence of multiplicity of perspectives in connection with multiplicity of identities, I see collaboration as a pre-requisite to justice. Exercises of unilateral power feel wrong to me. I will share power and involve others in decision-making, sometimes to a fault (not recognizing that I myself am unilaterally insisting on collaboration). I myself will feel betrayed if excluded from decisions. "Nothing about us without us," I insist, and I categorically reject the legitimacy of any initiative that doesn't have justice-denied people sitting at the table. I invite conflict and have some ability to create shared vision across differences. Unfortunately, many of the groups I work with end up having an oppressor who recreates the very dynamics we are trying to work against, and they destroy the group. The bitterness of these repeated experiences of betrayal feeds my disillusionment with the world and renews my commitment to fight.

---

[8] There has been some suggestion that the alt-right, white supremacist movements emerging in the 21st century are also a form of rejection of meritocracy and an alternative response to neoliberalist status-quo – See Sandel (2020). On the surface there are similarities between the alt-right movements and the social justice warriors. I do not have enough familiarity with the alt-right communities to responsibly speculate on them, but the question is worthy of our collective consideration.

In the interpersonal space, I commit to the Platinum Rule ("treat others as *they* want to be treated") and I will stand up for your self-expression - your right to be identified by a new name and pronoun every week if you want to. I have no trouble calling people out, I believe survivors as a matter of principle. I am done with oppressors getting away with their behavior and I am not interested in hearing their excuses. Despite my talk of oppressive systems, my rage is often directed at individuals embodying them, including whoever happens to be in charge in my organization. Sometimes the people I rile against are those I am raging on behalf of: the few "minorities" who have made it to leadership ranks – partially thanks to my own lobbying to put minorities into positions of power ten minutes ago. I am not aware of the irony that I quickly destruct the solutions I helped to construct, when they don't match up exactly with my idealized vision for them.

In group and organizational settings, I am likely to read a situation exclusively in terms of the patterns of oppression, dismissing personal contributions almost entirely: If the person of colour doesn't get the job, that is undisputable evidence of racism. If people disagree with the woman in the room, that's because they are sexist. If a queer person is not excelling, that can't possibly have anything to do with their competence and to suggest otherwise is homophobic. Even though on the face of it I am a fan of inquiry, I will shut it down if the oppressed are being questioned. Inquiry is violence when it discomforts the oppressed. Do I sound like I hold double standards in favour of the oppressed? That is because I do! The world has been made on double standards! The only way to correct for history is to turn the tables.

Transforming

Skillful negotiation of the polarities, contradictions, differences, and incongruities between people's talk and their action is my main preoccupation as Transforming. I have strong views and politics, and have been steeped in deeply ideological waters – but somewhere along the way I burnt out as a JEDI warrior. I am aware of the dark side of movements, the impracticality of their critical approach, the brutality towards their own members. I am disillusioned by dogma and see purity claims as empty and antithetical to the project of making a better world. I am not interested in replacing one form of silencing with another, even if there is some resemblance of justice in that. I feel strongly that the liberation and transformative justice we are seeking to bring about needs to be embodied right now in all of our actions. It is sometimes observed that when people first grow into an action-logic they feel annoyed and impatient with the action-logic they have just transcended. Perhaps that explains my frustration with Redefining.

As Transforming in the JEDI space, I believe fiercely in justice, the manifestation of love in public, as Cornel West has said. I don't dismiss critical analysis but I hold conviction at arm's length to be examined. Part of being equitable means that I am as critical of my own frameworks as I am of others, and I am learning to do this with generosity and care. I agree with Redefining that the world orders are fundamentally unjust and we need to bring this house down. I also know that you can't dismantle weight-bearing walls when there are no other supporting structures (R. Soutar, personal communication, Jan 15, 2021). If you demolish quickly and indiscriminately, you crush the inhabitants, and those who are already marginalized are likely to suffer most. I am strategically focused on building new supporting walls in order that the old walls can be taken down. I stand for transformative change in vision, strategy and tactic, but am not ashamed to use conventional tools – diplomacy, data, incremental change tactics – in those moments when they are more effective than revolutionary tools in moving us along.

I am keenly aware of the influence of systems *and* individual agency when it comes to JEDI issues. In moments of conflict, I don't assume that what is happening is strictly interpersonal, nor do I read it purely as systemic. The conflict between men and women in my department over who is doing more of the institutional housekeeping or emotional labour, is not *only* their fight. It sits against the backdrop of patriarchy and the unconscious expectations of gender roles that subtly colour our thinking and action. I recognize and make these patterns and histories explicit, but reserve enough of a beginner's mind to then look at the specifics of the situation. The way we undo patriarchy- and other oppressive systems- is through how we handle specific situations like this. Engaging this conflict can lead to personal development (the parties cluing into how they are responsible for [co]-producing the situation), new local strategies (revising team arrangements and feedback mechanism) and systemic change (a reframing of what types of labour we value as an organization, and a tracking system to make workload distribution transparent and equitable). Systems and individuals are much more interdependent than typically acknowledged. Individuals – even those who have done harm – have the capacity to do better when we engage in "principled struggle" (Lee, 2020), and give them a chance for a do-over (T.M. Nahanee, personal communication, Mar 15, 2021). And transformative change can happen when there is a critical mass of individuals brave enough to live in truth (Havel, 1978).

My worldview is shaped by an understanding of polarities – situations where there is truth and wisdom on more than one side of an issue (Johnson, 1992) – and I have practical skills in working with them. I lean in the direction of working with groups and I see the task of leadership as caring for the whole of the organization. I construct teams and decision-making tables that are inclusive of the "diversity tensions" we are navigating (Thomas, 1996). In my circle there are many unusual suspects and unlikely allies. I am as concerned with representation (which identities are present) as I am with the meeting of different paradigms and points of view. If we can't have Indigenous youth in our meeting (they have better things to do, and we're not yet decolonized enough for them) I at least introduce a reading or a song or a ritual that might bring their voice and presence into the space. I don't simply give everyone equal opportunity to speak. Instead I use my power to create spaciousness and amplify the voices of those who have been on the margins – then create careful spaces for the voices of dominant groups too, because we won't make any lasting transformation if they nod in agreement out of politeness or fear or numbness, and then go back to their desks wounded and un-transformed and continue to do what they have always done. I see the concept of diversity itself as being expansive – not only about identity markers, but about differences in action-logic, in feeling states and perspectives that are taken up – sometimes just momentarily – by different people at different times (Thomas, 1996).

I am quite adamant that we need to create spaces where people from different walks of life can enter the conversations on JEDI topics, even if it means some are going to be clumsy and say the wrong things (Joseph cited in Stayton, 2019). Sometimes I take on a third-party neutral role, in order that I can stand slightly outside of polarized situations and help with a genuine exploration of the views. I bring everything I have – theory, data, truth-telling, charm, humour – to this collective meaning-making and attempt at co-creation. I have learned too that it is wrong to hide behind my "neutrality." There are moments when I need to draw strong boundaries, protect a group from itself, practice generous exclusion (Parker, 2018), confront hypocrisy, raise a mirror up to a community, and make myself unpopular. In my best moments I have the feeling that I am lending my maturity – my ability to hold multiple truths and give people some grace – to the group or community I am working with.

Alchemist

As Alchemist, I stand a step back and look on. I see us – organizations, communities, families, societies, ecosystems - in this moment of struggle, real pain, real effort and real potential. I see us somewhere on the arc of history, which, as Martin Luther King says, is long and bends towards justice – but also looks a lot like a collection of spirals in its non-linearity. While I walk the path of transformative justice shoulder to shoulder with passionate colleagues, I feel less certain about our prospects and less attached to specific outcomes. Perhaps it is important that we win this election battle, pass this new policy, create this new practice, re-build the house so that the walls are not made of oppression, bring some light into the darkness. But also perhaps this is *not* what is important. Perhaps this is a time when we need to go into the darkness fully, perhaps the order needs to fall apart completely, perhaps our organization, our civilization is ready to die, and it is not for us to control or even envision what the next wave of existence might look like. I am so aware that sometimes when it looks like we've won, we have actually lost, and other times when it feels like we have fell on our faces, we have actually succeeded.

I feel sad for where the world is, and simultaneously touched by its beauty. I feel somewhat detached from the world-remaking effort, and at the same time very much in touch with its moment to moment struggle. I feel resigned to what there is and simultaneously committed to acting towards change with integrity each step of the way. Often I seek out intimate conversations with just one or two others, speaking my vulnerabilities, asking about their deepest truths, feeling the shakiness of the ground underneath us as we find no answers. Even more often I sit under a tree by myself, feeling these feelings, holding these contradictions inside me with tenderness, listening into the dark, wondering into the mystery of what is unfolding.

When I think about justice, I think about inter-species justice and the possibility of human societies [re-]discovering relationships of reciprocity with other beings as well as each other (Kimmerer, 2015). My sphere of care extends far and wide. I love all the children or all species for all time (McDonough, 2002). When I think about myself, I am far more aware of my privilege than my victimhood. I feel so privileged to be getting such enjoyment out of the warm cup of tea in my hands right now.

In all honesty, I am no longer that invested in organizational life. I find it lonely, and it might be time for me to step off. But while I am here, I am here with an existential awareness and attendance to the present moment. I spend time preparing for collapse of organizations and societies, putting away valuables in a time capsule for future days, and attending to the grieving process of those around me. My role is really fluid and my time is structured by a clear sense of priorities that aren't spelled out in my job description or work plan (did I even remember to make one of those this year?) Many people seek my council, and an equal number have written me off as the half-mad fixture of the organization. I am equally happy to name the elephant in the room, play the peace-maker, break into tears in the middle of a meeting, or be the person everyone needs to blame to feel better. I show up the next day and see what is required then. And if I am fired, it doesn't matter all that much. I am Opportunist, Diplomat, Expert, Achiever, Redefining, Transforming. I am Nelson Mandela in prison, seeking out and talking to the young radical prisoners, learning from them and drawing inspiration from their energy, not getting triggered by their militancy. I tease them and nudge them towards more inclusive visions of justice while they sharpen my own thinking (Raffanti & Gregory, 2012). I take delight in our mutuality: the significance of their impact on me and my impact on them.

Implications for Practice

The exploration of the action-logics and their differential capacities for engagement with the complexity of JEDI issues highlights, first of all, the difficulties of working in this space – but that's not exactly a revelation. The question is "so what?" What does this exploration tell us in terms of what there is to do, or, how those of us who care about JEDI could become more effective actors in the middle of this space or on its peripheries? Here I articulate some observations that occur to me, particularly as I think about later action-logic actors (Redefining, Transforming, Alchemist) in organizational settings.

Redefining at center stage – What strikes me most, as I write this paper in early 2021, is that the Redefining action-logic is the most central character in the dramas of the JEDI movement in this moment in history. The power of Redefining comes from its access to fresh, highly relevant truths and a closeness to the reality of those who are suffering. Society is hungry to see the world anew, to reframe everything, to challenge the status-quo – evidenced by the fact that "everything you knew about X is wrong" is a most effective clickbait on social media. Drawing on decades of critical writing, community organizing and artistic practice, and with the help of the internet, Redefining has the means at their fingertips to create and grow social movements in unprecedented ways. Redefining energy can mobilize, in particular the survivalist instinct of Opportunist (thus the militancy and potential for violence), the tribal mentality of Diplomat (thus the enormous pressure to conform within the JEDI movement), and the need for precision of Expert (thus all the rules about right and wrong)– which is to say that the JEDI movement is also full of early action-logic actors. The status quo against which they stand up is characteristic of Achiever mentality. Achievers are for the most part pretty perplexed by the JEDI movement ("why are they so angry?") and will try to co-opt its Redefining energy into their own lucrative fold ("here, have part of the throne"). Meanwhile, Transforming finds it hard to have patience for the purism of Redefining ("why can't they grow up already?") and is likely to dismiss it out of hand ("they are just playing identity politics").

If this paper has done one thing, I hope that it has created some understanding and affection for the Redefining action-logic as it shows up in the JEDI space. Too often in organizations and communities, I see Redefining villainized, dismissed and disrespected. I am under no illusion that Redefining is perfect, and have hinted through this paper at its shortcomings: a propensity for righteousness, a dogmatic over-emphasis on inclusion, a counter-productive purism, a harshness in dealing with anyone seen to be faltering, or not "woke enough.[9]" Nevertheless, the vilification and straight-up dismissal makes me sad because Redefining is the carrier of uncomfortable truths we need to hear in organization – truths we are currently mostly shutting out. It also scares me because the more these truths are denied, the more extremist the Redefining among us will become, and that path is leading us to the edge of violence within JEDI spaces, and throughout our organizations and communities.

I tend to think that the likelihood of the JEDI movement succeeding in liberating us may depend on our collective finesse in working with the Redefining energy, both in ourselves and in others. Transforming and Alchemist: this is on us. First we need to pay attention to how much time we spend acting from Redefining, and how much of that is in fallback or out of a need for easy belonging. We need to exercise the responsibility of our developmental rank, which is to be patient with and respectful of people at other stages of development. We need to be alert to the hubris that can come with the latest action-logics. When we are attacked by Redefining, we need to put aside the fact that it feels harsh and unfair, and should instead look at it with honesty and ask ourselves: where is the grain of truth? We need to validate Redefining colleagues when they are correct, and be courageous in articulating why they are incorrect when that is in order. We could bring Redefining colleagues into the rooms where we grapple with the complexities of what we are facing and have them engage with us in figuring out how to manage various polarities responsibly – instead of locking them out of the room which sets them up for opposing whatever pragmatic solution we come up with. The most productive path out of the stand-off with Redefining is, ultimately, a developmental path in which our Redefining colleagues grow, and with any luck we do as well.

Potential for JEDI conversations as sites of development – One of the most useful things that leaders at the later action-logics could do is to do some horizontal development around JEDI issues. So far in this paper I have focused a lot on late action-logic actors who are already in the JEDI movement, but my observation is that most highly developed organizational leaders are pretty illiterate when it comes to JEDI. Make no mistake: just because you are a late-action logic leader that doesn't mean you can be effective in interactions across difference at a time of such polarization. We cannot be effective in the JEDI space – and I would argue we cannot be effective as organizational or societal leaders at a time when these issues are front and center – if we don't take an interest in the history of Asian Canadians (which is entirely different from the lived experience of Black or Indigenous folks), if we don't make an attempt to understand the lived experience of colleagues with disabilities, if we don't learn the current language for talking about trans folks or practice referring to non-binary friends with they/them pronouns. Sometimes I hear colleagues say: "but there is no way I am going to learn everything about everybody – that's just postmodern foolishness." I agree with the first part of this statement, but to make no attempt to learn because there is so much to learn seems even more foolish to me. Learning about the concerns of those around us is not unreasonable. We could add it to the list of impossible things we already strive do, without putting expectations of perfection on ourselves and others.

---

[9] There is a significant and powerful literature from within the social justice movement(s), by queer and racialized activists and writers that question the ways that the orthodoxies characteristic of a less mature Redefining culture are playing out, and propose transformative and alchemical alternatives. Of note among these texts are Frances Lee's essay (2017) *Excommunicate me from the church of social justice*, Kai Cheng Thom's book (2019) *I Hope We Choose Love*, and adrienne maree brown's book (2021) *We Will Not Cancel Us*. These texts are essential reading for anyone concerned with the ethics and practicalities of supporting the maturation of JEDI efforts at this time in history.

In a different vein, one of the best gifts of learning about JEDI issues may be that it acts as a kind of Trojan horse for vertical development. I think it is possible for us to start thinking of and designing our JEDI conversations, trainings, dialogues and conflict engagements as developmental opportunities – by which I don't mean that we start talking about action-logics, but rather that we think of what we're doing not only as teaching skills or concepts, but as enabling new and expansive mindsets – pursuing vertical development goals as we do horizontal development. The centrality of *difference* to the JEDI conversation, and its invitation to be self-reflective on our own complicity in injustice, could make it a potent space in which people can be compelled to grow. If the three conditions necessary for vertical growth are colliding perspectives, elevated sense-making, and heat experiences (Petrie, 2015), I can hardly think of a space where those three conditions are more present than in any good JEDI conversation. Ideally, our JEDI learning interventions would meet people where they are at (for example, the Experts would get PowerPoint slide start with) and then stretch them into future action-logics (for example, the Expert will then get a second set of information in tension with the first, plus a small peer group and a polarity mapping tool that would enable them to start making sense of the contradictions together). It excites me to think of the innovative designs this reframe of JEDI learning as vertical development can make possible.

Implications for the question of motivation – The exploration in this paper has made visible to me that there are multiple starting points in terms of *why* organizations and people within organizations are signing on and creating departments or initiatives to do JEDI work. For Diplomat and Expert, the motivation is to comply with regulations. For Achiever, it is the business advantage. For Redefining, the motivation is ethical and JEDI is a good in itself. For Transforming, JEDI is the instrument towards a goal of love and mutuality. I can say that in my workplaces all of these motives have existed at the same time and part of the battle around JEDI issues (what wording we should use, what initiatives we should prioritize, what story should we tell) is actually a conflict over which motivation should guide the effort. So often I witness people – who are all committed to JEDI – feel either perplexed or betrayed by each other because of their differences in how the understand "the cause." But is it really such a game-stopper if we don't all want what we want for the exact same reason? Could we see the strategic advantage in agreeing on the destination and the basic path to get there, even if we're travelling for a variety of reasons? If we want expediency in JEDI initiatives, perhaps there are opportunities for alliances across the action-logics. Perhaps we need to make the conversation about motivation more explicit more often, and see if the clarity about the multiplicity of our purposes gives us the ability to consciously build these alliances.

When the JEDI movement looks in the mirror, it sees many faces reflected back. I can only hope that giving names and definitions to some of these faces enables all of us who see ourselves a part of this movement to take our next steps with more awareness and mutual responsibility to one another.

Response to Erfan

Amiel Handelsman[1]

*In **The Many Faces of JEDI: A Developmental Exploration**, Aftab Erfan describes how each developmental action-logic makes sense of justice, equity, diversity, and inclusion (JEDI) initiatives within organizations and suggests implications for later-stage people. In this response, I describe six ways her paper contributes to a better world and suggest three ways to make her vision even more expansive and enticing.*

Acknowledgements: Big thanks to Hilary Bradbury and Mike Cohen for commenting on earlier versions of this.

Editor's note: Amiel Handelsman's response to Aftab Erfan's article arrived just prior to publication of this issue. I sent Aftab Amiel's response, and from her holiday retreat time, she sent the following note.

> I could not be more delighted that my little "many-faces paper" has been met with such thoughtful engagement in anticipation of its publication. I wholeheartedly appreciate Handelsman's response – his highlighting of key concepts which made me feel understood, and his colourful rephrasings that helped me see my own thoughts in a new light – even as I observe that Handelsman and I have a somewhat different sense of what is "timely" in terms of a vision and next steps for the JEDI movement. Admittedly, the Redefining within me had a small tantrum over the fact that my 19-page paper is appearing alongside a 16-page response by a [nominally] white man (will they ever just pass the mic?!). But I am excited for the dialogue that has been opened here, and I hope that the length of our contributions will provoke, rather than douse, more of this conversation in our communities.

Introduction

I am energized by Erfan's "many faces" approach to JEDI, commitment to embracing every action-logic, and plea to later stages to cut Redefining some slack. This paper raises the bar for all of us engaging in JEDI work and should prompt thoughtful skeptics of it to pause before launching their next critique. It provides revisioning of the highest order.

SOME RIGHTS RESERVED

If we are to succeed in this venture, it would be useful to build an even larger tent of intentionality for all those new JEDI faces, bodies, and hearts. This means drawing more people into the conversation and offering a sufficient variety of aims and experiences to keep them engaged. Exploring one's complicity in injustice gets some people into the tent, but not everyone, and it certainly doesn't keep them there for long. Such is the nature of projects conceived by the Redefining action-logic, however broadly imagined by later action-logics and however many perspectives they embrace. As I feel into the Redefining action-logic within me, I trust it to light a fire in my belly, awaken sensations in my heart, and prompt me to question what I've taken to be true. At this point, Redefining has done most of its job. To take the next steps – imagining a new future, holding it in tension with the brutal facts of today, and initiating effective action – I need a wider and more reconstructive approach.

What Makes This Important

1. Explanatory Power

This paper is the first effort I've seen to make sense of the complexity of JEDI initiatives by walking through the developmental journey step by step (or, rather, stem by stem[2]). The feeling I had upon reading it was a mix of gratitude and astonishment. Neither JEDI nor vertical development were new to me, but the meshing of them together in such an elegant and generous manner struck me as novel and useful.

When I say "useful" I am referring to the paper's explanatory power. It helps us make sense of what is otherwise confounding. Take, for example, the opening anecdote about the graduate student and department director. I can imagine dozens of ways to interpret this story. Most of them don't explain what's going on in a way that produces timely action. Some interpretations would make things worse. It is into this scene that Erfan enters with a question: what if the student has a more complex system of meaning making than their boss?

Boom. Flash of insight. Now I have a way of explaining the tension between these two individuals that opens vistas. As a reader, I feel compassion for both actors. There is nothing wrong with them. They are both in full integrity with their action-logics. Putting myself in the shoes of the student, I begin observing the relationship differently. I stop expecting the boss to respond like I would. I pause before taking actions that, due to the developmental gap, are likely futile. I start accepting my boss for who they are – like, Erfan says, a younger sibling. Or consider a second analogy: a short person playing basketball. If you throw an alley-oop pass above the rim to a 5 foot 6 player, it's unlikely they will jump that high, much less dunk it in the basket. The first time you realize this, you stop getting angry when the play fails. The second time, you don't throw the pass.

The Many Faces of JEDI is filled with illuminating explanatory moments like this. I personally resonated with Erfan's description of the Achiever. After graduate school, I spent a year helping a community foundation explore ways to support Black American entrepreneurs in the city of Detroit. Each day, I drove into the city to meet with pastors, directors of community development organizations, and bank officers. *There must be a way to align all these interests…but how?* Each evening, I drove back to my Ann Arbor apartment, the walls of which were filled with personal declarations, inspirational quotes, and professional goals. Achiever artifacts, to be sure. In the end, I left the project before it was off the ground. My public explanation was a desire to help a former professor of mine run for Governor. Privately, I felt myself floundering. Why had this happened? At the time, I didn't have an explanation and felt ashamed. Nearly a quarter century later and prodded by Erfan's descriptions, the explanation is clear: my Achiever action-logic was no match for the complexity of the undertaking. Writing these words produces the opposite of shame. It relaxes me, and I feel acceptance, because it would've been unrealistic to expect anything different from someone at that action-logic. Perhaps it's time to update Thomas Harris's classic book about transactional analysis, *I'm OK, You're OK*, for a new era. The new title: *My Action-logic Is OK. Your Action-logic Is OK.* Beneath my flippancy is a serious insight: in today's world, mutual acceptance across the developmental trajectory goes a long way.

---

[2] Erfan writes, "Dimensions of development are distinct from each other and provide scaffolding for one another like bean stems."

A second example shows up in the section on the Expert. If you've ever felt puzzled by the propensity of JEDI professionals to count, count, count, this section provides a helpful explanation. Metrics and dashboards about hiring and retention aren't signs of a pathology (what would we call it: Numberitis?). Nor does fervor for formal training classes represent stunted creativity or stubborn refusal to realize that people learn through experience.[3] Instead, these habits are in full integrity with the Expert action-logic. Although we might not need as much formal training or as many bar graphs as Experts are wont to provide, we *do* need some, not only to satisfy Experts in the room, but also because human endeavors benefit from data, and the desire for data is part of who we are. Once again, describing how an action-logic approaches JEDI helps us understand why folks do what they do. This new interpretation evokes patience for behaviors that can frustrate later stage folks, reminds us of how that behavior tangibly benefits us (when supplemented by other perspectives and approaches), and invites us to embrace that very dimension (don't you secretly love a good histogram?) within ourselves.

2. A Full Developmental View of JEDI

Anyone who hangs around so-called integral circles for more than a few minutes quickly encounters frustration with the Redefining action-logic, particularly its stance toward diversity, inclusion, and antiracism. This was true in the fall of 2000 when I joined the Ken Wilber Reading Group in San Francisco, and it is true today. My colleagues and I invest an extraordinary amount of attention in critiquing and lamenting this single action-logic. Sometimes I wonder if we've all had microchips with tiny speakers implanted in our ears that play the audio version of Boomeritis[4] over and over again every night. One reason for the irritation, as Erfan points out, is that we are always fighting back against the action-logic we just transcended. It's like high school students who are embarrassed by how ridiculous middle school was. ("I would never want to go back there!").

---

[3] The classic 70/20/10 rule, a back-of-envelope summary of a two classic Center for Creative Leadership studies, says that 70 percent of learning comes from on-the-job experience, 20 percent from peers and mentors, and only 10 percent from formal training and books. Critics of formal training like to point out that in practice, the ratios are exactly the opposite.

[4] A book written by Ken Wilber (his worst, in my assessment) that highlights the excesses and absurdities of extreme academic postmodernism.

Another reason is that many folks at the Transforming action-logic live, work, and play in the Redefining milieu. A close friend of mine does business with dozens of yoga teachers and spiritual practitioners. He frequently gets attacked for "appropriating" Hindu culture in his music even though he honors it with unflagging consistency. This is an example of what an old mentor of mine called "no good deed goes unpunished." It is often the Transforming folks most committed to justice and diversity that get flogged because (a) they're nearby and (b) they violate a sacred principle of deconstruction: thou shalt not reconstruct. Being on the receiving end of this is particularly painful when you've dedicated yourself to honoring diverse traditions. Unlike me, my friend doesn't spend hours upon hours coaching managers in corporations and businesses, so he doesn't frequently encounter the frustrating aspects of Expert and Achiever. Is it any wonder, then, that he gets exasperated by the poisonous dimensions of Redefining yet barely says a word about earlier action-logics?

There. I've now devoted a full paragraph to Redefining. That's enough for now, and here's why. An exclusive focus on this action-logic – as though it were the only game in town – may be understandable, even predictable, but it isn't serving us very well. Conversely, we have much to gain in conversations about JEDI by examining the gifts and limitations of *every* action-logic. Erfan's paper provides such a comprehensive treatment.

There are three reasons why I appreciate this "many faces" approach. First, it reminds us that there are legitimate motivations for participating in JEDI at (almost) every action-logic, and we could do worse than accepting them on their own terms. As Erfan writes, "Could we see the strategic advantage in agreeing on the destination and the basic path to get there, even if we're travelling for a variety of reasons?" To me, this question offers a twin-challenge for people stepping up to JEDI leadership: one, design interventions in ways that honor all of these disparate motivations and meet the social needs (e.g., status, certainty, autonomy)[5] underlying them; two, frame such interventions linguistically and emotionally in ways that resonate with each action-logic. This second point is a version of the old advice, "Don't just do good things for people. Tell people what you are doing for them so they can recognize it." Each action-logic responds to its own enticements.

Second, in later-stage circles, Redefining gets more than its share of not only vilification, but attention, period. Imagine a pie chart that shows how much time people spend discussing each action-logic's strengths and foibles around JEDI. Redefining would fill up nearly the entire pie! Slices representing the other action-logics would be barely visible. This isn't an argument for spreading criticisms more evenly (though that's not a bad idea). By omitting exploration of other action-logics, we make it harder to design later stage interventions and less likely they will succeed. After all, how can you create practices and scaffoldings for action-logics you rarely discuss? On this note, Erfan's analysis fills the void.

---

[5] I'm thinking here of David Rock's SCARF model of social needs that comes out of neuroscience. SCARF stands for status, certainty, autonomy, relatedness, and fairness. According to the research Rock cites, being denied these social needs shows up similarly in scans of the brain the brain as being physically threatened. In claiming that these social needs underlie the motivations of the action-logics, I'm making a large claim without providing any basis for it. A topic for another day…

A third reason to give due attention to earlier action-logics is that it reminds us (yet again!) that Redefining is itself an enormous evolutionary achievement. Just look at the limitations of what comes before (see, I told you this wasn't a bad idea): As Opportunist, to quote Rodney Dangerfield, I look out for number one while trying to avoid stepping in number two. Useful at times, but not as a guiding motto! As Diplomat, I exert enormous energy trying to match the JEDI moves and outfits of people around me and "live in constant fear of being disposed of by my in-group." Exhausting! As Expert, I "depersonalize conflicts and objectify the problem" and lean too heavily on data and metrics. Where's the juice? As Achiever, I'm all about uplift, progress, ROI, and doing well by doing good – yet don't have the stomach to deeply explore injustice, trauma, and inequity, much less consider how those affect me on an interior level. Too much sugar, not enough spice, and no medicine that tastes sour but heals the body!

The point, again, isn't to spread vilification around evenly, but to remember that none of these earlier action-logics is up to the task that Redefining uniquely fills: looking candidly at the horrors, contradictions, and disparities that stain the past and contribute to suffering today and welcoming everyone who has been left behind. In this sense, Erfan fulfills her primary stated hope of building understanding for Redefining in the JEDI space. She does this not only by showing what I can see and do at Redefining, but also by demonstrating what other action-logics *cannot* see and do. Redefining means I'm only three-fourths of the way up the mountain, but that in itself is an impressive climb. I can see things from here not visible from below.

3. A Call to Embrace Redefining Within Ourselves

In a section directed to Transforming and beyond action-logics, Erfan writes, "We need to pay attention to how much time we spend acting from Redefining, and how much of that is in fallback or out of a need for easy belonging." Her invitation here, I think, is to notice how and why such folks participate in the less healthy dimensions of Redefining – almost as a way of saying, "Watch out." Yet, given her purpose of viewing "many faces" from both sides, I suggest we (anyone who identifies with this tiny slice of humanity at such later stages) interpret this invitation more broadly. What if we made it a practice to notice not only, as she puts it, when we fall back into Redefining, but also when we embody the best dimensions of Redefining? Think of this as appreciative inquiry applied to an action-logic that isn't itself wired for appreciation.

Recently, while reading a book about mid-19th century United States (Eric Foner's *The Fiery Trial: Abraham Lincoln and American Slavery*) I was reminded that for years, much of the anti-slavery movement favored colonization – moving both "free" blacks and the would-be-emancipated to another country. This left me with a sick feeling in my stomach and the thought, *So, even the good guys weren't so good*. Before long, I started feeling shame that I had forgotten this fact – that for years I had considered anti-slavery synonymous with recognizing the full humanity of Black Americans, which was not the case. Then, I noticed anger rise in my chest. My whole body felt hot. I wanted to *do* something, to right this wrong, to make this better, to shout at the sky, "Everything you told me about Abraham Lincoln is wrong!" This experience, which transpired over all of ninety seconds, was a form of contact with the Redefining action-logic within me. *Things aren't as they appear. Seemingly noble motives are impure. And behind it all is power, raw and unrelenting.* Although these statements don't summarize my view of the world, they cover a lot of important ground. Acknowledging their validity, however partial, contacts me with a part of myself that I love and would not want to live without.

Experiences like this (and not all happen while reading history books!) have a second benefit. They help me feel more compassion for others' Redefining expressions, however irritating, because these expressions live within me. You might describe this as wise. I think of it as pragmatic. When someone is accusing me of "white fragility," for example, I *need* this reminder that Redefining lives in me (along with other inner and outer conversation microhabits[6]) in order to stay centered and grounded rather than fight, flee or freeze. In other words, it's in my self-interest (both enlightened and narrow) to keep my Redefining parts nearby and ready for a spontaneous embrace.

The same, of course, is true for all of the action-logics. Although they might not all want hugs – Achiever might prefer a high five, Expert a star of distinction, and Diplomat a laminated membership card – each action-logic deserves to be embraced for what it is and what it offers. On this note, I was inspired by Erfan's use of the first-person voice throughout the paper. I've seen this done with other development frameworks – most memorably for me with the Enneagram. Yet this is the first time – or, at least, most meaningful one – I've witnessed it in writing with action-logics. How refreshing and inspiring. May we all follow this positive example.

4. A Preview of Emergent Capacities

It's often said that life at later action-logics can be a lonely place. I remember Susann Cook-Greuter writing something like this on the sentence completion test (as it was then called) she scored for me twenty years ago. I instantly felt less alone. A similar thing happened a decade later in a workshop I took with Terri O'Fallon. She described how often folks at Transforming and Alchemical stages are misunderstood and misinterpreted. I instantly felt better understood and more accurately interpreted.

Herein lies a deep gift in reading how the Transforming and Alchemist action-logics make sense of JEDI: Being pointed toward your current or potential capacities. With Transforming, I am reminded of what's possible right now. To begin, there is "building new supporting walls in order that the old walls can be taken down," and using whatever tool, practice, or approach meets the moment – including the act of creating create safe and brave spaces[7] for folks to stumble around with JEDI. There is also embodying love and transformation in this moment, an aim I describe in my work as not just *being the change* but also, because humans live in conversation, as *speaking and listening as the change*.

---

[6] Conversation microhabit is my term for a tiny action we take while speaking or listening. Inner conversation microhabits include taking a four-six breath (inhale to a count of four, exhale to a count of six), doing a quick body scan, wiggling your toes, and silently saying a particular word like "patience" or "I got this." Outer conversation microhabits including paraphrasing, gently probing, appealing to nobler intent, and redirecting the conversation. In collaboration with my colleague, Mike Cohen, I've created *conversation skill drills* to practice these microhabits in a high-rep, high-reflect fashion.

[7] I use the term "safe and brave" to distinguish these spaces from others that are only safe (in that they don't call upon courage or build resilience) or only brave (in that they don't provide sufficient psychological safety).

An example of speaking as the change is framing a difficult conversation around, say, an organization's hiring practices, as "my side of the story, your side of the story" and being aligned with this in my body. Such words don't just describe a pre-existing reality. They bring a new reality – the possibility of holding your perspective and mine as equally worthy of consideration – into being. As you share your side of the story, I can sustain this respectful differentiation of perspectives by paraphrasing what I've heard and gently probing for clarification. Meanwhile, I can listen as the change by making my habitual interpretations (many of them filled with cognitive bias) objects of awareness. I name them in my mind just as, during meditation, I might name a thought passing through my mind. Similarly, if the other person expresses strong emotion, I can note the physical sensations this generates in my own body and feel how these are my sensations, not theirs. This, in turn, reminds me that they, not I, are generating the strong emotions they express. This is one example of how transformation happens in the moments of speaking and listening.

With Alchemist, I see what lies ahead. How often do I "hold contradictions inside me with tenderness?" Or "wonder into the mystery of what is unfolding?" Not so often, my friends. Not so often. These are potentials – enticing, even beguiling – but potentials nonetheless. When Erfan describes such ways of being, particularly in the context of JEDI, I feel called to embody them, almost as though being given pointing-out instructions for meditation. "*Amiel*," the voice whispers, "*This is who you are*."

5. Marginalization as Accelerator of Vertical Development

Erfan suggests that adversity is a powerful force in fostering psychological and spiritual development. Given the examples she provides – "Black, Indigenous, refugee, disabled, trans and queer folk" – I think that in the JEDI context she means a particular form of adversity: participation in marginalized groups. Although she mentions other adverse conditions like poverty, war, and illness, it's hard to tell if the growth opportunities she connects to marginalized groups also are available to people who experience themselves as individually marginalized even if they don't belong to a marginalized group or folks who've experienced adversity not related to marginalization. Would "two-eyed seeing[8]," for example, be accessible to a straight white man who grew up poor in Appalachia, felt like an outcast around wealthier kids in college, was sexually abused by the football team doctor, and has now returned from Afghanistan with PTSD and a sense that nobody understands him? Perhaps someone has researched this.

Either way, Erfan's core point here stands: The everyday lived experience of being different, outside, and overlooked creates as fruitful conditions for growth as a carefully designed 12-month training program (and, if you recall the CCL[9] studies cited earlier, probably better). Confronted by surplus complexity, marginalized folks learn “to be alert to the nuances of a situation, moment-by-moment unfolding of group dynamics, presence of multiple conflicting perspectives and visions, the influence of the rules of the game and their arbitrariness, and access to creative problem-solving and bold alternatives.” These are remarkable capacities that represent the very best of what adult development offers. If marginalization opens the door to such capacities, it is a door that is pivotal for the future of humanity (see: Climate change, pandemics, liberal democracies on the rocks, and gun violence). Having said that, I assume that the people she describes – primarily university students, perhaps – represent the leading edge – the exception rather than the norm – of their identity communities. (It would be interesting to study what combination of inner resources and outer support nurtured their growth beyond that of, say, elementary school classmates of theirs who didn’t develop such capacities.) If so, perhaps the takeaway here is that this leading edge of marginalized groups is larger, more agile, and less dependent on formal programs due to the life experiences of the people inhabiting it.

---

[8] "Two-eyed" seeing is a capacity for navigating complexity that is associated with people from indigenous groups and that, Erfan writes, "comes from a daily need to survive in contexts where one doesn't quite fit in." As I understand it, this is a later stage capacity than "double consciousness" as W.E.B. DuBois defined it: "always looking at one's self through the eyes of others," which resembles Robert Kegan's Socialized Mind. A closer analogy to "two-eyed" seeing is Ralph Ellison's reinterpretation of "double consciousness" in his essays and the novel Invisible Man. For Ellison, double-consciousness is not merely a burden. It is also a useful capacity.

[9] CCL is the Center for Creative Leadership

In making this point, Erfan takes pain to clarify that she isn’t glorifying oppression or injustice. I read this as a nod to the Redefining within us that might suspect otherwise. However, for anyone hanging out in Transforming or Alchemist, this disclaimer seems unnecessary. Acknowledging that your life conditions have helped you grow suggests nothing about the morality of those life conditions. It describes what has happened. It does not assess the goodness of those experiences. For example, one of the most profound growth experiences of my life happened after my wife and I lost our first child and only daughter shortly after her birth. (She was born just a wee bit too early). This loss and the trauma that accompanied it rocketed me off on two simultaneous journeys: One into grief, the other into positive psychology. I would not be the same person today without these experiences. Yet every time I learn that someone I know is pregnant, I pray for their baby’s good health, because I would not will on anyone the agony of losing a child. And I am mindful that the experience of infant loss is and has long been significantly more common in Black American neighborhoods and families. In fact, the very first paper I wrote as an undergraduate public policy student was about expanding prenatal care for low-income mothers. At the time, I associated infant loss with so-called “blacks” in the inner city. It had nothing to do with me. Today, I know otherwise. Somewhere in there is a lesson about paying attention to others’ suffering, not only as an act of love, but because “but for the grace of God, go I.”

6. A Trojan Horse for Vertical Development

Erfan writes that “the centrality of *difference* to the JEDI conversation, and its invitation to be self-reflective on our own complicity in injustice, could make it a potent space in which people can be compelled to grow.” Here she is writing not only about people who have been marginalized, but everyone, particularly folks centered at later action-logics.

I had a similar thought in the aftermath of George Floyd’s murder. It seemed as though a window of opportunity had opened, not only to reduce police violence and other injustices “out there,” but also to spark profound individual and collective growth “in here.” In my writing I experimented with several different ways of articulating this. For example, it felt important to offer an alternative to the idea that antiracism is merely about being an “ally” to others’ projects. Claiming your own self-interest, as opposed to acting from altruism (a motivation that Ibram X. Kendi criticized in his first book, *Stamped from The Beginning*), struck me as more likely to evoke sustained commitment. It also seemed more in tune with honoring the full humanity of Black Americans (if I'm just doing this for you, what does this say about you?) as well as more likely to earn others' trust (because it doesn't take a cynic to hear declarations of pure altruism and wonder about the speaker's sincerity).

Since then, I've met many later stage folks intrigued by the opportunity to grow through JEDI and antiracism work. Although most have limited appetites for "pure" Redefining approaches, they recognize the growth opportunities that Erfan describes. Some might not even see JEDI as a trojan horse. Once you've mined your life experience for twists, turns, and defining moments related to JEDI, the value of this exploration for development becomes apparent. With this in mind, it's worth summarizing the stretch moves Erfan highlights: Illuminating the ways action-logics act on JEDI and on each other. Explaining why well-meaning people botch things up and get on each other's backs for doing so – but aren't destined to. Demonstrating how to simultaneously embrace a person or worldview *and* nudge it to stretch. And committing to the possibility that our actions, skillful and clumsy, resolute and restrained, virtuous and imperfect, might just bring more justice, equity, diversity and inclusion to the world within and around us.

Don't Criticize. Supplement.

Having outlined the contributions this paper makes to both JEDI and adult development, I now offer what I call a "supplemental perspective." This is based on the premise that if you want to expand a picture of reality to include more of what's good, true, and beautiful, don't criticize. Supplement. Don't shout, *Look at these imperfections*! Ask, *What if we were to supplement these ideas with others? Might we find new vistas in this integrated mesh?*[10]

More JEDI Faces Require a Bigger Tent – A Supplemental Perspective

Erfan's core premise is that we're more likely to realize the aims of JEDI if we honor how every action-logic relates to these aims and can contribute to their fulfillment. This is the "many faces" vision. As I reflect on the specific aims she describes, I notice myself yearning to expand them. This expansion seems important because the existing aims, at least as described in this paper, seem primarily an expression of the Redefining action-logic. They are about including marginalized groups and reflecting on your own complicity in their exclusion (assuming you are not among the marginalized yourself). These are essential, yet I think we can aim more broadly. In particular, I wonder how the Transforming action-logic might approach this challenge. Not only by using its capacities to pursue what I'm calling Redefining goals, but to reimagine what the goals of JEDI might be. Given Transforming's access to polarity thinking, a systems view, and many other dimensions of complexity, what aspirations for JEDI are possible and enlivening? Here I see an opportunity to expand beyond the picture Erfan paints.

---

[10] For three other examples of this, see my *two-part series* on the book White Fragility, *this effort* to understand what makes Mr. Trump tick through both his Enneagram type and action-logic, and *my prior article* in this journal, Nine Paths of Growth: Integrating Immunity to Change with the Enneagram.

At Transforming, Erfan writes, “I use my power to create spaciousness and amplify the voices of those who have been on the margins – then create careful space for the voices of dominant groups, too.” This is wise and necessary. Yet does it represent the full potential of the JEDI project? Or even the most that Transforming could make of JEDI’s intentions? The central intent in this statement and, it seems, in Erfan’s overall conception of JEDI, is to is help “marginalized” people gain more voice and help “dominant” groups reflect on how they might support this more effectively. Again, these are essential aims. What if we were to supplement them with others?

My engagement in the JEDI conversation, tracing back to my days as a college student, has largely been around “race,”[11] specifically in the United States. It is in this arena and geographic focus that I have given JEDI the most thought and am most inclined to wrestle with the past and reimagine the future. In the past few years, my own stance on “race” in the United States has undergone a substantial revisioning and expansion. I feel just as strongly about including more voices in organizations, supporting Black American leaders, reforming criminal justice, reducing wealth inequality, and improving health and educational opportunities. It’s important to me that all of us have equal opportunities to prosper and, more foundationally, to live a minimally decent life.[12] At the same time, I’ve observed that these aims, when not connected broader a humanizing vision, feel incomplete and are easily thwarted by other interpersonal and cultural dynamics.

How Big Aims Get Thwarted

Two such dynamics stand out: The inclination to define myself as a “rescuer” and the powerful pull of the antiracism discourse toward guilt and resentment. Let’s start with the rescuer. As long as I position myself as purely an advocate for others’ interests – whether by combating systemic racism or making myself trustable by coming clean with my complicity – and don’t stand in my own interests, I am at risk of becoming a rescuer. My job in this role is to protect “victims” from their “persecutors.”[13] This has serious downsides: It is condescending. It dehumanizes the people I’m helping and the ones I’m protecting them from, because it’s hard to see them beyond these roles. And, most subtly, it dehumanizes myself. My virtues, flaws, yearnings, interests, and dreams get shrink-wrapped into a narrow motivation to be others’ ally. (Note: In case it’s not apparent, I’m not attributing any of this to Erfan, but instead to the way my sense of self shifts when adhering to specific aims without an aspirational vision).

---

[11] In the United States, we use the word “race” in many different ways. Here when I say “race,” I’m referring to what I call Race as Topic – a short-hand way of summarizing a variety of conversations related to what in the past went by other names like “the color line.” I’m not referring here to Race as Biological Classification, a concept that below I assess to be meaningless genetically and harmful. Nor to Race as Culture – like when the word “Black” means not a biological race but a cultural group with similar ancestry like Black Americans. I’m currently writing a paper that explores all of this in more detail.

[12] In a minimally decent life, girls and boys go to school with food in their stomachs. When sick, they have access to a primary care doctor and a way to get there. This is not about economic equality. It’s about creating a “floor” of decency and dignity.

[13] This is a reference to the drama triangle (victim/rescuer/persecutor) model of dysfunctional interpersonal dynamics described by Stephen Karpman.

Things become even stickier when pursuing my long-held aims in the midst of today's discourse around antiracism. I've written at length about this elsewhere[14] and am here to supplement, not critique. Suffice it to say that this discourse tends to evoke in me either guilt or resentment. Each of these is a mood, defined here as a persistent emotional state and assessment that creates a particular predisposition to action. This differs from the common conception of moods as short-lived, as in "I was feeling down, but then I found a twenty-dollar bill on the ground, and my mood improved." In my definition, a mood has staying power. If emotions are like the weather, constantly changing, moods are like the climate (at least our experience of it prior to climate change), persistent over months and years. Within the family of moods, guilt is the assessment that "I've done something to harm you and can never make it better." It predisposes me to apologize (important and useful when sincere, but harmful as a habit) and even self-flagellate. When stuck in a mood of guilt around racism, whether systemic or individual, exterior or interior, I may feel like a "good" person doing noble work. But my actions get distorted and my own sense of dignity shrinks. This is not an ingredient for constructive action. And, like every mood, guilt is contagious. Hence the shared mood of guilt that can arise in particular anti-racist forums.

The mood of resentment operates similarly but in the inverse. Here the assessments are "You've done something to harm me and can never make it better" and "If you've been harmed, it's because you deserve it." My instinct here is to punish others. I might react to the slightest remark by another person to accuse them of "centering white people." Or, to put myself in another perspective, of accusing everyone of being racist. The actions that resentment conditions me to take aren't constructive. And, like guilt, resentment is contagious.[15]

Why these dynamics matter is that they thwart me in pursuing heartfelt intentions like including marginalized voices, reducing police violence, and increasing Black American prosperity. It's as though these intentions get gobbled up, distorted, or squeezed of juice (pick your metaphor) by the overpowering force of the rescuer role and these two de-energizing moods. It's not an even fight. What's missing are aspirational aims with the power to do two things: first, expand my role beyond that of the rescuer (if not beyond the very notion of roles), and, second, shift my mood to one more conducive than guilt and resentment to timely and effective action.

Moving Beyond the Rescuer Role

Let's start again with the rescuer role. Growing beyond this is possible when I inhabit stories in which I am not a side player serving as an "ally" but a central protagonist. This does not refer to the classic individualistic (male) hero who battles dragons and returns home with a chalice (though that tale has its time and place). Instead, this is more akin to how my colleague, Jewel Kinch-Thomas, describes the heroine's journey. It is a journey we take together. We are all protagonists with virtues, flaws, and aspirations. And we engage in it for a collective purpose larger than – but including! – ourselves. This is self-interest writ large. I am unabashed about my narrow interest, whether it's to make friends, earn a living, or feel good about myself. (Long live the Opportunist and Diplomat and…). I also claim a broader interest – to support my community, organization, family, and tribe. And an even broader interest, like serving humanity. The energetic force of being part of a story like this makes the rescuer role look modest indeed.

---

[14] See my two-parts series on White Fragility cited above.
[15] Guilt and resentment also reinforce and are recapitulated by the drama triangle.

Shifting from Guilt and Resentment to Energizing Moods

A second attribute that makes an aspirational aim worth pursuing is that it shifts me out of guilt and resentment. Here we can choose from (not that this is all conscious choice!) several alternative moods that are more energizing. One is a mood of ambition, here defined not as the desire for success but the assessment that "We can do this." Or perhaps it evokes in me a mood of wonder, where "The future is uncertain, and I'm curious how things will turn out." Or acceptance, where, even as I long for a better future, I accept the brutal facts of today. Acceptance may sound passive, but it isn't, particularly when coupled with ambition. The civil rights movement in the United States was arguably grounded in a combination of acceptance and ambition. Think of the restaurant sit-ins in Greensboro, North Carolina, or the children who walked through mobs to integrate schools. We're in the terrain of what Albert Murray called "stomping the blues." We respond to misery and uncertainty not by fighting or collapsing but with "dance-beat elegance … which is to state with your total physical being an affirmative attitude toward the sheer fact of existence." I'm also reminded of the "tragi-comic" attitude toward life that Ralph Ellison tied to the Black American experience. As Ellison wrote, "This has been the heritage of a people who for hundreds of years could not celebrate birth or dignify death, and whose need to live despite the dehumanizing pressures of slavery developed an endless capacity for laughing at their painful experiences." In this sense, insisting on alternatives to guilt and resentment honors and is rooted in the Black American experience.

With these criteria for an effective aim in mind, let's turn now to the task of creating a bigger tent for JEDI's many faces. What might be aspirational aims for JEDI in the context of "race" that move us beyond the rescuer role and evoke affirmative moods? Here are three that in recent years I've learned to take seriously and now propose for your consideration.

Aim #1: Embrace Each Other's Humanity

As a nominally "white" man, what if I were to focus my attention on appreciating the full humanity of Black Americans[16] (and others – but let's stick with this simplified picture)? This means not only how they've been excluded and injured, but also how they are as fully human and fully American as me, in all the complexity that these terms entail. Let's say I focused like a laser beam on this challenge. What new conversations would I engage in? How would I listen differently in the conversations I'm already in? What new commitments would I make – and what old commitments would I sever? What new books would I read and podcasts would I listen to??

Humanizing someone is fundamentally different from the tracking all the ways they've been dehumanized (and excluded and harmed). It is a reconstructive project. As such, it's more intriguing to me and more likely to call on my deepest virtues and curiosities than the exploration of exclusion, which is often deconstructive in form and intent. In fact, what better way is there to truly include another person than to see them as fully human as myself? To clarify, this is not "we are all one."[17] This is "we are all human," with all the difference and sameness conveyed by that term. As my colleague, Greg Thomas, has taught me, if you want to honor the full humanity of Black Americans, focusing exclusively on their marginalization and your contribution to that marginalization doesn't accomplish the task. On the contrary, it can be demeaning, because it excludes most of what makes Black Americans human beings. This means their agency, personal virtues and capacities, and expression of the highest civic ideals. It also includes their dreams, curiosities, life experience, flaws, temptations, and foibles. When you take seriously someone's full humanity, the idea that they are defined by their exclusion, however persistent and painful, seems inaccurate, if not patronizing.

---

[16] Here I use the term Black Americans to refer to a cultural group, not a racial category. The word "black" is too closely tied to the notion of "race." Also, the cultural practices, vernacular speech, and physical movement of Black Americans is very different from those of people with similar amounts of melanin but from, say, Nigeria or Grenada.

A good example is how we talk about Black Americans' place in the United States. The Redefining action-logic often speaks of Black Americans as being outside of and separate from "white" American history and culture. This assessment is well grounded with regards to political and economic exclusion but completely off base in terms of culture. From music and art to dress and language, there is no American culture without Black American culture. The latter has so deeply influenced the former that it's simply inaccurate to speak of them as separate. From this vantage point, Aretha Franklin and Stevie Wonder aren't just legendary Black American musical artists I admire. They're human beings whose music, style, and creativity has infused my own. Cultural ancestors of mine, to be sure. You could call this antiracism, but it's really more about E Pluribus Unum – out of many, one.

If you think about it, democracy in the United States also wouldn't be what it is today without Black Americans. Just consider the subtitle of Martha Jones's book *Vanguard*: *How Black Women Broke Barriers, Won the Vote, and Insisted on Equality for All*. This is the story of women who were marginalized three times over: by nominally "white" women in the suffragette movement, Black American men in the church, and millions of "white" Americans in the struggle for civil rights. And yet they persevered with courage and ingenuity – along with moods of acceptance and ambition – to advance the country closer to the ideals of its founding documents: the Declaration of Independence, Constitution, and Bill of Rights. This interpretation of history neither sweeps suffering under the rug nor enshrines it as a defining trait of a people. Instead it's a testament to the country's contradictions and imperfections and capacity to wrestle with them.

We can also tap into the notion of "rooted cosmopolitanism." As articulated by the philosophers, Anthony Appiah and Danielle Allen, this is the vision of being rooted in a local, vernacular culture while simultaneously identifying as a citizen of the world. It provides an alternative to the particularism of identity groups (whether marginalized or "blood and soil ethno-nationalists" and the universal sensibility of feeling equally comfortable everywhere. Rooted cosmopolitanism embraces the polarity between these interdependent opposites. In the realm of JEDI, it is unity within diversity. I see and appreciate your difference from me. I also am curious about what makes us similar. Making such declarations isn't ignoring economic exclusion, police violence, or inequalities in the criminal justice system. It's saying that I care about you because part of you is inside of me.

---

[17] A sentiment, according to Erfan, that the Achiever action-logic often holds.

Embracing each other's humanity through any of these paths feels more expansive and attractive to me than the aims of including marginalized groups or combating racism. You can be pro-inclusion and antiracism without necessarily humanizing folks. But it's hard, I think, to see another's full humanity and then not want to embrace their voices and create social and political structures that welcome them. In this aspiration, the rescuer doesn't get much traction, and we experience moments of shame and anger rather than persistent moods of resentment and guilt.

Aim #2: Deconstruct Race

Perhaps it's time to use our Redefining powers to deconstruct a concept that for centuries has remained untouched despite its destructive impact: Biological race as a category for classifying human groups. In writing these words, I'm crossing a line of taboo. Tracking people by racial categories allows us to quantify important data like who's suffering disproportionately from Covid or sickle cell anemia or who's more likely to be incarcerated for the same offense, like crack vs cocaine.[18] Take away those Census Bureau classifications, and the antiracism project might as well be dead. Or so we assume.[19] As importantly, many Black Americans and their allies are committed to reconstructing race. Instead of *we're a different race that is inferior to you*, it becomes *we're a different race that is equal to you and special in its own ways.*

In this context, deconstructing race can feel like going out on a limb. Yet it is a worthy aim. What we call "race" may sound innocuous (look at all the official institutions that ask me to check the box), but it has little to commend itself and is the cause of great harm. It is biologically and genetically meaningless,[20] was invented to justify chattel (personal property for life) slavery and keep poor folks with different ancestral origins from rebelling,[21] and is a driving force today in the "white power"[22] movement. The concept of "race" doesn't by itself produce racism, but it is central to the ideology of proud racists as well as the unconscious habits of everyone else. It even sneaks into our conversations as ways of rationalizing racism itself. Karen and Barbara Fields refer to this as “racecraft.” When we say, “A police officer shot an African American man because of his race” or “the company excluded people from hiring interviews because they are Black,” we are attributing these actions not to the habits of the offender but to the “race” of the target. As the Fields’s write, racecraft “highlights the ability of pre- or non-scientific modes of thought to hijack the minds of the scientifically literate.”

---

[18] In the United States, the penalties for possessing crack cocaine, used more by Black Americans, have long been far more severe than the penalties for possessing powder cocaine, which is more tied with "whites"

[19] In *The Arc of a Bad Idea*, a book about deracialization, Carlos Hoyt proposes an elegant solution: have the U.S. Census (and other institutions that collect such data) ask people not for their race (as objective fact) but instead as how other people identify them. In other words, to switch the language of these categories from race to racial identity, from fact to interpretation.

[20] According to scientists, each of us shares 99.9 percent of our genetic material with every other human; the genes that code for skin color and facial features code for little to nothing else; and there is enormous variation in skin color on the African continent, including variants for light pigments also found in European ancestry.

[21] In the 1670s, the colony of Virginia created laws that distinguished "white" people and "black" people, at a time when using "white" to describe skin color was only five years old. This happened after "white" indentured servants and "black" indentured servants and slaves united to rise up with arms against plantation owners, an event known as Bacon's Rebellion.

[22] A term that the historian, Kathleen Belew, among others, uses to describe the mix of white supremacist ideology and apocalyptic thinking. As evidenced in the January 6 attack on the U.S. Capitol, this is a violent movement whose collective mood is at times both resentful and euphoric.

Deconstructing race, coupled with humanizing each other, meets our two criteria for aspirational aims. It is invites us into a heroine’s journey rather than into the role of rescuer. We are jointly unlearning habits that we jointly learned together without knowing it. When coupled with humanizing others, it steers us away from moods of guilt and resentment and toward acceptance and ambition.

If our reckoning with racism is long overdue, so too is our jettisoning of the ideology of “race” that buttresses it. Could this serve as an additional aim of JEDI and antiracism work? Even if we accept that this is a mighty undertaking that could take a generation or more to realize, consider how powerful and freeing it feels to stand for this vision of shared humanity.

The journey, of course, starts with each of us.

Aim #3: Reclaim Our Humanity by Deracializing Ourselves

In a related vein, I’d love to see later stage folks of every hue take on the following transformative JEDI project: Deracializing ourselves. This is the individual corollary to the collective project of deconstructing race. As envisioned by Carlos Hoyt in *The Arc of a Bad Idea*, deracialization means undoing a lifetime habit of calling myself “white,” my neighbor down the street “brown,” and my business colleagues “black.” I may be *identified* as “white.” My neighbor may be *marked* as “brown.” And my colleagues might be *nominally* “black.” But these are terms of interpretation rather than assertions of essential nature. They acknowledge racial identity, which is real (and will remain so as long as most of us reify race), while also granting people the complexity and individuality that is their due. Instead of just decrying racism and my own complicity in it (or privileging from it), this involves refashioning the very way I identify myself. For the Redefining action-logic within me, such attention to language and power dynamics is appealing. Yet it runs up against a more complex task: Reconciling deracialization with my own commitment to antiracism. How can I combat something that I claim does not exist?

The answer, of course, is that this is a false choice. Just because most people falsely believe in race, and some of these people use the ideology of race to justify racism, doesn’t mean I need to do the same. I can recognize and see the pitfalls of others’ habits without falling into them myself. In other words, there is nothing contradictory in the notion of an anti-race anti-racist.[23] If this sounds complex, that’s because it requires me to take multiple perspectives at once: What’s objectively true, what I see about this, what others see about this, and what others see that I see about this. Not easy!

---

[23] I’m aware that this term is a doubling down on a deconstructive stance. Oops.

Fortunately, with a bit of reframing, this becomes an opportunity to call forth (or be pulled by) the Transforming action-logic. As an exercise, I might journal about early life experiences when I internalized my racial identity as objective fact – and how this identification with a particular race shifted as I grew through the action-logics. As an ongoing reflection, I might pay attention to all the ways I and others recapitulate racial essentialism in our words and actions. As a practice, I might introduce terms like *nominally* and *identified as* when referring to anyone's (false albeit socially acceptable) racial category. Here, as with other JEDI endeavors, I can "bring everything I have – theory, data, truth-telling, charm, humour."

As a growth challenge, deracialization carries two additional benefits. First, it is not intrinsically built to induce a mood of guilt. Learning how I've become identified as "white" carries less moral tone than learning how I've been complicit in systemic racism. Both projects are important. However, whereas the latter predisposes many action-logics to guilt, the former sparks curiosity and a mood of acceptance. Second, the language I practice and the reflections I undertake in deracializing myself are not about rescuing. They are about reclaiming my and others' humanity. I have skin in the game.

Conclusion

I am inspired by Erfan's "many faces" approach to JEDI and wish to see it succeed. Given the ways it can be thwarted, I propose we build an even larger tent of aspirational aims. Let's remake JEDI as a transformational journey, and let's do so by including a multitude of enticing motivations, practices, and paths. Come, if you must, to interrogate your complicity, but stay for the deracialization and humanization.

A Promethean Mission:
An Update on the Prometheus Leadership Framework

Thomas Bohinc[1]

In August 2020, three researchers published our article on a leadership framework 1.0[2] for the purpose of opening more collaboration toward the objective of a framework to help navigate the complexity of leaders and leading.

Over the 16 months since Jonathan Reams, Richard Claydon and I published our opening paper, we have continued the very efforts that were intended as follow up.[3]

It is hard to overstate my appreciation for those that gave us their time and shared our curiosity. The opportunities we create to listen with an open mind and accept disconfirming and reforming experience are too rare. They take time. They take mindsets, hearts and purpose greater than building our academic credentials or our brand and followers.

What we have learned has evolved some of the framework content but has mostly provided refinements and clarifications. This article is an update on all of that.

Just an Organizing Principle

The 2020 paper noted the choice to organize around what we saw that as the highest purpose of the Prometheus Leadership Commons framework (the “framework”) and The Prometheus Project.

There were two complementary criteria. The first was supporting this generally approachable narrative: “a leader brings who they are and what they know to the action-choice of leading so that they can have what they want” (see figure 2). The second criteria was organizing the framework as learning objectives – or a system of capacities and capabilities that we have in mind for leaders.

---

[1] **Tom Bohinc**, MBA, is a business executive and consultant turned leadership coach and independent researcher. Tom’s experiences leading business transformation in global organizations and close work with product and operational teams crystalized his focus on human factors, leadership coaching and leadership development practices over the last 15 years. Tom’s observations the from the Conscious Capitalism Conference in Barcelona, 2018 sparked The Prometheus Project.
tjbohinc@gmail.com

[2] https://integral-review.org/the-prometheus-leadership-commons-a-meta-framework-for-leadership-and-leadership-development/

[3] Since then, many hundreds of hours of conversations, forums, panels, and focus groups have been done around the topics in the framework. CEOs and Chief Learning Officers, mid-level executives, front-line leaders, community leaders, coaches, consultants and esteemed academics representing global mega-brands, distinguished university faculty, small and start-ups, and NGOs have contributed from four continent, each with a part of the puzzle that tests the clarity and energy of who leaders are, what they know, and what leaders do.

SOME RIGHTS RESERVED

The framework's primary structures remain sets of affective, cognitive and behavioral objectives that make up who leaders are, what they know and what they do. However, in these months of engagement, we found the idea of learning objectives is not as familiar a concept as we assumed it would be. The short description of learning objectives is that they are the observable or measurable outcomes that are the goal of any of the learning methods (materials and activities) that are employed.

An example is an element in the framework's *objectives* of self-awareness and empathetic awareness of emotions. The framework is not saying (with this element) that the *method* to build leadership is through doing self-reflection or empathy. The framework is listing those elements as outcomes that are part of the system or capacities of a leader. The *method* to build that emotional consciousness may include any creative mix of methods including knowledge of theory, experience, socialization, experiment, action and, yes, inner reflection.[4]

Learning and Development Structures

Since we noticed this tension about objectives (outcomes) vs methods (actions), we also noticed the tension was nearly unavoidable. In retrospect, this is reasonable that raising one begs the question of the other. So, we chose a pivot. Better to show both dimensions (objectives and methods), so that both were available in context, than to present one and still have to clarify both.

Therefore, in the framework each of the meta-domains of Being, Knowing, and Doing now includes a "How To" meta-structure that supports good conversation around learning and developing for that set of learning objectives. Thus, in details of The Prometheus Leadership Commons 2.1 framework you will find a set of attributes organized for learning objectives AND sets of practices for how to develop those attributes.[5]

For example, the *cognitive* meta-domain of Knowing has an advanced *cognitive unconscious competence* as a high objective. However, mastery is gained by learning opportunities that include experience, socialization, affect and psychological integration. The *primary* objective is cognitive, but the *supporting* objectives (or supporting key results[6]) are a mix of cognitive, affective and behavioral.

Similarly, the *affective* meta-domain of Being has *psychological and emotional integration* as its advanced objective – but it is still gained by learning opportunities including cognitive models, concepts, experience, consciousness, action-learning, social sharing, and personal introspection.

[4] Reams, Jonathan; Bohinc, Tom; Roux, Marianne; Allen, Scott T.; Riggio, Ron; Sendjaya, Sen. New Intersections in Leadership Development Programming. International Leadership Association annual conference *Reimagining Leadership Together* Oct 20-23 Geneva, Switzerland.

[5] We could have abstracted one set of learning method attributes. After all, is learning and development materially different from one domain to the other? However, we found communication value in showing specific language and sequencing toward the primary objective for each meta-domain. One for Being, one for Knowing and one for Doing.

[6] We humans have a habit of thinking objectives can be single dimensional but then we remember that the more systemic they are, the more often they are complicated or complex system of objectives. This is the idea behind "OKRs' – primary objectives are met through a series of supporting objectives.

The Challenges of Language

One of the biggest areas of our learning has been around language.

We strived to have simple language that avoids simplistic interpretations. We tested terms that were as free from bias and jargon as we can make them. We dream of language that suits the specificity of researchers, the ease of everyday front-line leaders, and manages to avoid the tropes of populist influencers. We want to be inspiring and coldly realistic. Empirical and theoretical. But we have a constraint of one or two words per meta-domain, domain or sub-area.

We naively assumed that the experience of applying the framework would, eventually, lead to ‘the right one word.’ Instead, we have found that the underlying meanings are rich enough that one word (or a few) are more the choice for *a better* fit – or a *useful* choice among imperfect options. Any words we use that are good enough to open a topic must still be further clarified.

We also tried more poetic words that connoted the whole underlying meaning of a given subdomain. We tried words like beauty, clarity, love, wisdom, energy because they held deep value, but they were also so abstracted that few would find them accessible. We found a lot of blank stares. Instead, we have settled on the opposite approach – to pick the simplest prosaic words and let the rest come out in follow-up. We want words that invite inquiry. We do not want words that merely satisfy with inspiration.

Eventually, we took comfort in the reality of this and included some space for aliases in parts of the framework.

There is No Language Without Sufficient Experience

We also recognized language as a structural challenge.

Leaders and leading is not familiar to enough to our first-person consciousness and experiences to support adequate language. The right terms do not exist because our experience is rooted in one flawed reality but not an ideal reality – where leading is clear and leaders are common. Our language supports the current state because language is a system of the current state. Our language does not support the better state. We have to choose the words and hope for a day when leading is clear and leading is common *and then* find there is language *for that* experience.

We have to make do. We have to build the new.

Making do and building new is not so easy.

The Tragedy of Lists

The framework is a set of lists and a hierarchy of topics. That brings limitations. Any hierarchy is one-dimensional, which is an imperfect match for our multi-dimensional reality. We've settled on living with that, too.[7]

A case in point is the domain of leader Exchange Skills. What the framework lists are the contexts that skills are used in. We open a question like this: What skills are most useful for us or best learned in this context?

The framework does not (yet) give those skills (mindsets and practices).

Given the choice of a contexts list or a list of topics, we prefer the contexts – in order that we can choose topics that will be learned and used in that context, which is the best scenario for learning through action and integration.

We also find that topics are not so clear when they are out of context. Out of context, we accept more vagueness and theory and less practice and action. So, we choose the contexts as the primary organization because they also lead to more clarity on the skills.

Should we create a list of topics, as well? We think so. We have done some of that work. There is more to do.

Lists vs Sequences

This sets up one of the other limitations of lists – the assumption of sequencing. If there are a list of six things that are numbered or lettered, it's hard not to think of them as sequenced.

The framework identifies seven domains of leadership learning and tags them ABC and WXYZ. ABC are about who the leader is. WXYZ are about what the leader knows and does. These are just tags for quick reference in conversation even as they convey the 'two sides' of leadership as the leader vs the work and action of leading. However, there is no intention to convey a sequence or priority. You can start to learn with X or start with C or any other. [8]

At the third level in the framework, within seven domains, there are 38 sub-areas. Here, we *sometimes* intend to show sequence or hierarchy and sometimes we do not. Where we think there is a sequence, we find a way to make that point – but the *list* of single words (or word pairs) that make up the framework's lists of domains and sub-domains do not *always* imply sequence or hierarchy.

---

[7] A future version may provide some solutions. We would like to someday build the relational models that satisfied these complexities as well as the next level of atomized detail.

[8] We actually think that starting with Z is a good idea, because it leads to more specific and individualized insights around ABC WXY, some parts of the Z domain are adoptable by everyone in every context, so it builds over time and creates cohesiveness in the culture.

The domain of Action of Leading is another example. Its list of six sub-areas are not the linear experience that the list sequence may imply. There is a sequential logic to some parts, but in real practice these are addressed more organically to the situation. The first items, to ‘frame’, may very well start the action as implied by its position at the start of the list. But you could also frame and re-frame often and at any point in the action. Likewise, the ‘attend’ action can be done continuously across the whole action, not at the end of the action because it is positioned last in the list (figure 4).

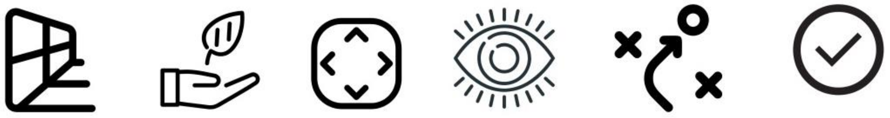
As far as our bias for attributing sequence and hierarchy to lists, as Cher’s character says in the 1988 comedy Moonstruck, “*Snap out of it!*”

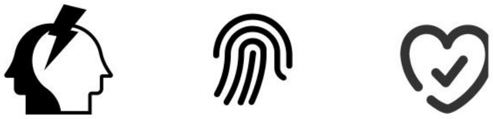
Metaphor and Symbol

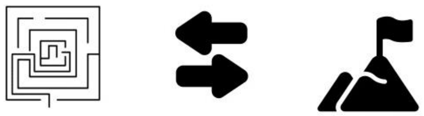
Because the words used in the framework are simple and inadequate, but the concepts are rich with depth and inter-relationships, we find that more meaning is conveyed and more conversation opens with images and symbols. Even though they are not as specific, they evoke a richer story.

We spent time these months creating and testing images and symbols for the seven domains, and the four to six sub-areas that are associated with each of them. We will continue to build symbolic content and welcome contributions in this area.

These are sets of symbols for the six sub-areas of the Action of Leading domain, the three icons for the domains within the Being meta-domain and the three icons for the domains within the Knowing meta-domain. These are examples. Come back to these and see if they help form a story of Leading, Leaders and Knowing for you.







Toxicity

We recognize our bias is to describe the whole-being of leaders with generative skills and who chose creative action. Our bias is that we think that leaders are good.

We had quite a period of debate about this. Is everything that we cover in the framework true of good leaders and bad leaders, as well? Does Hitler fit these attributes as well as Mandela? Should a leadership framework be neutral about ethics or morality? This was a tough question for us and we may not have fully satisfied ourselves with the answer.

For now, our check against ill-intended influence, power and charisma is in two parts. First, the system of the whole person's character, specifically, the leader's Outward Stance, or the leaders' capacities for what is outside their selves which we talk about in terms of care, love and good. Second is the assumption of leading as a collective experience, where there is attention to the persons, purpose, and process that are part of the Action of Leading.

We'd like to think the capacity for good, the presumptions of collective awareness, and the voices of stakeholders and contributors would be 'guardrails' for toxic leadership. But we acknowledge that has not worked in many cases. Someone can have the capacity to be outwardly focused but not use that capacity – they instead act selfishly or narcissistically. They can attend to a purpose that is ill gotten and attend manipulatively to the emotions and psychology of collaborators or followers.

Right now, we are uneasy with the moral and ethical neutrality of the framework and trust it is sufficient that those in the context will step up to what is right and good and not ceding power to the single leader.

One of the future efforts around the framework may be to articulate the 'don'ts' of leading, in contrast to our current emphasis of 'do's.' We hope that crystalizing the 'don'ts' will empower followers and contributors to be more aware and make influential adjustments.

Down Selecting for Cohorts or Classes of Learners

Finally, the framework is useful if it includes all of the possible objectives to consider for a leader and leading, *but it also has to allow us to down-select objectives and prioritize them*.

We have done some work on the idea of baselines for cohorts or classes in an organization. For example, we held a series of focus groups with very highly experienced functional and HR executives and asked: "What would the leadership attributes be for someone be over the first decade of a career?" We have some good insights from this. However, the idea of a step-down guide is still on our list for the future.

What are the Attributes in Framework Version 2.1? What has Changed?

We have already covered the addition of structures for "how to" build each of the three meta-domains (first level).

For the main attributes of the framework, we have more than one version of lists and graphics that represent the content. Figure 1 shows a mindmap version. The figure is too detailed to read, but it conveys the idea of three major meta-domain branches, an associated ‘how to’ branch and seven (lettered) domains that are grouped and broken into 38 sub-areas that have various other groupings and clusters. All of the branches are color-coded and some show associated icons.

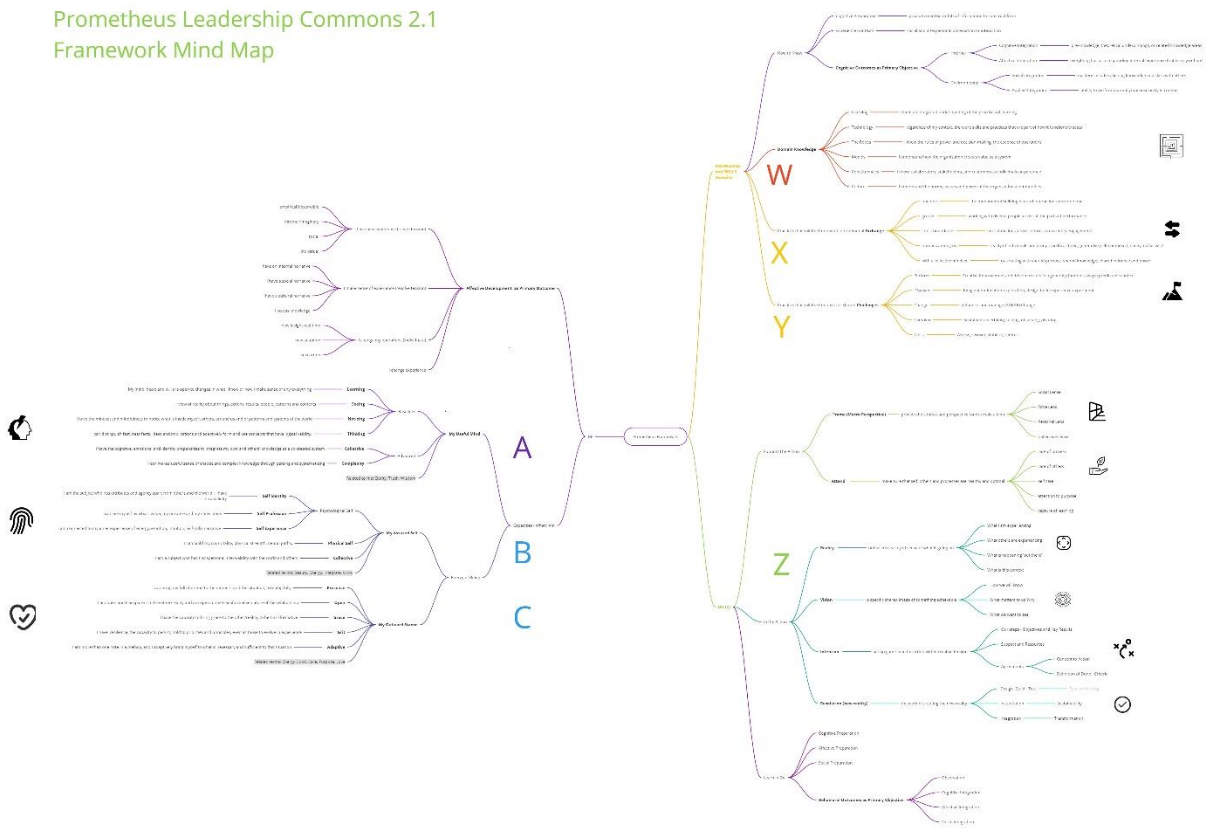


Figure 1. Mindmap of Prometheus Leadership Commons 2.1

What follows is a summary of framework changes and evolution.

Loosely Fixed Top-level Structure

We use variations at the top-level structure. I suppose that is counter to those who want a neater framework, but we think they all work together.

- The simplest is that we arrange the framework by the distinctions between the leader and the leading. (We used this singular approach for framework version 1.0 where we had one group of “inner capacities of the leader” and another as “adaptive capabilities”).
- We also use the (increasingly) familiar structures of being, knowing and doing (“Be, Know, Do”), and variations. These are very digestible and effectively open curiosity and conversation around who leaders are and what leading is.

- We make the distinction about the "Know" meta-domain as being both "knowledge and experience" and "practices and skills." When we say "Knowing" we mean all of this.

- Finally, including practices and skills in "Knowing" opens the view of the Action of Leading (or Doing) that we think is an important contribution.

So our top-level division is really a set of variations. We think this is just fine for approachability and usefulness.

The alternative, if we were very literal, would be three levels of abstractions before we drill down to the seven domains. This would be much too complicated! We are already too complicated. Simpler is better.

Figure 2 shows one high-level narrative across the three meta-domains. Figure 3 has the very simple domains along with the purpose of leadership (you create what you want), with the color-coding that we use in all the detail graphics.

Domain Knowledge Addition to the (Second) Mid-level

The 2.1 version of the framework expanded from six to seven domains. The primary content of the framework is these seven domains and the three ‘how to’ domains are there as ancillary references.

The new seventh domain, Domain Knowledge, is part of the Knowing meta-domain. Domain Knowledge has six sub-areas that further define the categories of knowledge and experience.

Graphic views of the Knowing meta-domain and all seven domains are in figures later in this article.

The Challenge of Anti-intellectualism

There are some in the leadership industry who will disagree with Domain Knowledge as an attribute of leadership. They have two arguments.

One argument is that those areas of knowledge do not describe something unique to leadership – so they are not leadership. This is a really interesting point. However, we are not trying to identify the thing that *uniquely* distinguishes leaders from people in general, or that distinguishes leadership behavior from other behavior. We are identifying all of the things that are valuable to lead (because they then are also valid objectives for learning and development).

We think that there is a lot of other content that does not self-identify as leadership, but is. So choosing attributes that are also used to describe other practices or disciplines is not a bad thing, it is the kind of integration that The Prometheus Project is working to. We sometimes say ‘it’s the whole elephant,’ referring to the fable of the blind men unable to perceive the whole of the elephant.

A second argument is something like “Our survey respondents do not mention anything like Domain Knowledge as a statistically differentiating factor.” This may be literally true, but logically and pragmatically false. Those same survey results point to attributes like trust and behaviors like mentoring. They may further say that trust includes confidence in judgement, or discernment, or competence. We have never seen someone appreciate a mentor when they have nothing to mentor about. We have never known someone to have good judgement or discern a situation or to show trustworthiness in competence when they do not have sufficient knowledge and experience in the situation or subject.

Our own research over the last months confirms this for us. When we are speaking to the head of Artificial Intelligence, a technical product team or a physicist, you can bet your paychecks that they expect and admire domain knowledge in their leaders. When we discuss executive development programs with CHROs, you can bet that includes cross-functional and cross-cultural experience.

If our expectations on the future of work and the human race includes advanced technologies, or if the social experiences of anti-facts and anti-science are a cultural trend, that should convince us that Domain Knowledge is part of the mix of who leaders are, what they know and how they lead.

We are also curious if the research population of corporate cultures of the 90’s (for example) might have outlived its relevance for more complex organizations and operations today. It would be hard to imagine that those who selected participants did not skew away from contributors who favored technology and science but were marginalized in the minds of the organizations’ research sponsors.

Lastly, there may be a structural selection bias in those attracted to the leadership industry. Those who hold uncertainty or disempowerment, or shame around their intellectual abilities or achievements, or who hold a stronger need for belonging and connection than achievement and change are influential and prominent in this space. The industry attracts people people.

We can find models, programs or proclamations that work, ideas, and people domains. We hear some assert that too much emphasis is put on work and results, so the leader is someone who focuses on the person. Others say, that leading is about results and requires the capacity to forget our own stake and gratification and to prioritize the mission. Others will point out that the creative pursuit of some situations is creating knowledge – the intellectual capacity *is the point* so it cannot be put aside in leadership.

We think all are true. All have to be present. There is no holistic leadership if the whole of the human experience is not included in our definitions of it. Just as with our individual clients – it is about the range and the balance.

Over-intellectualizing is not better or worse than over-introspection or action without reflection. If we are tempted one way or the other – we are stuck in our bias.

The Max-of-Five-Constraint

In early design of version 1.0 we arbitrarily chose to have a constraint: The domains could not be sub-divided into more than five sub-area attributes. Like most constraints, this forced our creativity. We had to let go of our long lists, re-conceptualize and consolidate the sea of terms and ideas and keep the list of sub-areas more digestible. It served us well. Five seemed like a small number.

Still, as we applied the framework in real situations and with real people, we adjusted. In a few cases, we found the effort needed to clarify the max-of-five-constraint was counter-productive. The complexity added to the communicating was more than the simplicity gained from the limits.

A clear example is in the domain for the Action of Leading. The changes from version 1.0 to 2.1 include new terms but also a sixth sub-area.

The Action of Leading domain shows the wider pattern of actions for what is going on in any act of leading. Specifically, the patterns include four core actions (reality, vision, intention, and resolution) which are sustained by two supporting actions (frame and attend).

For a long time, we tested with five terms, pivoting between the idea of vision and intention. What we really meant was that leading includes establishing and sustaining a creative tension between the current reality and the vision, designing a strategy of actions and criteria for resolving that tension, commitment to act and learn from the team/organization/individual, and to sustain action to results.

We struggled to keep the max-of-five-constraint. We tried many clever and suitable approaches in dozens of events, but in the end, what worked was just to say: vision, reality and intention as parts of the action of leading.

In Version 2.1 there are now 38 sub-areas and up to six per domain within the learning objectives portions of the framework, and the three ancillary “How To Domains” each add more. It is a lot to absorb.

One of the ways that we express suitability for this design is that the framework seems too simple for the underlying reality of leadership, but too complex to easily absorb at the detail levels. That seems like the “Goldilocks” balanced approach, *and* the reason the details, as sparse as they are, have two summary levels above them.

These categories are parsed in the lists, but integrated and inter-related in the reality. The ‘whole elephant,’ again.

The Action of Leading Domain

This Action of Leading domain is one of the central points of value in the framework. It is designed from a synthesis of models including those from business change, product development, creative arts, psychotherapy and anthropological studies of indigenous tribes. We see a common pattern of creating, changing and learning across all of these models/theories.

To us, this part of the framework is the forest among the proverbial trees. This is the view of what is going on that can guide all participants’ actions as well as leadership development. We think this is where learners meet the reality of each other, who they are and what they know and can do.

If our theory (and others’) is true that we lead with the people and skills *that we have* (not who/what we want), then the components of the action of leading are the most important thing to learn to evoke a culture of leaders and leading.

If the theory that we learn character, capacity and capability *in action* is true, then the attributes of the Action of Leading are where we understand reality, sharpen our vision of what to learn next, hone our people and work knowledge and skills. The action of leading is the crucible for the creation of something new in ourselves, our common collective.

Figure 4 shows a graphic of the content of the Action of Leading in the context of the other six domain titles. There is also more overview narrative later in this document.

Figure 4. Action of Leading

How Do You Down-select a Baseline for an Early Career Class?

We held a series of workshops and focus groups where we were able to make a preliminary general summary for what we heard experienced sponsors of leadership wanted to see in early career staff. Below is some of what we heard.

Ideally, at the point of entering an organization people should have a foundation in these qualities. They would be expected to further develop and learn over a first decade of experience, so that initial qualities are well established and the next wave of capacities have taken root.

What Capacities *of the Person*?

From our focus groups one statement that stands out was from the woman CEO and MIT graduate of a tech company. Her number one leadership attribute was ‘someone who *wants* to have responsibility – the desire to be accountable is in their DNA’.

I would not disagree with this. But it is a great example of an attribute of a person that is not easy to deconstruct and to build into a development program. It can be a criteria for selection. But the settings where the candidates are being prepared still have the challenge of deconstructing the contributing elements – so they can be developed.

Looking at just the meta-domains of Being you might target these areas for development:

- I want the intellectual capacity to see past my bias and see a situation realistically and to see the possibility for change.

- I want the self-possession to be open to risk-taking, seeing and accepting reality, and courageous to take action.

- I want the dedication to purpose and resilience to be integral to the persons motivation so that they sustain effort for creating value.

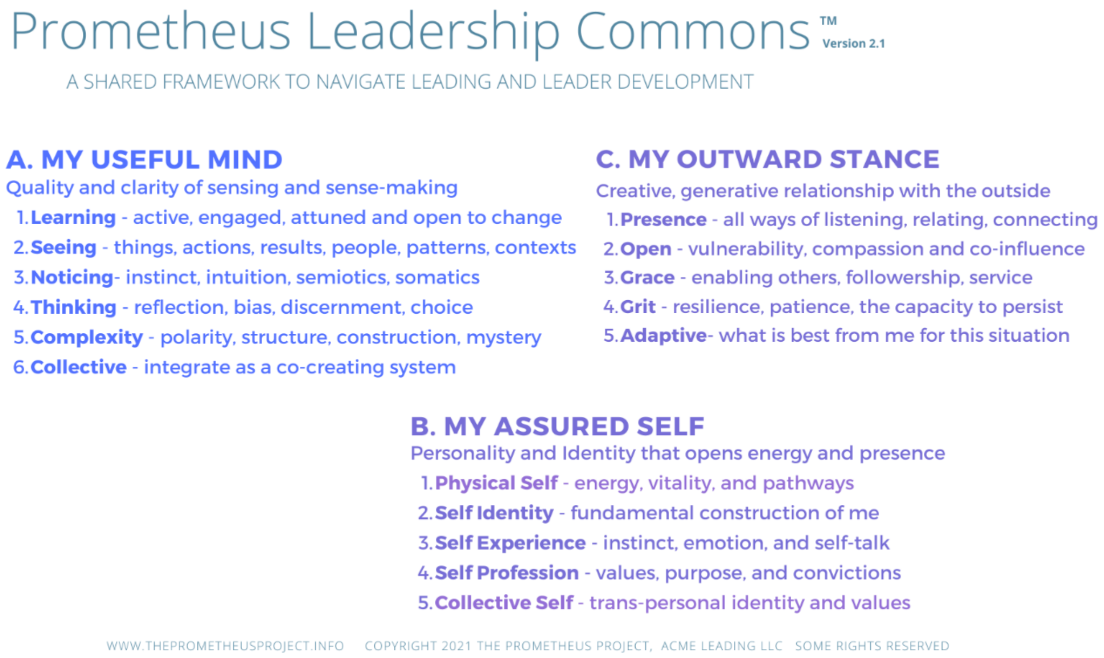
- I want the person to be comfortable with their emotional experience so that judgement is balanced and effort and motivation is sustainable.

Beyond this example, the focus groups highlighted other attributes of the leader (aka being) that said in many ways that the development of a person in this stage of career should include what adult development theorists would identify as having grown beyond an early stage identity.

These staff should have a sense of their own values, even as this continues to be formed in the new contexts and new experiences. They should have capacities that might be labeled empathy, service and kindness.

They should show the courage of their convictions *and* the openness to others' convictions and influence. They should have the emotional capacity and healthy identity to collaborate. They should have the self-possession to be open to the of constraints, authority and other actors.

Figure 5 shows the domain and sub-domains around the framework's Being meta-domain. Using the letters and numbers on the graphic, what we heard in the focus groups is that strengths should be present and built around A 1, 2 and, B, 1, 2 and 3, and C 2 and 4 as a priority for this first decade.



Prometheus Leadership Commons ™ Version 2.1

A SHARED FRAMEWORK TO NAVIGATE LEADING AND LEADER DEVELOPMENT

A. MY USEFUL MIND

Quality and clarity of sensing and sense-making

1. **Learning** - active, engaged, attuned and open to change
2. **Seeing** - things, actions, results, people, patterns, contexts
3. **Noticing**- instinct, intuition, semiotics, somatics
4. **Thinking** - reflection, bias, discernment, choice
5. **Complexity** - polarity, structure, construction, mystery
6. **Collective** - integrate as a co-creating system

C. MY OUTWARD STANCE

Creative, generative relationship with the outside

1. **Presence** - all ways of listening, relating, connecting
2. **Open** - vulnerability, compassion and co-influence
3. **Grace** - enabling others, followership, service
4. **Grit** - resilience, patience, the capacity to persist
5. **Adaptive**- what is best from me for this situation

B. MY ASSURED SELF

Personality and Identity that opens energy and presence

1. **Physical Self** - energy, vitality, and pathways
2. **Self Identity** - fundamental construction of me
3. **Self Experience** - instinct, emotion, and self-talk
4. **Self Profession** - values, purpose, and convictions
5. **Collective Self** - trans-personal identity and values

Figure 5. Being – the Capacities to Be

What Experience and Knowledge and Contextual Skills Do We Want?

The domain knowledge for leaders is not just the technical and market knowledge that is specific to organizations and roles. These are the things we traditionally expect universities to provide and will continue on the job. Other knowledge domains in the framework may be less conventional university content and even with a solid foundation of theory from schools, are ripe topics to continue to learn on the job. These include:

- An integrated understanding of the process and practices of continuous, collective, life-long experiential learning.

- “The Ropes” of how organizations make decisions and the cadence of their operations.

- In school we might learn the concepts of business models and value creation, but in the organization, we want to observe and understand what is specific in that organization, both in the present and in possibilities.

- Constituencies, groups of collaborators, stakeholders and customers as real persons in the organization’s political and social system.

- Culture is also a topic where foundational knowledge would support specific observation and strategies in the context of the norms, values and power of the organization.

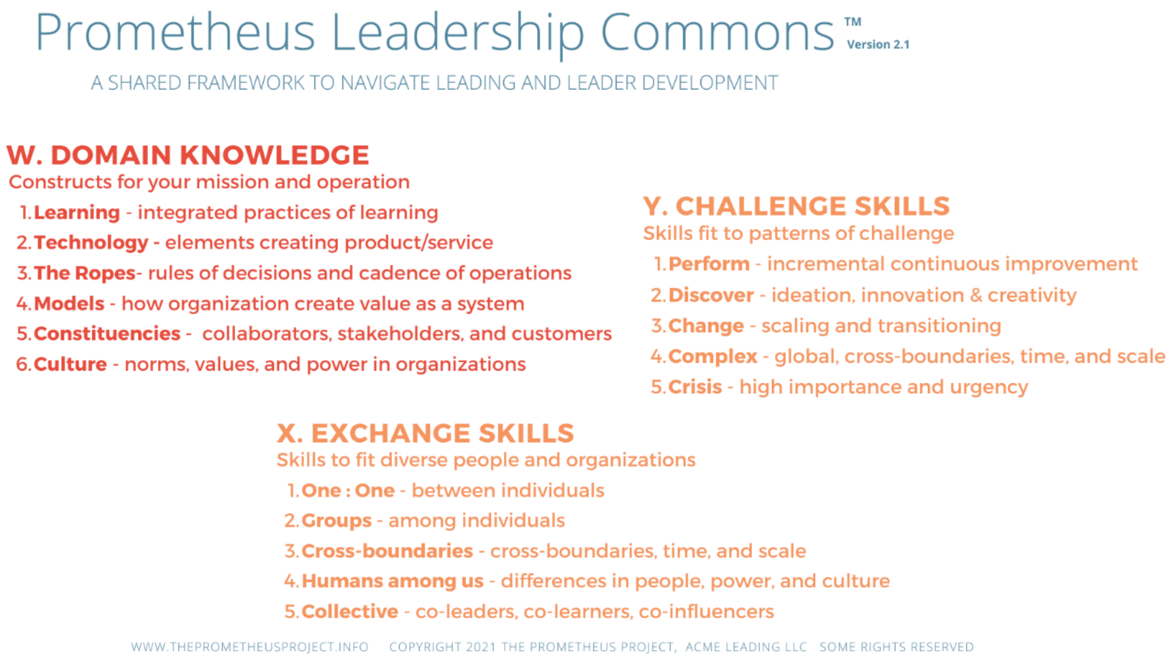
Moving from domain knowledge to skills and practices, what stands out is one-to-one and group communications and collaboration. Part of this is the capacity to work across multiple detail frames, from concrete to conceptual to general, as the basic skills of ‘communicating up and out’ beyond the immediate work groups and peers. These communication skills are not ‘once and done’ and are built upon and added to as time goes by and as responsibilities increase. For example, a new set of communication skills is needed for new managers who not only communicate laterally and up, but down and diagonally.

The work contexts and the skills should be mixed for both utility and learning. Whatever the situation they are in is the very best to learn those skills – because learning in action and learning in context trumps learning in theory or in the lab simulation every time.

So, what skills across the framework do we target? Some would argue that less experienced staff are most likely matched to more stable operations. So, the skills for incremental innovations, working from the perspectives of a team, contributor, leader and follower are useful. However, some roles may be more creative and innovative so ideation and co-creating skills would be appropriate right at the start.

It is safe to assume that most newer staff would not start out being responsible for leading in a crisis, or leading to scale changes across a larger organization, or leading globally or with unconventional relationships such as joint venture or tightly integrated channels. Even if someone were in those bigger situations, the skills they would need as pre-requisites likely include the one-to-one and group skills as a foundation.

Figure 6 shows the domain and sub-areas around the framework's Knowing meta-domain, or the capabilities of knowledge & experience and practices & skills. Using the letters and numbers on the graphic, what we heard in the focus groups is that strengths should be present and built around W 1, 3, 5 and 6, X 1 and 2, and Y 1 and 2 as a priority for this first decade.



Prometheus Leadership Commons ™ Version 2.1

A SHARED FRAMEWORK TO NAVIGATE LEADING AND LEADER DEVELOPMENT

W. DOMAIN KNOWLEDGE

Constructs for your mission and operation

1. **Learning** - integrated practices of learning
2. **Technology** - elements creating product/service
3. **The Ropes**- rules of decisions and cadence of operations
4. **Models** - how organization create value as a system
5. **Constituencies** - collaborators, stakeholders, and customers
6. **Culture** - norms, values, and power in organizations

Y. CHALLENGE SKILLS

Skills fit to patterns of challenge

1. **Perform** - incremental continuous improvement
2. **Discover** - ideation, innovation & creativity
3. **Change** - scaling and transitioning
4. **Complex** - global, cross-boundaries, time, and scale
5. **Crisis** - high importance and urgency

X. EXCHANGE SKILLS

Skills to fit diverse people and organizations

1. **One : One** - between individuals
2. **Groups** - among individuals
3. **Cross-boundaries** - cross-boundaries, time, and scale
4. **Humans among us** - differences in people, power, and culture
5. **Collective** - co-leaders, co-learners, co-influencers

Figure 6. Knowing Meta-domain

What Do We Want Them to Be Ready *to Do*?

Most of the focus groups would say that they want staff who understand how to take action, and adapt with agility as contributors, followers and co-leaders to serve the intention of the situation.

Anyone working with others to a goal will be more confident, focused and aligned with an understanding of "what is going on" in a general way, so that action is not lost in the details. That is the value of the framework's Action of Leading domain.

More senior members of the organization may typically want to take a front-and-center role in visioning, but the vision is not effective until it is internalized by the contributors. Ideally, a vision should be co-created and the idea of its place in the system ("this is what we will see when we are there") should be understood by all. The same goes for the other actions of being clear with reality, designing a strategy that all are committed to, and doing the technical or relationship work that creates the valued results. Every team member will want to understand the obligations and practices to "Attend" to the people and the processes they are engaged in. Teams that are self-managing and self-sustaining will need these capabilities.

One exception may be the function of "Framing," which is the perspective and larger context for the action. This is more likely the part for the more senior experienced members, rather than those in their early career. Senior leaders may want to Frame the vision that is created, so that how that vision fits into the larger context of the organization and its business is clear. Without that many visioning efforts flail. That said, Framing is a capability for leaders at every level. Certainly during that first decade all of these leaders will have the opportunity to initiate and oversee some sort of creative action where they are the Framers. Some will do this on day one.

Looking back to figure 4, what we heard in the focus groups is that strengths should be present and built around this domain would be Z 3, 5, and 6 as a priority, but there would be value and contribution in all of the sub-areas.

Flipping a Narrative

This is the image that I would like you to consider: If I gathered all the references and materials on leadership from academics, practitioners and programs, I would have two big piles and one small pile. The table would have a big stack around personal development and the inner experience of the leader. There would be a big pile around techniques and tools to use as a manager, team member or team. The third pile about what leaders actually do, that pile would be smallest. We would like to flip that story for learning and development. We will make leading clear and leaders common faster if we do this.

The action of leading, to us, is the most approachable, the most pragmatic, the shortest time-to-results and the shortest time-to-self-experience-as-a-leader. I think that the possibility at hand, the timely action, is to help people figure out that they are already capable leaders in some ways and to create a cohesive sense of what they are doing as a team so that they can discover themselves as collective leaders – self-managing, self-organizing, self-empowering innovators, creators, learners and makers of change.

The techniques and knowledge of the Know meta-domain will be valuable in some specialized or tougher contexts. The personal growth of the Being meta-domain will also be valuable, there is no reason to wait for that longer lead-time and there is no better way to crystalize and motivate people to change than their experience in the Action of Leading, today. So, as we have said a few times, lets us shift from preparing on the long-slope and to noticing the leading in action.

Future Interests

From Topics to Practices

The framework is a structure across all of the topics of leadership. It is a helpful tool to traverse and integrate the whole of the leadership story. This will help you set goals. This will challenge your assumptions.

The framework has always been a first step in the overall Prometheus Project’s mission of making leading clear and leaders common. What is needed in addition are insights into *practices* that are useful for leading. For example, one-to-one exchange skills include listening. What are good practices for a leader to adopt for listening? What are good practices for learning to listen?

This is not a shortcoming of the framework – it is unfinished business in the mission.

More Explicit Sequencing

There are indications in the newest framework about early vs advanced capabilities or capacities. Mostly, these are about contexts of greater scale or complexity. They are also about more collective consciousness, that are states of being consistent with adult development models.

However, additional details about dependencies and sequences would be helpful when actually applying the framework to an organization and its micro-learning and program design.

The "Promethepedia"

To support the specter of adding specific topics to the illustrate the categories in the framework, with growing content and relationships across content, we would imagine a Wikipedia-like resource that is collectively created and curated by a cross-disciplinary group through The Prometheus Project.

Down-select or Objectives Guide

We think that further experience with individuals and organizations to apply the framework to their specific contexts and vision will provide opportunities to form a rubric or guide for decision criteria about which objectives are suitable. We can see the potential for AI assisted software to support this process.

Clarity for Popular Concepts

There are many concepts and constructs in the popular engagement around leadership. Terms like 'emotional intelligence' are used with a presumption that that means something specific. We think it means a range of things across the framework. So, we would like to make popular concepts like this clearer by using the structure of the framework to parse and illustrate them.

Another is the concept of "empathy" or "trust." To build these requires meeting learning and development in several areas of the framework. If we are to progress past talking about leading and leaders and from abstractions to capacities, then some work is needed to parse and illustrate these kinds of outcomes.

More Explicit Integrations

There are valuable tools and models that have been considered in our research and are part of the experience we draw from. We think it would be helpful to articulate the relationships and the structure of the framework. The framework will meet its purpose when it can serve as a commons across all of the proprietary resources or provide a context for all of the atomized content and research.

Cross-sectional to Longitudinal

We would like to use the framework on a longitudinal basis to re-plan and govern an organization's leadership development policies and programs – across all functions and levels of an organization. We recognize that some organizations are increasingly virtual/fungible across legal entities such as co-producers and contractors. We'd like to extend the scope of leadership governance and development to the whole of those who are contributors and stakeholders.

Do's and Don'ts – Toxicity Rubric

As noted earlier, the framework is looking at the good leader's attributes, but one of those capacities of leaders is to assess the current reality they are in – including assessing when something is not right, wholesome or generative. Then, to find a creative, generative response, which may not be 'cancel culture'. We think more explicit content about the 'don'ts' of leading and creating will be helpful. We have opened a space in the www.WeLead.Gobal community as a placeholder and have taken a few initial steps toward this content.

Additional Voices and Influence

The voices of The Prometheus Project are substantial, but we would love to expand this. We would particularly value aligning more psychiatric, neurological and psychotherapeutic perspectives, more chief learning offices, like-minded practitioners and consultancies, and more individual leaders at front-line and middle levels.

Community of Purpose

The Prometheus Project holds a digital space for members who share the mission of making leading clear and leaders common. This can be found at www.WeLead.Global. Consumers and observers are welcome. But creators and contributors are needed to realize the vision for this space for inquiry.

Open Cautions

Feeding Perfectionism

All of these leadership attributes tend to push our assumptions to the point that we expect ALL of these attributes in our leaders. That will never be true (or rarely will be).

First, we remember that we think every single person in an organization, team or community has moments of choice and potential to lead in small and large ways. We want them to self-recognize these possibilities *and to be recognized* for these contributions.

Second, we have always held that leadership is a collective practice among imperfect leaders – not a heroic practice of one superhero. We are concerned that the scale of what is in the framework will convey unsuitability to someone who compares themselves to this system of leaders and leading. Almost no one will measure up. We do not want the message to be that they do not have the stuff because they will never be all of these things. Rather, this is the basket of possibilities for themselves and the mix of whole leadership that they can assemble as a team.

Third, this raises the complementary ideas of followership, kindness and flexibility among each other and with those in positions where leadership is expected. They may or may not have all of these qualities. They will not. Leading can happen imperfectly.

This is one of the reasons why focusing on the Action of Leading domain is a priority – to just know and expect what it means to lead in some shared purpose.

Feeding Exclusivity

Similar to perfection, we know that the demands of leadership are broader and more complex at higher levels of an organization. So, we might be reinforcing the idea that long-term leadership development should be focused on those at the top (or on their way).

We want those at the top to be great leaders.

We also want those everywhere to be great leaders in their contexts.

We think that focusing on the Action of Leading domain can help achieve this. Everyone can execute the components of this domain – even if they do them as imperfect people and with imperfect knowledge and skills**.**

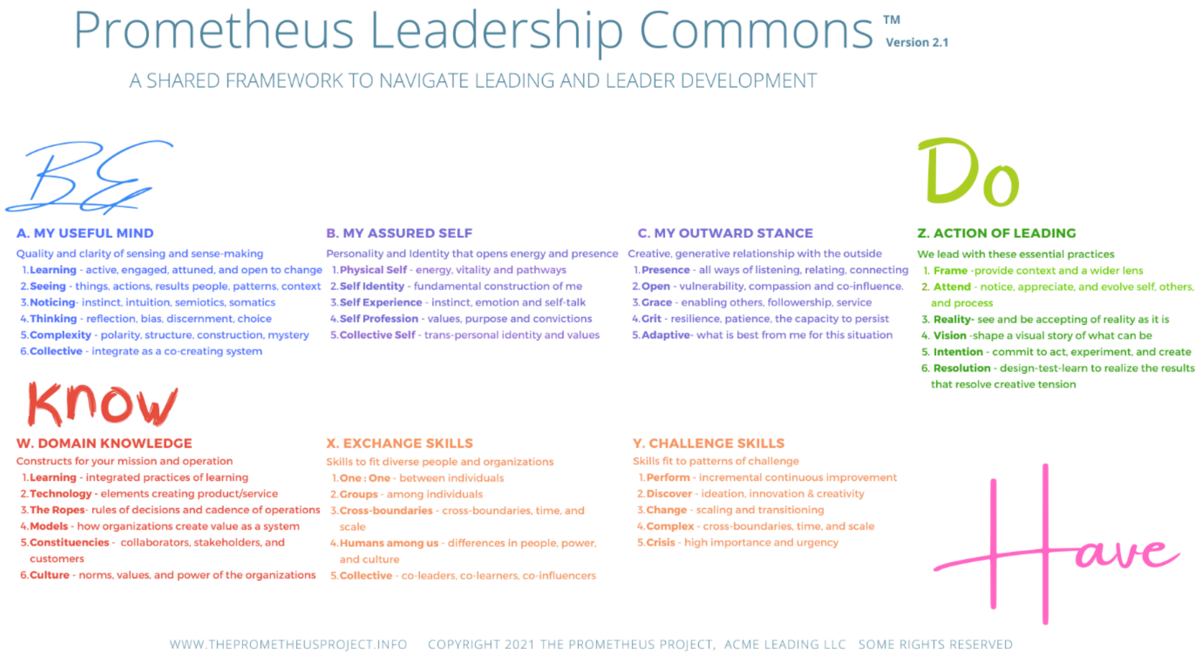
The Prometheus Leadership Commons 2.1 Summary

For reference, figure 7, shows all of the seven domains, grouped and color coded.

The Capacity to Be

The blue tones in the figure are the domain of Being (aka Capacity to Be) (aka The Leader). While this domain is about who we are, not what we know, there is a knowing component to persons. The brighter blue domain and sub-areas are about “What is going on in me so that I know?” or “What are the elements that I integrate to bring clarity and wisdom and consciousness about myself and the world?” The more purple tones are about me as the subject that is self-aware and me as the subject that is focused on what is outside of me, whether that is other people, principles or purpose.

When we are fully accepting and conscious of ourselves, we are beautiful and others are beautiful. We are filled with quiet power and energy. We are clear and unfiltered about all kinds of truth and wisdom. We may never be this whole or fully human, we may only have glimpses and moments of these states. If we are lucky and wise, we will leverage each other to meet this standard and accept and love our clumsy humanity as we go.



Prometheus Leadership Commons™ Version 2.1

A SHARED FRAMEWORK TO NAVIGATE LEADING AND LEADER DEVELOPMENT

A. MY USEFUL MIND
Quality and clarity of sensing and sense-making
1. **Learning** - active, engaged, attuned, and open to change
2. **Seeing** - things, actions, results people, patterns, context
3. **Noticing**- instinct, intuition, semiotics, somatics
4. **Thinking** - reflection, bias, discernment, choice
5. **Complexity** - polarity, structure, construction, mystery
6. **Collective** - integrate as a co-creating system

B. MY ASSURED SELF
Personality and Identity that opens energy and presence
1. **Physical Self** - energy, vitality and pathways
2. **Self Identity** - fundamental construction of me
3. **Self Experience** - instinct, emotion and self-talk
4. **Self Profession** - values, purpose and convictions
5. **Collective Self** - trans-personal identity and values

C. MY OUTWARD STANCE
Creative, generative relationship with the outside
1. **Presence** - all ways of listening, relating, connecting
2. **Open** - vulnerability, compassion and co-influence.
3. **Grace** - enabling others, followership, service
4. **Grit** - resilience, patience, the capacity to persist
5. **Adaptive**- what is best from me for this situation

Z. ACTION OF LEADING
We lead with these essential practices
1. **Frame** -provide context and a wider lens
2. **Attend** - notice, appreciate, and evolve self, others, and process
3. **Reality**- see and be accepting of reality as it is
4. **Vision** -shape a visual story of what can be
5. **Intention** - commit to act, experiment, and create
6. **Resolution** - design-test-learn to realize the results that resolve creative tension

W. DOMAIN KNOWLEDGE
Constructs for your mission and operation
1. **Learning** - integrated practices of learning
2. **Technology** - elements creating product/service
3. **The Ropes**- rules of decisions and cadence of operations
4. **Models** - how organizations create value as a system
5. **Constituencies** - collaborators, stakeholders, and customers
6. **Culture** - norms, values, and power of the organizations

X. EXCHANGE SKILLS
Skills to fit diverse people and organizations
1. **One : One** - between individuals
2. **Groups** - among individuals
3. **Cross-boundaries** - cross-boundaries, time, and scale
4. **Humans among us** - differences in people, power, and culture
5. **Collective** - co-leaders, co-learners, co-influencers

Y. CHALLENGE SKILLS
Skills fit to patterns of challenge
1. **Perform** - incremental continuous improvement
2. **Discover** - ideation, innovation & creativity
3. **Change** - scaling and transitioning
4. **Complex** - cross-boundaries, time, and scale
5. **Crisis** - high importance and urgency

Figure 7. The Prometheus Leadership Commons 2.1 Framework

Our Knowledge and Skills

The orange tones are the adaptive capabilities that make up our knowledge and skills. The darker red tones are domain knowledge, the intellectual stuff. The orange tones are the contexts in which selected skills can be prepared and learned. We expect these to be well mastered in applied experience and integrated across related knowledge domains, self-integrated emotionally and socially. However, they may not only be the theoretical and technical knowledge we assume.

These are all handy for assessing, working and interacting in the real world. We can sometimes do this well in with humility, good purpose, intellect and observation and with little knowledge and few honed practices. This is the truth behind the idea that building the leader, the inner work, is the most adaptable. Or “Who you are is how you lead.” But our situations are often not that simple. We may not be in a safe-to-fail context. We may not have perfect or even viable constituencies. The reality we face may be more chaotic and complex than we can assess on the surface. We have some natural talents but other capabilities for influence and transformation may take some work. To illustrate, while improvisation can be natural, even improvisation is improved with conscious rehearsal of the practice.[9] We may be better at it in our own minds than is objectively true.

We humans (at least this one) tend to over-prepare. We do not (yet) trust our native ability and accept our flaws. So, we over-invest in collecting up knowledge. We do not dare the shame to be imperfect in public, so we are scripted and rehearsed. This is, obviously, not what we are suggesting by highlighting and valuing knowledge and skills.

---

[9] We consider practices to be technique and mindset honed in experience.

I will lastly point to the irony of some who claim knowledge and skills and practices are less important – but assert a set of knowledge and practices for developing leaders or shifting cultures. Those same may assert that their leadership in the industry is built from their research and technologies. What would Loretta Castorini, Cher's character, say?

Leading is Action

The third meta-domain in green tones is the Action of Leading domain. Whatever the details of your situation, these six things are present (or should be) to lead and succeed.

The darker green sub-areas (three to six) are somewhat of an iterative sequence of plan-do-check-repeat. You could consider them standards of health for creative change, so if we understand them we have language to raise concerns. Can we have a suitable strategy if we do not have a sense of where we are and where we want to go? In some cases, we do not have either of those clear, yet we are working hard. The lighter green sub-areas (one and two) are context for the others. Framing gives a context to action. Attending is considering and sustaining people and process.[10]

Some of these areas in the Action of Leading will fall in place, quickly and effortlessly. Some of them will be a lot of work to influence and align, with many teachable moments that require patience and experimentation. Vision, for example, is sometimes clear and quickly finds a resonance with the stakeholders and effortlessly fits the larger context of the mission. In other times, this is a major effort that takes much knowledge, learning iterations, a toolbox of techniques, human connections and open minds and hearts.

Finally, the sub-area labeled Resolution is referring to resolving the creative tension that is energized by the contrast between accepting Reality as it is and a vibrant compelling Vision. This may be one of the most valuable points to remember – because many of us practitioners and researchers forget that leading is not about just being there, thinking or doing, or inspiring. Leading is ultimately about results – whatever those results may be. **We lead** because we want change. **We lead** because we want to learn. **We lead** because we want to create. **We lead** to create what we want and what we want the world to be.

Conclusion

That concludes a summary overview of leaders and leading in the view of the framework and as it stands at this point of publication. While we very much welcome and expect disruptive contributors and amplifiers, we prefer some 'yes, and' partners. We very much look forward to applying and learning to bring this framework to more usefulness and fulfill The Prometheus Project's humble-audacious mission of making leading clear and leaders common.

Thank you for your attention, your shared passion and commitment to leaders and leading, your shared sense of urgency for the broader possibilities we can create in the world.

---

[10] If you are an experienced Agile practitioner, you will recognize that an intentional effort to open and sustain individuals and relationships, observe what works and take responsibility for improving the effectiveness and efficiency of a system of action is 'attending.'

Psychosynthesis and the Alexander Technique

Marilyn Monk[1]

Introduction

After many decades as a practising scientist in the realm of molecular biology (DNA replication and repair, cell signalling, gene expression in development, epigenetics, embryonic stem cells, diagnosis of genetic disease and cancer), I felt a need to expand my occupations in life into the realms of art and spirituality. Although since childhood I was aware of the three realms of knowing and being as mind (objective truth), body (subjective truth) and soul (transcendental truth), I was aware that my science was taking up a disproportionate amount of my time. So, after many years of sampling the various approaches to self-exploration offered by the personal growth movement, I chose to train in the Alexander Technique. I had done the rounds of individual and group work, seminars and the different alternative and complementary therapies and treatments available. But for me, Alexander technique seemed to be the answer because it enabled me to *take responsibility to work on myself* each moment of my waking day and in every activity, whether mental, emotional or physical. Today, I still have great faith in the technique and see it as a valid approach to self-mastery. Yet something still seemed to be lacking. During my own training in the technique and while working with my pupils, I found that release of tension in the body would sometimes be accompanied by overwhelming emotional upheavals. At such times, fellow trainees would simply notice with understanding and compassion and continue with their own work. As a teacher, I have learned to be with pupils during periods of emotional release, to wait quietly and sympathetically, and then proceed, perhaps more slowly, with the teaching. The philosophy is that as the physical back becomes stronger it is able to support more opening of the body over the regions of chest, heart and stomach and, in my experience, this is what happens. Opening the front of the body is equated to opening to vulnerability. It is also quite a courageous confronting of the world outside ourselves.

I believe that psychological and emotional disturbances are slowly resolved during Alexander training. Nevertheless, I have always felt the process to be incomplete, in that we do not directly deal with the roots of our basic emotions – grief, terror, rage, shame and despair. In our training, we are taught that we may have emotions, but our primary concern is about the choice as to whether or not we let these emotions pass into the body. Many people criticise Alexander teachers for their apparent lack of visible emotion and associated body movement (hence the label, 'Alexandroid'). However, these critics may be lacking in perception and awareness. They may not be able to see that the greatest depth of passion and emotion can be felt and portrayed in

---

[1] **Marilyn Monk** is UCL Emeritus Professor of Molecular Embryology at GOS Institute of Child Health, London. Her research has covered mechanisms of DNA replication and repair, bacterial viruses and plasmids, amoeboid cell signaling and aggregation, development of single cell molecular biology, DNA methylation and epigenetics, regulation of gene activity in development, mechanism of Lamarckian inheritance and, clinically, preimplantation diagnosis of genetic disease, deprogramming to embryonic stem cells, and embryonic genes re-expressed in cancers.

stillness. The Alexander teacher is taught to trust that emotional upheavals resulting from release in the body will resolve in their own good time. Alexander technique is certainly not in a hurry. My own inclination, perhaps born out of so many years of scientific discipline, is one of leaving no stone unturned. I am impatient and unwilling to wait for the answers to come so slowly. I felt the need to look more intensely into my own emotional status and its history. Hence, after completing the Alexander Technique training, I decided to train in Assagioli's Psychosynthesis. Each training takes place over three years.

I have been aware throughout the Psychosynthesis training that it is wonderfully complementary to the Alexander Technique. I hope I can convey a flavour of this in this brief article. The Alexander training is concerned with psychophysical awareness and conscious constructive control in the use of the self. Although, Assagioli's Psychosynthesis claims to be concerned with the body as well as with the emotions and transpersonal dimensions (a term often used when avoiding the word 'spiritual'), its attention to the body falls far short of that provided by Alexander Technique. On the other hand, it directly addresses the aspects which Alexander Technique leaves students to resolve by themselves – the psychic and emotional disturbances. I consider that these two disciplines together provide a complete and integrated approach to self-realisation.

Life is Essentially 'Good'

For there is nothing either good or bad, but thinking makes it so. Shakespeare.

One of the basic tenets of Assagioli's work is that life is essentially good. This is perhaps a difficult concept for a Judeo–Christian community indoctrinated with the duality of heaven and hell, good and evil, right-doing and wrong-doing. Yet alongside our Judeo-Christian dogmas runs a stream of myths and fairytales, familiar since childhood, which hint that this duality may not be the only truth. Certain myths and fairytales portray apparent evil as simply the absence of goodness. It is the familiar question as to whether darkness exists of its own accord, or whether darkness is simply the absence of light.

While watching Disney's version of Hans Christian Andersen's *Sleeping Beauty*, it seemed to me that it was all very well for Princess Aurora – young, beautiful, loved and cared for by all. She would have no problem at all in expressing, or reflecting, pure love. But my heart went out to the 'evil' fairy, Carabosse; shunned and rejected, uninvited to the party. Self–destructive, resentful, seething with hatred and seeking revenge – all clearly brought about by the absence of love. Recently, too, on the underground in London, I noticed a poster advertising the ballet. Again, I was struck by the cruelty (and the ageism) with which Carabosse is portrayed – old, arthritic, wrinkled and sallow. No doubt she would also be toothless if she were allowed to smile. But there are no smiles for Carabosse.

Is evil the absence of love? So, I must look further into my experience into the question of the duality of good and evil. The resolution comes not from my thinking on this question, but by way of direct experience of the workings of the Alexander Technique. The experience, simply stated, is that *when I eliminate the wrong–doing, the right comes through of its own accord.* You will notice that I say the 'right', and not the 'right-doing', because the 'right' may not necessarily be a 'doing' at all. As we proceed through this article, we might find a better term term for 'right' – maybe 'harmony', 'poise' or 'balance' – but for the moment, I wish only to make the point that the experience is something that seemingly comes as a gift, or a state of grace, and not something we can do or attain by a certain set of activities of the body. Eliminating the wrong-doing is more akin to 'un-doing' or 'getting out of one's own way', as we shall see below.

Are there other arguments that life is essentially good? I often look to the creatures of existence for answers. Certainly, I consider that the concept of evil is human; it is a human thought construct. The trees, the birds, the foxes and squirrels in my garden do not operate in a world in which evil, – in terms of a force which means them harm, – plays a part. They may sometimes suffer from cold or hunger or 'designs' on each other (the threatening call of the tawny owl and the squeaks of his captured prey are common night occurrences) but, to my eyes, the 'default' state is one of celebration. That is, like Newton's second law of thermodynamics, the creatures of existence will rest or play (visibly enjoy their aliveness) unless propelled by some external force to do otherwise. In my own case, not feeling particularly enamoured with the status of human being (in fact, I feel rather the reverse), it is a simple step, born of observation, to see that there is no evil but that "human thinking makes it so." One memory from the teachings of a spiritual master, Shree Rajneesh, which is indelible upon my being, is his saying, "Existence is not against you. Existence has given birth to you. She loves you." This means to me that to grow, to flourish, and to be in harmony with all – this potential is my very birthright.

We come into the world with all that is required for harmony and balance in the life ahead of us. Small children, when they first begin their physical activity in play, are beautifully balanced. The disproportionately heavy weight of the skull of a two-year old is delicately poised on a perfectly balanced spine in a body that hinges like a little anglepoise lamp in all the right places. What happens to distort this balance – even by the time we are six years old? Alexander maintained that ‘wrong-doings’ multiplied thousands of times become indelibly imprinted, or 'wired in', upon the developing being, resulting in distorted patterns of responses to the constant stream of stimuli in life. Distortions result from physical, mental and emotional ‘wrong-doings’ in response to a world that seems to be against freedom, against authentic true being. The conveyers of the 'right-doing' (parents, priests, teachers, politicians) believe that their impositions are for the best. They are oblivious to the possibility that 'imposed doing' of any sort may be stunting the child's natural growth. Very few people in our society consider that the task of the mentor is primarily to enable the new being to flourish in its own unique way.

Although distortions inevitably accumulate, the birthright for fulfilment of potential, though latent, miraculously survives. This is the positive, good news part of the story. And it is where F. M. Alexander and R. Assagioli had much in common. Both believed that goodness and right-being were the essence of human existence, and that a latent sense of a harmonious self could be revealed by stripping away the psychophysical and emotional distortions built up since birth. Alexander's tenet was that in all walks of life, in all human activity (mental, physical, emotional), there is a misguided emphasis on trying to get things right and too little attention paid to what has gone wrong in the first place. He maintained that 'getting things right' places an undue emphasis on gaining an end, rather than on paying proper attention to the 'means whereby' the response to a stimulus is activated and performed. This state of 'doing too much' and end-gaining inevitably overlayers natural functioning with super–imposed tensions to the system which in turn distort the natural balance of the psychophysical being. Even trying to see, or trying to think, can interfere with the efficient functioning of eyes and mind (memory). In a similar way, Assagioli asserted that individual human beings carry within them unspoilt qualities of peace, harmony, joy, radiance and wisdom; and that these pure qualities become layered with distortions built up by early trauma and continual disturbances throughout life. The approach of both men is to bring the distortions into the light of consciousness and, at the same time, to make clear the potential of the latent pure qualities needing to emerge once again. Their methods are different but their intentions to encourage the emergence of the inherent best being in each of us are the same.

Taking Responsibility

God helps those who help themselves. Mum and others

Nowadays, we look to the medical profession as a service. It is there to provide a 'quick fix' to our ailments – those things that go wrong in the body. The same approach is taken by many towards the complementary health therapies. We tend to go to the doctor or therapist with our depression, fatigue, headache, stomach pain, respiratory disease, skin disorders and many other symptoms of stress (tension), and ask for help to alleviate our suffering. The doctor may prescribe pills, ointments, medicines and treatments of one sort or another. But how would we feel if the doctor said, "Well now, how have you done this to yourself?" Yet, in many cases, this approach would be the most true and the most helpful for, more often than not, we do not take the time to consider our own relationship to the age–old basic rules for good health: – appropriate diet, exercise, rest, sleep and avoiding stress. Nor are we educated to take responsibility for our own health and well-being. Modern medicine is about illness, not health. It is interested in disease and takes the responsibility (and fattens the drug companies) for prescribing 'fixes' for ailments that are primarily caused by our own lack of care for ourselves. Today's human beings are not remarkable for taking responsibility. That is why the story of F. M Alexander's struggle to find the solution to his own particular ailment is so inspiring for us all.

Frederick Matthias Alexander was born into a large rural family in Tasmania, Australia, in 1869. He was a separate, and perhaps somewhat difficult, child with a passion for acting and reciting on stage. In his late teens, however, his passion to act and to recite was severely compromised by a tendency to lose his voice. He visited many doctors and specialists of throat disorders, but nobody could find an anatomical or physiological defect to explain his loss of voice. He was advised to rest, and in so doing, his voice would return; but as soon as he would recite again, his voice would become hoarse and weak. Alexander made a simple observation that many of us would be unable to make (although we may not like to admit it). He saw that *it must be something that he was doing when engaging in this activity that was causing his problem*. This initial step of taking responsibility for his problem was the starting point of a determined, thorough and painstaking scientific investigation by Alexander of his own use of himself'.

'Use of the self' is an Alexandrian term that may need qualifying. The best approach to understanding use of the self is to consider the way we use various tools in life. We pay attention to the shape and feel of a pen, a saw, a toothbrush, a golf club, and so on, and consider whether the tool will function well in the task intended. After purchasing a food processor, a new car, or a video recorder, we will read the instruction manual and give some time and thought to the proper use of the new equipment. We pay attention to proper use since we are aware of the simple universal law, 'Use affects function.' Its colloquial addendum, 'Use it or lose it', is also important. Examples of this, well-known in biology, are vestigial organs (tonsils, appendices, ear muscles), lack of development of blocked or 'blinded' organs in new–born animals, atrophy of unused leg muscles, and so on. Proper use of ourselves is vitally important for maintenance and appropriate function. But do we pay any attention to the way we use ourselves in daily activity? The means whereby we use ourselves – whether distorted, tense and unbalanced, or poised, flowing and free – will profoundly affect the possibility of continued function as well as efficiency of function and, just as importantly, pleasure in activity. Poor use of the self is a constant force for deterioration in muscles and joints, and in mental and emotional well-being. Good use of the self is progressively enhancing to overall health and well-being. Evidence for the effectiveness of Alexander training on health-enhancement is rife – for example, increased lung capacity, lowered blood pressure, less expenditure of effort in activity and more balanced emotional and intellectual presence.

Alexander observed that in response to the self-given stimulus to recite, his pattern of response in taking up a 'reciting stance' was to pull the heavy weight of his skull back and down on the top of his spine. This resulted in a shortening and narrowing of the back and a gripping with the feet that distorted overall balance. The second stage of Alexander's enquiry was to try to change this pattern of response. The frustration of trying to break a habit of this sort would be enough to deter most of us, but Alexander's determination was quite remarkable. He first tried imposing the "doing" of something different – *trying to* ***do*** *it right*. However, thrusting the head forward caused more problems – more tightening of the throat and restriction of breathing and of the diaphragm. He then realised that he must simply eliminate the wrong pattern and not try to superimpose what he thought might be the right pattern. The third stage of his investigation might be considered as a still more difficult hurdle. He had to *break his conditioned response pattern to the stimulus* to recite. After many months of perseverance, Alexander had finally developed his method. Stated simply, he had learned to put a pause between stimulus and response and, in that pause, to give himself mental orders both to release any unnecessary tension and to encourage new direction. He mentally ordered his neck to be free to *allow* his head to go forward and up in relation to the top of his spine (thus freeing the joint between head and spine). As a result of these mental orders, he would experience his back lengthening and widening as if of its own accord (in response to his having 'got out of the way'). This experience is due to the natural postural reflex (through the spine) mechanisms now able to come into play. The job of the natural postural reflex mechanism is to govern a lengthening process in the body in response to gravity – the very experience of lightness of being that is so often reported by the Alexander pupil.

The pause, or hiatus, inserted between stimulus and response and the releasing of inappropriate tension is called *inhibition*; the new mental orders are called *direction*; and the proper relationship between head, neck and spine, undergoing delicate readjustments moment by moment, is called *primary control.* Thus Alexander had solved his problem and, moreover, he found that the same principles could be applied to solve or eliminate any problem in human functioning where the individual concerned was willing to seek out the wrong-doing in activity and to apply new conscious control over his use of himself. We will now look at the principles of Alexander technique in relation to the main principles of Psychosynthesis in order to observe the ways in which they are parallel and complementary.

Inhibition and Dis-identification

Give thy thoughts no tongue, nor any unproportion'd thought his act. Shakespeare.

A common hypothesis to both Alexander Technique and Psychosynthesis is the existence of a unique *self*, with pure qualities of love and will, needing to emerge from underneath the covering layers of accumulated distortions. Distortions, according to Alexander Technique, are the habitual patterns of faulty psychophysical use in response to stimuli; in Psychosynthesis, they are inappropriate, exaggerated or damaging behavioural responses. It is also common to both disciplines that the *self* needing to emerge is always present, so, in a sense, the emergence is one of re-membering. In fact, Alexander technique is classified as *re-education* of the individual in proper use of the *self*. It is also common to both that the process of stripping away the layers of accumulated distortions requires 'conscious constructive control' (Alexander's term). By this, we mean that the work is done initially through a properly trained mind aided by the engagement of conscious will, or intention.

Another term used by Alexander is 'inhibition'. There are many ways to see the concept of inhibition. Perhaps the simplest representation is that of saying 'no' to immediate (and therefore habitual) response to a stimulus: The telephone rings; there is a shove in a crowded place; there is a move to sit, stand, write or play a musical instrument, switch on the TV or hit a tennis ball (the reader will get the idea of any and every daily activity). The response must be to say 'no' to responding at all. This is in part 'inhibition' – it is the first step towards breaking the habitual wrong response pattern. Even when I think I am doing nothing, I must practise inhibition because, in fact, there is never a time when I am not responding to a stimulus. It may be a thought or an emotion and, if I remember, I can say 'no' to that thought or emotion entering my body to change it in some way. For example, if I feel 'down', then I say 'no' to the response of pulling down in the body. So 'inhibition' is simply staying very aware of the constant stream of stimuli that come into the mind – stimuli wanting a mental, emotional or physical response – and saying 'no' to responding to a stimulus in any way other than noting it. (I, myself, assume that all emotional and physical responses also start with a thought).

Of course, this is a very tall order, and often I am not aware that I am carrying thoughts, feelings and muscular tensions that are a pattern of response to a *previous* stimulus until a clear new stimulus attracts my attention. Then the task of 'inhibition' is to release all aspects of the old pattern, as well as saying 'no' to responding immediately to the new stimulus. The practice of 'inhibition' means that I do not carry over a psychophysical pattern belonging to a previous event into my response to the new event. I clear the system. Before responding to the new event, I also must practise the next Alexander principle: 'direction.' The practice of inhibition and direction means that my response will be from a more balanced and clear space and therefore it is more likely to be an appropriate response. It will also mean that my neck will be free to *allow* my head to go forward and up in relation to the top of my spine, which will be lengthening back and up. Another way of seeing inhibition in more physical terms is that I will stay back (the physical back stays back) from the stimulus. I will not be pulled into it. This will all become clearer when I say more about direction and choice, below.

In the practice of Psychosynthesis, one of the key principles is *self* identification – a conscious and disciplined process of dis-identification from the mind, the emotions and the physical body. In my own experience, practising dis-identification is very similar to the concept of inhibition. In affirming that I am more than my thoughts, emotions and physical sensations, I am visualising myself as so much bigger than the content of these faculties that the content itself diminishes in significance. Indeed, combined with meditation (releasing tension, staying alert, watching, non-censoring and letting go of desire for a particular outcome), the practice of dis-identification can approach the same state of still and silent readiness that comes about in the practice of inhibition and direction in Alexander Technique. This is the state we yearn for, i.e., 'nothing happening but anything possible', – and that is so beautiful to see in the total 'being-ness' of a young child.

Direction, the Will and Choice

This above all – to thine own self be true. Shakespeare.

In a small child, the natural orientation of the head to the neck and back is such that the joint between the heavy skull and the delicate top vertebra of the spine is free (the jaw is also jointed here and the position of this joint is between the ears). Over 90 per cent of stimuli are received in the head (sight, smell, taste, sound, thought) and, if the head is delicately balanced and free to respond, the lengthening back follows this response in a flowing and free way. Alexander found that it was necessary to give a powerful positive mental order to will this natural orientation to come back into play. Combining 'inhibition' and 'direction', we sa*y, "Let the neck be free to allow the head to go forward and up in such a way that the back lengthens and widens."* Note that the instructions do not imply that the pupil will **do** anything. The pupil is instructed simply to give mental direction and *trust* that the thought will be understood and translated by the body into an appropriate response. The teacher's presence and gentle guidance with the hands will confirm this. Inhibition and direction practised in this way ensure the best possible poised and balanced place from which to make a response. It is clear that a free and balanced psychophysical self is more likely to respond appropriately to any stimulus. Alexander maintained that a contorted, distorted body would result in distorted mental, emotional and physical perceptions of the events occurring in the outside world.

Now, and only now, the individual is ready to respond and now there is choice. Simply put,– the individual may choose not to respond at all; to respond in a completely different manner than usual; to do something completely irrelevant (a useful choice with adolescent kids); or, of course, to respond in the old habitual way (although in the latter case, now there is something very different – a *choice* to do this has been made).

Alexander technique is therefore a form of self-mastery in that its practice allows me to have a choice from a free and balanced place of how to respond moment by moment to the constant stream of happenings in my world. It also *allows the **possibility** of change*. Not that it is *about* change; but, in unlinking habitual response from stimulus, it opens the possibility of responding differently. Ingrained habit is the most difficult barrier to change.

Now, how is this aspect of direction and choice seen in Assagioli's Psychosynthesis? Clearly it is in Assagioli's concept of the 'Will' in all its forms. Primarily, the Will is an intention (mental image) that translates itself into physical embodiment and action. The Will in Psychosynthesis has a directive and regulatory function, balancing and integrating the energies of the being. Alexander's own words, "conscious constructive control,", could as equally apply to the Will of Assagioli as it does to primary control. The main aspects of the Will as strong (intensity of energy for action), skilful (effective strategy with least effort) and good (appropriate expansion into the outside world) emanate from the *self*. Right use of Will is associated with a sense of harmony and choice, akin to Alexander's direction and primary control. The Will directs with energy, mastery and purpose; but it is *effortless*.

Grounding and Self-realisation

Individuation only takes place if you first return to your body, to your earth, only then does it become true. Jung.

It is perhaps paradoxical that the aspect of grounding in Alexander Technique is strongly related to the sense of a higher self. The Alexander teacher uses gentle guidance with the hands together with quite insistent and intense verbal instruction (remember, thoughts have to be trained and the Alexander teacher must be holding, and even staying ahead of, the pupil's habitual thought patterns). With the engagement of the pupil's will, the teacher helps to bring about a new state of poise and balance in the pupil. Then the pupil will often say that they are suddenly aware of the fact that they have feet. They feel their feet on the ground solidly supporting them. They are grounded. Although they are free and flexible, the teacher will be aware that they are very strong and together (I found that the same supple, grounded strength is developed in Tai Chai). At the same time as being grounded, the pupil is aware of being in alignment with a lengthening process streaming up through the body and a sense of lightness, expansion and well–being. Every part of the bodymind is now in communication with every other part. This 'suspension structure', grounded by gravity, is also very sensitive to the world around and communicating openly and freely with this world. Pupils will often say that they feel that they are simply who they are; that they see clearly; and that this experience is very welcome. On the way to this place of togetherness and poise, the student has had to pass through many unfamiliar places, often feeling very off-balance indeed. Remember that what feels familiar feels right and whatever the pupil's habitual distorted patterns of holding, these will seem right, even if the tension is very disabling. Thus, the process requires some courage. The pupil must be willing to enter the unknown.

A similar passage may happen during the course of Psychosynthesis counselling. During a phase of intense work, the client may feel quite lost and on very unfamiliar ground. The Psychosynthesis guide will hold the true identity of the client through these lost periods and provide support and encouragement to the client to continue the exploration of who he or she really is. The realisation of a new insight or truth closer to the real self comes with grounding of these new experiences into daily life: – practising re-calling the new clarity of vision; noticing how harmoniously it fits with life; taking on new aspects of self-identity in a stable and actualised way. Thus, in Psychosynthesis too, grounding is associated with a greater sense of *self*. It opens new doors and expands the sense of being by integrating more and more acknowledged aspects of *self*, thus strengthening self-identity and lightening the burdens of daily life.

The Meaning of Change

We shall not cease from exploration
And the end of all our exploring
Will be to arrive where we started
And know the place for the first time. *T S Eliot.*

Of all complementary health therapies and treatments available, Alexander echnique and Psychosynthesis are special in that they ask the adherent to take the opportunity to *work on themselves* in daily activity. They are not treatments administered to a passive recipient. In addition to working together, teacher and pupil also work on themselves alone. In fact, the process of giving an Alexander lesson is that of the teacher working on themselves and transmitting their own good use and strong direction (intention, Will) through non–interfering hands to the pupil. Both disciplines ask that the pupil or client be responsible for his or her own well–being and unique flowering into the best possible being that they can be, free from the imprisoning constraints of accumulated distortions superimposed on the finer qualities of his or her self expression.

But here I think lies the greatest pitfall – the desire to change. In Psychosynthesis, it is essential to stress that the goal is one of uncovering the essential qualities of the pure *self* that is *unique to that individual*. Unfortunately, this is often interpreted as trying to be a different *self*. In Alexander Technique, the emphasis is on eliminating the wrong-doing, not trying to get it right. But no matter how often this is stressed in lessons, I find that the pupil is still trying to get it right. To my mind, this is the worst affliction – wanting to change – and the danger of these disciplines is that they may *create a desire to be different or better.*

It is a common cry heard from many who have worked on themselves for years: – that they are seeking to become better or different, seeking peace, harmony, clarity, wisdom, radiance and love; but that – this is not happening. Why is it so difficult? How is that we can still be so destructive to our selves when, after so much work, we *know* what is needed and what is not needed moment by moment? Simple wrongs of excess or obsession – staying up late, eating too much of the wrong foods, not getting enough rest, not meditating when we mean to, being tired and irritable – behaving destructively despite our best intentions. What is the nature of this destructive force? Evil? Have I come full circle to disprove my starting premise? I do not think so. Instead, I believe that the destructive aspect is actually *created in response to the desire to be better or different*. Only human beings create this polarity. Does the rose want to be a lilac; does the cat want to be a dog; does the horse yearn to become a unicorn? I like to believe that the rose wants to be the best rose that it can be – a full flowering of colour and fragrance and beauty of its own true form. Life is not normally self-destructive. All desire to be other which brings destruction and frustration belongs to humankind. Desire of any form means frustration. In fact, I see satisfaction as simply the alleviation of frustration, not the gaining of the object of desire.

Our goal then is to drop goals beyond our reach and to live fully in the moment, *fully accepting and loving our unique selves*. We must let go of the wrong-doing of striving to superimpose some projection we have of who we might be. Paradoxically, coming back to who we really are opens a greater potential for who we might be; but this is not a promise. We are simply in with a chance to receive a gift which may shine through when we get out of the way. This will not be something we have tried to achieve, but a gift that was ours from the beginning.

Relations Between Cognitive Development and Spiritual Practice (Yoga)

Huw Lloyd[1]

Abstract: In this essay I relate aspects of cognitive development to spiritual practices such as yoga and highlight the role of active orientation. I describe some personal experiences stemming from certain developments bridging cognition and yoga, whilst also relating these to societal biases that fail to address the potential for developments of this form.

Introduction and Personal Experience

In April 2017 whilst exploring some literature on the periphery of developmental psychology[2] I found myself experiencing some unusual phenomena foreign to conventional psychological accounts. In my subsequent searches through various literature, certain features of these experiences only corresponded to accounts presented in yogic literature. These remarkable, yet personal, experiences were of such uniqueness and distinction that I felt compelled to enquire into this newly emerging personal sphere. The new thread led me to widen the conception of active orientation that I had previously discovered and recognize its coherence with conceptions central to yogic science and apparently all mystical disciplines. At the same time, these newly emerging experiences appeared to be congruent with some of the more speculative frameworks of cognitive development[3] indicating a continuum between conventional cognitive development and that of higher states of awareness.[4]

---

[1] **Huw Lloyd** is an independent researcher in developmental psychology, cybernetics, activity systems, and technical mediation. He has also worked, and consulted, as a programmer for a variety of businesses and domains, with an interest in fostering productive working environments conducive towards personal development
huw@bootstrapsystems.co.uk

[2] This literature conveyed similarities to the processes of morphogenesis in skill formation which I had been studying.

[3] Cognition, in the sense that I refer to it, may be described as "the guiding aspect of activity". It typically pertains to how an activity is to be undertaken, as the process of formulating (and revising) a plan of action that necessitates conscious attention. This simple description recognizes cognition's integral role in activity, with an emphasis upon the directing of attention through the use of signs (of varied kinds). Consequently, cognitive development pertains to the reorganisation of the structures used in cognition, notably the nature of the logic employed. Due to the integral nature of cognition with other mental faculties, transformations in cognition implicate significant and often profound changes in one's relations to the world. Although cognition may be applied to both thought and emotion, I typically emphasise cognition as thought, whilst recognising the close coupling between thought, emotion, movement and intentionality.

[4] Frameworks such as those of Graves (2002) and Jaques, Gibson, & Isaac (1978).

SOME RIGHTS RESERVED

I should like to stress that prior to these experiences, I was largely ignorant of yogic practices and indeed I had not undertaken any overt exercises that might be recognized as formal meditation. This happenstance suggested to me that the mental skills that I had some fluency with (reflective and systemic thinking) might have some correspondence to meditation. Further research led me to a central factor linking the two sources of literature (developmental psychology and yogic practises), this was my personal discovery of active orientation and the processes implicated.

In my original conception of active orientation (Lloyd, 2016) I describe a process in which action, thought, affect, and construal come together (are coordinated) through an interaction of intention, skill, and situational context. Unbeknownst to me, this coordination is highly congruent with mystical principles of achieving coordination and control of different "bodies", called koshas, or aspects of bodies[5] such that, upon successful alignment of them, new vistas become apparent in the form of faculties which were previously obscured.[6] Indeed the formulation of active orientation has some striking parallels with "Ratha Kalpana", an analogy in the Katha Upanishad that compares functions of man with functions of a chariot (Ratha Kalpana, 2021), see also Gurdjieff's description of a coach and horses (Ouspensky, 2001/1949).

The implications of both these findings and the experiences were, for me, profound and initiated a protracted process of reorganizing my understanding of the world. Prior to these experiences I had arrived at a fairly resigned recognition that the higher reaches of cognitive development were largely rejected by society at large including within the sphere of academia. The unusual experiences facilitated a significant transition in my world view.

The unusual experiences may be conveniently grouped into three categories. All of these experiences are of a personal character. Furthermore, these experiences may be described as the initially novel experiences, they are not comprehensive. I am also quite confident that from the perspective of an accomplished yogi, these descriptions are quite banal.

i. The sensation or awareness of energy (prana) within the body.
ii. Awareness of synchronicities.
iii. Unusual dreams of an archetypal or spiritual character.

The first category pertains to an awareness of energy in the body that may manifest as a form of sensation and that is often located in the regions attributed to certain chakras. Usually it is of a sense of energy gently residing or moving in a given location that may be seemingly superimposed upon conventional sensation. An exception to this was an experience that was in agreement with accounts of "kundalini energy" which entailed a dramatic ascent of energy within the body.

The second category agrees with Jung's (1955) characterization. A simple example would be the timely coincidence of three personal events: my discovering new information to an old problem, insight into a method for resolving the problem, and someone unwittingly providing me with an apparatus that I will only be aware of needing when attempting the method that the problem pertains to. In such a synchronous situation, these events might all transpire within a short time frame (within hours, or the same day).

---

[5] Sadhguru (2016) asserts that thought and emotion are considered to both belong to the mental body.
[6] Obscured through the friction and dis-coordination of the bodies.

Of the third category, an example might be a meeting in a dream with an archetypal figure such as a lady resembling Athena. Of the spiritual variant, I might dream of a happenstance meeting with someone I know of, but not necessarily know personally. Such an occasion occurred whilst I had a chest infection. In the dream I happened to meet someone who was familiar to me from childhood experiences and wished to speak to me. The following day, I sought information about this person and discovered that they had died recently from a lung disease.

On the basis of my experiences and their close correspondence with yogic formulations along with a recognition of the systemic cohesion of the formulations, I found myself to at least be responsive to the broader yogic ideas. These ideas have a very good alignment with my experiences. However, when I have previously sought some contact with Western cultured people who might be aware of such terms like "kundalini" the direction has led to communities dealing with crises. That is, "kundalini" in the West often seems to be associated with crisis in the sense of extreme difficulty. This, however, has not been my experience at all. My experience and thinking has remained lucid, whilst the awareness of synchronicities has remained within a dual perspective in which the synchronous meaning is framed as an "as if". This, I understand, is a quality that persons referred to as psychotic do not enjoy. This experience might also be considered as one data point contributing to the project sketched out by Gopi Krishna for a scientific study of kundalini (Krishna, 1970, ch. 19).

There are, of course, many other details that I could describe and that are of a personal nature. Clearly, these presented experiences are open to criticism and may be reduced to labels of "subjective imagination.” It is not, however, the purpose of this essay to prove the existence of these phenomena. One need not rely upon descriptions of these experiences to appreciate the coherence between studies of psychological development and those of 'mystical' development. Similarly, looking to the kinds of transformations that take place in children, one might not be so surprised to discover the possibility for further, yet similarly structured, transformations in adults.

Rather, my intention is to be candid about the various sources of my understandings and insights into the importance for fostering developmentally[7] fertile environments, to indicate the need for greater cultural openness and awareness of such phenomena and greater opportunities within our society for fostering cognitive development. In the contexts of both cognitive development and yogic practises there seems to be agreement that such transformations do not arise of themselves, rather they arise through sustained conscious effort on the part of the agent.[8]

Prior to these experiences I was immersed, intellectually, in the problem of cognitive development within educational environments. It now seems to me that this pursuit may be appreciated as an expression, within a wider context, of personal and human development. That is, that the focus upon genuine cognitive development within contexts of education is an ethical issue, rather than considering education as merely serving to satisfy our cultural conditions for qualification. This is not, of course, to assert that everyone should be encouraged to pursue a program of cognitive transformation, but rather that, for those who find this practice amenable, it is necessary to acknowledge that it is unethical to harness people to an educational system wholly unsuited to their expressed directions and manners of interest.[9]

---

[7] The principal characteristic of developmental phenomena, as compared with learning and growth, is that of systemic reorganization.

[8] References to a need for consciously directed transformations can be found in Vygotsky (1998) and Davydov (2008). Refinement of consciousness and awareness is also a cornerstone of yogic practice.

Other systemic relations between cognition and mystical practices

Having cautiously explored the phenomena and studied more widely, I can also account for further systemic relations between yoga (or mystic practices more generally) and cognition, which I describe briefly under four categories.

1) Self-observation and Reflexivity

Detached self-observation is a basic practice in meditation used to establish an “inner witness”. In cognitive activity a similar practice is that of reflexivity – of practising reflection upon what one is doing in the act of doing it. Reflexive activity has the additional complexity of balancing activity and reflection simultaneously. Another basic activity, encouraged in Gurdjieff-based practices, is that of practising self-observation to become conscious of the mechanical nature of much behaviour. Indeed, reflexive activity is in principle non-mechanical due to the alert and responsive nature of reflexivity (which entails both reflection and action).

2) Self-remembering and Orienting to Broader Scales of Awareness

Unlike self-observation, “self-remembering” in mystical practices may pertain to recalling to mind the presence of one's greater self (Atman) or the “unchanging consciousness” implicated in “being aware of being aware.” Punctuation in activity, marked by a change in orientation (cessation of outward focus) provides the opportunity for a recurrence of self-remembering or quiescence of mental work. In contexts emphasizing cognitive development, we may work mentally under the appreciation that there are respectively broader and more powerful ways to think about problem contexts. These circumstances can lead to a circumstance in which one “makes room” for the potential of greater intelligence (insights and syntheses of thought) in one's activity. Although in these two contexts (meditation and problem-solving activity) the direction of attention may appear to be opposite it may not be as polar as it may seem, for genuine insights into problems can arise from a mental state of abeyance from mental work once the problem itself has become familiar.

---

[9] Conventional schooling does not support such transformations. It is oriented towards acquiring formal schemas, rather than learning to construe, interpret, and understand. In order to transform one's mode of cognition one must work beyond one's familiar capabilities, engaging in activities for which one does not have pre-established methods.

3) Concentration and “Will Power”

Discipline, hard work and persistence regularly feature in accounts of mystical practice, and the same can be said for intellectual work. Both practices entail self-transformation. Without efforts to “work upon oneself”, significant transformations are not expected. In this regard, the concentration of intellectual work exhibits rigorous mental work akin to the quiescence achieved in meditation, for in disciplined intellectual work the contents of thought are far from arbitrary – only particular and appropriate kinds of thought are admitted to the process. Hence there is a commonality of discipline in the controlled movement of thought with a disciplined inattention to irrelevant factors compared with either the abeyance of thought or single-pointed focus of attention in meditation.

4) Access to “Essence” or Divine Self and Cognitive Development

Mystical practices distinguish between an unreflective and mechanical manner of being that is often associated with a myopic or obsessive focus upon material, bodily desires and those practices pertaining to awareness of the greater Self. Hence in mysticism there is a distinction between the superficial habitual manifestation of being and the being latent with the greater Self. In cognitive work the emphasis of distinction can be placed between the habitual, unreflective activity and the activity that entails transformation in the way one thinks and acts. This cognitive transformational process can be likened to the process by which the mystic approaches the Self. Although in mystical practices the Self is considered to be unchanging, our means of approaching that unchanging nature seems to require much effort and personal transformation.

Complementarity Between Yoga and Cognition

A Russian mathematics teacher who spent many years teaching within a school programme designed on the basis of developmental psychology described his interest as "working with people with wings" (Matusov, 2017, p. 54). This applied to students who exercised the self-conscious direction to learn through active discovery and who endeavoured to resolve educational problem tasks. In the scientific and technical context within which this rationale was expressed, I think that it is relevant that these particular descriptive words were assiduously adopted - “to have wings”. This mode of education cannot, however, be transplanted to school practices that we typically find. It requires a curriculum designed upon an entirely different basis of education using principles of understanding rather than formal knowledge. It entails relating emotion, thinking, and action together in acts of construal rather than of simply learning a prescribed grammar of notation divorced from the intimate experience of problem-solving activity.

It is perhaps also appropriate to address, briefly, a converse shortcoming often found in the perspectives presented in mystical settings regarding the disparagement of "logical thinking" as a reputed obstacle towards higher forms of awareness.[10] These disparagements generally assert that "logical thinking is all about cutting" (or abstracting). It is apparent that these assertions correspond loosely with the category of thought called formal logic. Formal logic, however, is by no means synonymous with logical thought. Thought may be expressed in a variety of logics, of which formal logic is one category that is perhaps the most frequently employed. The thought of "genetic logic", dialectics, or simply of considering the relationship between phenomena is, rather, a movement towards synthesis, of yielding a concrete understanding rather than an abstract categorization that is "cut."

---

[10] For example, Sadhguru (2016) disparages "logical thinking" frequently in the section titled “Mind.”

From what I can discern, the disparagement of "logical thinking" in mystical circumstances may pertain more to the temperament and culture of the practitioners rather than anything necessarily inherent to the realization of 'higher' states of being. Indeed, a contemporary popular yogi gives allowance for the viability of this argument in the recognition of a "yoga of the intellect", Gnana yoga,[11] and, also, an alternative approach to schooling which entails non-dogmatic exploration of a curriculum (Isha Home School, 2021). My own experiences and unwitting "path" certainly seem to have some correspondence with these appreciations which find agreement with the spiritual interests that have been shared amongst many leading practitioners of the systems scientists, who might be considered to represent the acme of Western “logical thinking” (Pickering, 2008).

In a similar context, the consideration by Wilber (2016) that both spiritual development and cognitive development may express different strands of personal development lends some theoretical rationale to the notion that one can exhibit a high level of development in spiritual aspects whilst manifesting quite localized and simplistic forms of cognitive expression. This implies that spiritual awareness is expressed in a manner appropriate to the medium of awareness, thereby paralleling studies of conventional activity and understanding in which understanding is mediated by cognition (Zinchenko, 1979; Piaget, 1980).

Transmodernity: Enrique Dussel at Research Across Boundaries

Editor's Note

In 2010, a rare event occurred, a gathering of researchers from several diverse domains brought together by their passion for integrative, transdisciplinary approaches to research.

> The international symposium "Research across Boundaries – Advances in Theory-building" was held at the University of Luxembourg in June of 2010. It brought together, for the first time, many leading boundary spanning and meta-level researchers from more than 15 countries across all continents and as many different research areas. In what became a set of truly global dialogues, the participants presented and commented an astounding array of contemporary integrative frameworks, as well as inter- and transdisciplinary reviews and research practices across various fields of inquiry of high relevance for the future. (Molz and Edwards, 2013, p. 3)

While a large portion of the works presented have been published previously, (https://integral-review.org/backissue/vol-9-no-2-jun-2013/), a few items have sat unpublished for a variety of reasons. In particular, the present transcript was never submitted in written form. However, the video recording of this session has sat in the background of my hard drive for 10 years.

I recall that session quite vividly. The topic was transmodernity. The setup of each breakout session was to have three presenters, each presenting one of the others' works, followed by dialogue among participants and clarifications or elaborations by the author. However, due to circumstances, Enrique Dussel was unable to participate in this manner and was only able to arrive part way into the session. The first two presenters presented each other's works and there was commentary and general discussion of these going on when Dussel arrived. As he listened to the conversation, I remember him leaning over and whispering in my ear that these people did not know what they were talking about.

Dussel then took his turn and presented his work on transmodernity. In my view, and I believe that of many of those present in the room, he was able to enlighten all of us that indeed, we did not know what transmodernity meant. His passionate and engaging presentation, followed by some questions and commentary, stood out for me during this conference as a window into a truly transdisciplinary and transcultural view.

After repeated unsuccessful attempts to contact Dussel and get a copy of the paper he mentioned at one point, or clarification on segments of the video that were too difficult to decipher, I have decided to publish this as is. You will need to bear with several gaps in the text, but I hope that the main thrust of the presentation comes through. You can find some items, mostly in Spanish at https://enriquedussel.com/index.html.

SOME RIGHTS RESERVED

Enrique Dussel

I would like to come to our discussion. I will improve and say something from the material that we begin to share. I would like to speak of three words. The words are important in our conversation. *Modernity, postmodernity,* and *transmodernity*. I will try to clarify, not to say that this is the content of this conference. But my vision of the three words is to put more material to the discourse.

Modernity

First, modernity. On this question there is a big discussion, and you know better than I. I would like to put my distinction in two questions. When begins the modernity? That is the problem of the old vision. For example you said (*pointing to somebody to his left*) that modernity is the "Ausgang," is the liberation of the stupidity that means the coup de tat, the immaturity. That is the definition of that. That means that you think that the modernity begins at the end of 18th century, for example. And Wallerstein thought that the modernity begins with enlightenment at the end of the 18th century. But we discussed this with Wallerstein and we convinced him that it didn't begin in the 18th century. It began before the modernity. The question of origin is a question of content.

For me, and I can say among a group of thinkers in the United States and Latin America, we agree that modernity begins when Europe woke up of the war that the Islamic world took to Europe. Seventh century. That means the seventh century and the fifteenth century in Europe was various small geographic organisms, very small. Europe was from Vienna until Granada …. One million kilometer square. Sixty million persons. But the big world, and the universal world was the Islamic world. In…, Egypt, Middle orient, Afghanistan, India and Indochina, until we meet now in the Pacific. That means that Europe was a provincial, secondary, never center of history and the only universal world was the Islamic one until 1492. That is very important when talking about modernity, because the modernity comes from their world.

Ibn Rushd, the big great philosopher from Cordoba was the creator of the 17th century philosophical renewal. And modernity comes from the south. That is a clear hypothesis that we can use. For us, modernity is when Europe broke out of this world, of the Islamic world.

The modernity began when Europe went out to Africa, through Portugal, to India, Japan with the Portuguese empire and to America with the Spanish expansion. That is the beginning of modernity. That means 1492. In the 15th century begins the modernity. That is a discussion. For me, it is clear. That is against Habermas, against Toynbee. That is a discussion.

If modernity begins in the expansion of Europe, we have four phenomena simultaneously. That means, we have first modernity as a companion? but that is the beginning of the world system in the sense of Wallerstein. That is the beginning of the connection between Europe, Africa, Asia, America, the first world system in history because America was not part of any system before. What system? This is the beginning of the colonialism, because never were there colonists in the other part of the continent. The Roman Empire did not have colonies, it was an expansion of the same. Chinese empire was the expansion of the same. But to have colonies in the other part of the ocean is a novelty in modernity. That is colonialism.

Then capitalism. Capitalism begins not only in the experience of the feudal cities but is the accumulation of wealth from the periphery to the center. From America come more than 20,000 tons of silver. And that is the primitive accumulation. And all of that doesn't give a possibility of a very Eurocentricism of value.

That means the centrality of Europe in the world system is not in 1492, not for three centuries. After industrial revolution, that means in the 18th century, Europe becomes hegemonical in this world system. But during three centuries, until the 18th century, China and India were the center of technology, astronomy, mathematics and commerce. That is to discuss. But only Europe took advance to China and India in the end of the 18th century, beginning of the 20th. That is the centrality of the world system, is in the hand of Europe only two centuries ago. That is for me modernity. The culture of Europe that is the hegemony from two hundred years. That is the idea for discussion.

Postmodernity

The second, what is postmodernity. Postmodernity is very recent. In 1979 Lyotard wrote this book on the postmodern condition. But before and in parallel there are many epistemological narratives like, cultural studies, post-colonial studies in the colonial English departments. Subaltern studies beginning in India, and after they became very popular in the United States and many others.

But the last moment now is the coloniality of the epistemology. It is a Latin American group in the United States that said exactly that coloniality begins not like in the Commonwealth in the 18th century but began in the 16th century. That means there, for three centuries before, a colonial world and a modernity. We are against this hypothesis of the postmodern. For us, postmodernity is the last moment of modernity. It is a Eurocentric criticism of the dominant reason of Europe. But it is from the point of view of Europe. Because Lyotard and others, all these thinkers are Europeans. For us, it is not a question. We use the word *transmodernity* in a very precise meaning. That is against postmodernity and is another moment of modernity. It is not one preview of modernity, but it is another epoch. This other, I cannot say how, these 500 years of modernity begin to finish. And this is another age of the planet, or epoch.

But I would like now to make a description. *(Draws on the flip chart).* If the modernity is like a cone of light. That means here is the light and that is the cone of light. And for example, Latin America is here as a culture *(Dussel drawing an intersection into the cone)* plus the process of the inclusion of Latin America as a colony began in 1492. That is the exploitation of richness, the importation of food, many dominational processes in relation with Latin America that began there. But the inclusion for example of Africa is after. Because in 1885 was the congress of Berlin. That means Africa was invited one century for us. That means the question of the invasion of Africa is true that the slaves of Africa were from Africa to Latin America, the Caribbean and North America. The other groups were invited in the 19th century. India was conquered by England in 1780 was the occupation of the river Ganges etc. China was never a colony but was dependent. The modernity, not only the European culture but the inclusion of exploitable periphery that was absorbed in the world system under the hegemony of Europe.

Transmodernity

But now begins the concept of transmodernity. That is completely different than any other position that I know. It is a question of exteriority. And that is the concept. Dare I say totality as a category and exteriority as a category. That is a category of the philosopher of (…?) in Latin America. Exteriority is the …. The modernity exploited a part of the richness of the peripheral countries in the coloniality. But some of the parts said that had no value and what has a value was not included, was a pure negation.

And now begins the question of transmodernity. For me, the postmodernity is a moment of modernity where Europe decides itself. That is the postmodernity. But now begins the criticism from the exteriority of Europe. There is one in Latin America, myself. There is one in Africa, Bantu. There is one, Tariq Ramadan, an Islamic thinker. There is Quan yon Ming, a Confucian philosopher in China, who has criticized all the capitalism today in Asia, because in China, Singapore, Hong Kong etc. is not the Calvinism like Weber thought. It is the neo-Confucianism, and Quan yon Ming (?) is a philosopher of the 16th century in China, that is not European. That is a thing in another tradition.

From this exteriority of Europe begin four movements. The first movement is the positive evaluation of their own culture, denied in modernity as barbarian, as not being, as “sauvage” (wild). Now they publish the first history of philosophy in Sao Paulo. The first. Now they publish thousands of pages in a big Encyclopedia. First, the history of philosophy land in America. The first. That means there is first a recognition of their own value, not against modernity. But not modern! First, that is a problem.

Second, that means that we need to make a reconstruction of the history of our traditions. And that is coming back to the Indian traditions, to the Bantu tradition, to the Brahmanic tradition, Taoist, Buddhist etc. etc. traditions. In each of these cultures, Islam begins to discover a big important tradition. Baghdad was the center of science for 500 years. In 756, Baghdad was founded. Baghdad was the MIT of the time. Numbers, we call them Arabic numbers. The old mathematic of the 9th, 10th, 11th 12th century was Arabic. Europe was in the Middle Age. They knew nothing. Baghdad was the center. Baghdad was connected to China, with India through Kabul and with Constantinople. Baghdad was the center of civilization for 500 years.

But that means, it is a vision that is impossible for a European. There are many specialists in Latin American culture, Bantu culture, Islamic culture, Chinese culture, in Oxford, Cambridge, Berlin. But it is very different to be a specialist, than to be an Arab, to speak Arabic, in the flesh. In Arabic at least, for the philosophy of the Arabic civilization. That is impossible for a European because it is Arab culture. This is the second movement.

The third movement is the dialog with modernity. Yes, we don’t deny, like the fundamentalists, modernity. We don’t say modernity is nothing and we are all right. It is not true, because the modernity is not an essence, but it is a process, and the culture of the periphery too, are in process. To all this in relation to modernity, that changed all cultures. This dialog has a difference when a European does a dialog with the periphery, than when the peripheral thinker does the dialog with Europe. Because the peripheral thinker, for example one Islamic person said “I think that to do a new interpretation of the Koran and the problem of the woman, feminism," they can go to Europe to do a new interpretation of the Koran. But they chose what of modernity is useful for them, and not the position of Europe. That is what is better for them. And after is the most important. After this there is the development of this culture that begins to be right now.

All the cultures in this movement, Chinese is an example, went to the Hindus, Brahmanic civilization, and to Africa, and to the Arabs and to Latin America begin from their own exteriority situation in dialogue with the modernity. This project for the future. For me is full of content. But it is not … a universality, an abstraction. That was in position of the modern of Europe to all countries. Is one analogical project of pluriversality. The pluriversality is the universality. The pluriversality is one thing and not the other, they are very different.

The analogy is where they have come to be together in some aspects and this seems enough. That means there are some parts where we are all together. A. B. C. D. Different cultures. A can coincide with B, with C, with D. And this significant is not identical. It is a similarity where each distinction to a different meaning to this similarity that is not a unique view abstract to the understanding, it is a question of logic. This pluriversality, not universality, it is pluriverse. It is transmodern. That means beyond modernity. Trans is not postmodern in the sense of the last moment of modernity. I think that will define it very precise. And I do not know another person that does a clear definition.

Discussion

Discussant 1: And this is another definition of the same thing … (pointing to posters on the floor).

Enrique Dussel: Yes, but it is very "leer." The truth is leer (empty). But it is not empty. This is the universality. That is very important.

Discussant 1: …. It is different.

Enrique Dussel: But it is not the identity. But it is the similarity. And then we can make …. many centuries. I think that is what we meet now. China, India, Africa, Europe, Latin America. We make constructions parallel to cultures. That many similarities make a dialogue between us. Not only north south. But south south. That means the dialogue between Latin America and Africa. Between China and Europe. But south south. And that goes to a new project. And that is for me the transmodernity in the analogical pluriversality of the new age. And I agree that this age through the ecological question and the very negative …. intentional effect of capitalism … But we may ask a definition. What is capitalism? … in century … I do not know how much time …. because of the ecological problem….

Discussant 2: Could you please say something about the difference between 1 and 2?

Enrique Dussel: … For one Islamic person or for one Bantu now is South Africa…. In football we see Africa as folklore-Africa. But it was difficult for this third world, of this south civilization of a culture is to have a positive evaluation on the out existence of … I have values, not only

Europe. For example, we have this very strong sense of community. The modernity loses the sense of community is the father, the mother, and the daughter…. This is their reality. It is the discovery of the own values. First.

Second. It is necessary now to…. the memory of these countries. That they lose their memory because …the antiquity…. After middle age that was the only civilization that has a middle age is Europe and that is exactly the moment where Europe was in this situation. The Arab world was …. and not feudal. And there is not any feudal society out of Europe. And we use a universal category of history. Antiquity, middle age, modernity, there is a …. has nothing to do with science. That means, the memory of the own culture, the second.

The third. We need instruments. And the modernity is not only an invention of Europe. The modernity took information of all cultures. And this information is the beginning of almost all inventions in Europe. For example, the industrial revolution. All instruments to the machine from China. And we know the industrial revolution begun before… And all machines are from China. … in the 6th century the Chinese discovered the printer machine. The paper in the 8th century. The 9th century printed paper… And when the Venetian messenger in China, Marco Polo, … could not explain the paper and the people didn't believe. We need to pay the ecological, philosophical and historical advance of the modernity because it is not only the construction of Europe, but it is the construction of the center of the …

…so much depth to other cultures, when they took the culture and they say it is our revenge …, the renaissance. The renaissance from Constantinople and from China. Now there is a … on the China astronomy and the China mathematics in the beginning of the renaissance. That is the dialogue, the third.

In the third begins the … independent movement. And how is the question of China? China is a …, the colonial. It is totally … And in 1860 China produces more iron … How is that possible? …. in … years China must produce more iron. China must develop more and begun a crisis and Europe was underdeveloped and begins the development in this cross.… Europe took the advance and was a … crisis in India and China. And now they come back to the history of the own development. And it is not a miracle. It is a normal process of development. For example now, it is technology and capitalism. But sure there is a … where they begin to rethink their tradition. I will go to China the next month. And we … on Marx. But we have a very different interpretation of Marx than the Soviet Union. And they are very interested in the definition question is Marx in the …. Many questions. The Chinese people, they begin their development. And in India the same. Now … there is big development etc. etc.

Discussant 3: I noticed you were talking from notes.

Enrique Dussel: Yes, the paper is done.

Discussant 3: It is done. So we will see it.

Enrique Dussel: I don't know. Transmodernity and interculturality is my paper.

Jonathan: It is not on the website yet. We will put it out on the website for the conference. That was a … tour and expanded our horizon and enlarged our scope of dialogue, and we acknowledge that and take a deep breath before we engage in further discussions and questions and so on.

Enrique Dussel: Now it is the sense that you have a broader horizon of themes. And not only Eurocentric.

Discussant 4: What is exciting about it ….

Discussant 1: You see, I feel. I agree completely with your …. Because what I feel is that we are all lost. Modernity cannot find a solution for the sustainable future. So, Europe goes to nowhere. The United States are no states for the moment. The states are still very modern and they

Enrique Dussel: … That means, which are the necessary negative effects of the system? The necessary negative effects. Unintentional. Because the modernity … and has not any measure to exploit/explore(?) the reality, the nature. But now we see that this nature is not infinitive. It is very finished. And the logic of modernity cannot stop the movement. That is the question. And HOW we can stop, that is the sense of capitalism. The rationality of capitalism is the growth of … of profit. And if I invest money and I have more … of profit, that is rational and efficient. If I don't have this … of profit, that is inefficient. We need other criteria. And as you say (points to discussant 1) …the criteria is the life criteria. And the true rational is the suspendability … the life. But that was not any criteria in the modernity because the life was evident and was not a problem. But now it has become a problem. The …. of the planet is a negative effect of the system. We can't stop this machine … to show the rationality of these economies. They have not the life after …. And this case is irrational because the true rationality is the suspendability of life in the long term. In the next 1000 years. Not the next president election. 1000! That is rationality. But the criteria are very close.

Discussant 1: But you see in your design. In every culture we have something in common. But it is not a universality anymore. It is a kind of pluriversality. Ok, I like that idea. But at the same moment, Europeans are here (points to poster on the floor). They are only one seat. One seat. Americans are here. Islamic countries are there. And no one knows the solution. That is the situation today. Therefor I say that this is empty. We do not know. We have no trends.

Enrique Dussel: This question is symmetrical. But it is not symmetrical. The United States are the military power today.… It is not a symmetrical moment. It is a center moment. And that is identity. That means a beautiful …. Today the domination is in the hand of the atom bombs of the US. And they are now for the humanity a danger because they have no other criteria than …. profit in the US.

Jonathan: Now we are going to bring more voices in.

Discussant 4: Ok, just about the intensity of the whole discussion.… When you talk about the question of life and sustainability, is there something that also has been an intentional impact. When you talked about China producing more iron than Europe and the US together, they were obviously sustainable. So, when you talk about the history here, first of all I would like your interpretation here. What we finally have now is …. What you just presented has of course been very critical discussion of your.… But still we have to acknowledge that some come from other cultures ….

Enrique Dussel: Yes, but the question of life is very ambiguous. And because of that the human and the life is a more objective criteria. An affirmation of life. And the love as a moment was affirmation, because I can love …. Or I can love the capital. This case is ambiguous. But the affirmation of life as a … is a very rational concept I think. Now the Chinese have the problem. Because they developed a very modern rationality and now they have to decide for the future China not to be responsible for the destruction of life through the ecological question, yes. We need now some global principles and …. the human and the life it brings.

Discussant 4: Do you think in this moment of reflection …. interior conditions and traditions, they were not critical enough to realize that the world of our next … is ….

Enrique Dussel: … all human beings. All is global. And there are some global principles, but the life and the consensus and the …. This I think, is ethical consideration. But that there are some principles for all human beings and this is possible in the similarity of the different cultures.

Discussant 2: … The Universities for Humanity, which perhaps we should not call …., exactly wanted to give expression to what Enrique is talking about. So, it is actually alike what is happening and when I read your paper as well, it would inform us even more deeply. So, the first thing is that it is alike what is happening…and thank you for ….

Second. There is another similarity between your four moments and our …. model. And after reading your paper, I immediately see a deep resonance between the four moments and that process of grounding, emergence, having an effect. So, that is profound. …..

And the third thing was the invitation to what we expressed before, as for example I was talking to Charles about the amazing…. That you are doing here. You never really make that … division to life. I mean it is … it is rich, it is very very particular. The model in a very … unique kind of way and really it hurts me, coming from Africa, with something from a feminine soul as well, feel…. I am looking at Vietnam, I am looking at … other woman. And you have given us a powerful performance. Thank you.

Discussant 5: … he does a beautiful job in describing the … I really like that … division. But … a new form of economy because of …. markets. And this other book, the balance side, … quick story. I read this book and I teach these courses … we analyzed this book and he has pages and pages of other things you can do to push back against this and …. She printed out postcards, and on each postcard, it said, right now, my only choice is yours because you are not in the hospital or whatever. Literally, … an alternative. I am switching to another company and whenever she is applying for a new job she is going …. Mailbox …. She is a miracle. She has been doing that since I taught that course in 2001. A postcard every day. So this book is full of things that we can do …. And I find the connections to the future. That is one of the best …

Discussant 6: I also want to reflect about my own process. I reflected 2 days ago when I …. in this group from Thursday already and I am happy to have chosen this group. And when I think back, I think I stepped into this group with an attitude of searching. I am searching for answers and experiences and I wanted to learn from you what is the future. What is the future we have, and what about the vision we develop. And I learned a lot in terms of knowledge, in terms of experiences, your experiences. But there still is this empty spot. Sometimes, I think that contains everything. There are moments in life …. in touch with the empty spot. And I feel that for me that is the most important thing that I have learned, this bad consciousness, a state of consciousness. More than everything else. But this contains that at the same time. So we need knowledge and experiences…. states of consciousness. So that is my sharing. What I have learned today. And my question to you. I enjoy being at your presentation and this discussion and especially the four steps, the four points in …. But what I need, perhaps you have said something and I didn't gather it, what I miss is when you talk about evaluating the own culture, existence of values …. and the histmats(?) becoming dependent. What I miss here is the connection, forms of honoring the other, the culture or the origin or your own roots. But the other.

Enrique Dussel: … But for me it is evident that the …. cultures discover in the …. and in this case it is the modernity …. and in this case discover the otherness of the own in relation with the modernity. But in the dialogue between the different cultures. Who? It is a person that is related to the own culture, that means, that is attentive to otherness in the own culture that is to deny. That is …. You must be responsible for the other in your own culture to discover the value. It is a very important question you put. The sense of consciousness, all this growth through. …

Discussant 3: The question that emerged for me …. that we can see visibly the scale and scope of the global credit crisis. For me, that is just a symptom. And it is about the … nature of present-day capitalism. This story you tell implies that we will find a way to put a collar on it, to limit and to find a way. How do you see that happen?

Enrique Dussel: I say that we slowly come to this point because the most important countries, governments begin to see the financial capital as a danger for the state. Because the big business today is exploiting the state. And the state exploited after the population to take the money to pay the depth. In this moment we have a very … never happened until today.… And the bank becomes this enemy of the national state. That is new because they were together. But now the interest of capitalism and the interest of the state, or better, of the population. Not only in the colonial countries but now in the central countries. And that is new. It was never like this. That is very important for the new theory in many aspects of economy. This is not sufficient. And the … logical theory of all time is…but we see now the failure…. the capital in favor with the people. The people of Germany, England, Kenya or Argentina. That is now to hope.

Discussant 3: So your hope is that we will …. that deeply enough and fast enough to make a difference.

Enrique Dussel: It is slowly through the suffering because the people must suffer to begin to understand. When it is very happy, nothing. But now it is the problem of many people and in the suffering they say that is …. What has happened? Where is the theory? ... there is mysteries. They will not know what happened. Now with the new theory on all these questions.

Reviewed by Roland Slot[1] & Sveinn Hrobjartsson[2]

Mariana Bozesan undertakes an immense challenge in her book Integral Investing: from Profit to Prosperity. How do we, as investors, support a movement towards a more prosperous, liveable, meaningful and beautiful world?

The first part of the book, *the Context of Investing*, addresses some of the most dire and confrontational questions anyone could think to pose: are we at the precipice of civilisational collapse?; what is the role of democracy going forward?; how has capitalism served us all things considered? Although provocative, the discussion of these topics is all but callous. While we find ourselves in a dire situation requiring urgent action, Mariana emphasises we must tread carefully:

> If we are not to self-destruct as a species, taking down the planet as we go, we must face the fact that the time has come for a radical transformation in our attitudes to life. But we must act carefully, responding rather than reacting so that we do not simply swap one harmful ideology for another. (p. 9)

The Context of Investing is rigorously composed and littered with references to reports from reputable institutions and agencies. Yet, it addresses topics beyond those generally covered in reports of global developments. The reader is invited to ponder what is the "life" or "consciousness" that we are trying to preserve in our efforts to create a sustainable world. Referencing Max Tegmark, Mariana introduces the different hypothetical evolutionary stages of life and consciousness that would become available to future civilisations. The evolution culminates in a stage where consciousness transcends its biological roots and evolves into "exquisitely sublime forms of intelligence," as yet unknown to humankind. While such views my appeal differently to different readers, the perspective speaks to the long-term horizon and philosophical openness of Mariana's inquiry into our current predicament.

As solutions to our predicament, Mariana features "exponential technologies," not least artificial intelligence, prominently. Her argument is clear: The word is changing at an exponential rate in many regards and if we are to participate effectively in its evolution we, too, must learn to think exponentially. The urgency of our social and planetary emergencies is such that technologies with the potential to improve at an exponential pace are our best shot at timely intervention.

While the content of the first chapter could have sufficed for a book in and of itself, Mariana, as a uniquely pragmatic idealist, provides clear guidance for putting her investment approach into concrete action in the chapters thereafter. The second chapter of the book is titled *Hidden Dimensions and the Search for Meaning*. The chapter does an excellent job of laying out Ken Wilber's Integral theory as it relates to investing. Integral theory can be thought of as a world philosophy with profound implications for how to think about the development of human beings and society at large. Mariana's synthesis of the theory and the connections she makes to investing are useful for those well-versed as well as those unfamiliar with Wilber's work alike.

The third and final chapter of the book is titled *Integral Investing in the Disruption Era* and as a guide to integral investing it is eminently practical. At the start of the chapter Mariana reiterates her Moonshot objective "the Investment Turnaround." As part of the investment turnaround is

> implementing an investing paradigm rooted in the essence of all existence, the exterior reality, the material world, as well as interior realities such as culture, values, ethics, and morals. It is a reality in which financial returns are inseparable from environmental, social, cultural, and ethical impact, including individual joy and happiness. (p. 166)

And while the ambition is lofty, Mariana generously shares a comprehensive and succinct summary of all the investment stages involved in the integral investing approach – from deal sourcing, due diligence and onwards to a successful exit. Not least helpful is the section on smart de-risking which lays out a holistic framework called the Theta Model on analysing and mitigating risk factors related to making investments. In addition to traditional due diligence criteria, the Theta model includes sustainability and impact criteria as well criteria from Wilber's integral theory related to the behaviour, culture and consciousness of the people involved. The last part is of crucial importance, perhaps particularly, because it is often given little attention. In Mariana's integral investing it is thoroughly integrated in the investment approach.

Reading Mariana's book is a warm bath of inspiration. However, upon finishing the book we were left with a few considerations warranting further attention.

Firstly, while the book discusses rising inequality as a pressing issue, we did not see explicit measures in the integral investing approach for addressing inequality. To be clear, companies with an integral approach are bound to create vastly greater degrees of shared prosperity through their products, services and meaningful jobs. Yet, the concern remains that wealth will continue to accumulate to owners of financial capital and the occasional exceptional entrepreneur. While this can be understood as a fair exchange of risk and energy, this, too, is an exponential phenomena. A world of integral investors and integral companies would be emphatically more desirable, and yet it still might be a highly unequal world, barring explicit measures addressing inequality. The question remains whether addressing this should be the domain of business, e.g., through shared employee ownership or the domain of government e.g., by means of progressive taxation and the alike. For all the book's merits, we think it does not address the question of inequality sufficiently.

Secondly, Mariana positions Integral Investing in the upper left quadrant of ‘high financial returns’ combined with ‘high Impact’, emphasising shared prosperity. While we have no doubt that there are many opportunities where phenomenal win-win solutions can be created, we do wonder whether this focus limits, or even impedes, the unfolding of the paradigm shift that integral investors seek to initiate. We believe all industries, whether they can foreseeably be disrupted by exponential technologies or not, need to alter course and become integral in pursuing multiple bottom lines based on a higher state of consciousness. If we, as integral investors, limit the scope of opportunities to those where returns are abnormally high, we question whether we can truly push the needle in the way that we desire. For instance, at Breathe, we have co-founded a real estate investment and development company which we aspire to build into an iconic pan-European Teal organisation. This organisation is using the latest technology and innovating on various other fronts. In this way, it is maximally utilising win-win opportunities. Yet, our aspiration is not to have the highest returns in the industry because it is not congruent with the purpose of the company. The purpose of the company is to *change real estate to serve the whole* by building people and planet positive homes. A part of that mission is to rebalance the interests in real estate development between investors, people and planet. After all win-win opportunities have been exploited, we believe that there are still trade-offs worth making where the benefits to people and planet vastly outweigh the costs of lower returns to investors.

Thirdly, Mariana's integral investing approach promotes value creation across multiple dimensions all the way to exiting the company. While that is a good start, the problem remains that a company is then reliant on the stewardship of the next investors and their good intensions. If the next investor, or the investor succeeding that one for that matter, has but unidimensional profit motives, the inherent flaw of our capitalist systems is once again revealed and the integral approach is lost. Venturing is largely done in legal entities that do not constitutionally acknowledge the interrelated nature of value creation of different types. Yet, at the same time, ventures are controlled by the beneficiary of value creation of one type only – financial capital. Despite the comprehensive scope of the book, we missed a discussion of this tension and a more elaborate discussion of the post-exit prognosis of companies previously owned by integral investors.

In conclusion, Integral Investing is a phenomenal book, both practically and philosophically. The topics in the book are thoroughly researched and well developed. The book has a personable character, given to it by the personal anecdotes, investing experiences and Mariana's "confessions" of various kinds. Mariana's background, having grown up in communist Romania, puts the content of the book in a fascinating and sobering perspective. In particular, we are grateful to Mariana for sharing her practical knowledge and learnings in the last chapter of the book on her investing approach. We know that we will keep Integral Investing around and frequently consult its final chapter going forward.

Kallio, E. (Editor). (2020). *Development of adult thinking: Interdisciplinary perspectives on cognitive development and adult learning*. Routledge.

Reviewed by Heikki Jyväsjärvi[1]

Introduction

Now, if ever, is the time for us to focus on the development of human mind, thinking, feeling and acting. The challenges we are facing now and in the future are and will be very complex in nature. We have to solve ill-defined problems and in order to do that we have to seek for new perspectives outside the box of our own comfort zones. We would need to be able to see multiple truths and create solutions that integrate different theories, worldviews and thinking paradigms. We would also need to find common grounds between different disciplines and academic research traditions – not to aim for confrontations, however easy and safe that might be.

Development of adult thinking: Interdisciplinary perspectives on cognitive development and adult learning offers us a perfect example of this kind of multidisciplinary, holistic and integrative way of thinking. It seeks to find commonalities between these different research fields - developmental psychology, adult learning and wisdom research - presenting the history and possible future of research on development of adult thinking and learning. Continuing the great pioneer work of the previous milestones such as Beyond Formal Operations (Commons et al., 1984) or Reciprocal Handbook of Adult Development (Hoare, 2011) this edition will find its' way to the bookshelves of those readers, students and scholars interested in the development of the human mind, adult thinking and learning.

Summary of the Argument

This book aims "to seek and offer an integrative view on the development of adult thinking and learning processes" (Kallio, 2020, p. 1). Editor Kallio acknowledges the large variety of range covering these issues and the fact that there's no way possible or even reasonable to introduce all different approaches to these themes. Thus, editor Kallio and all of the authors in this book describe some of the fundamental models and theories aiming for a bigger picture, holistic overview of the development and learning of the human mind, reaching towards wisdom. All of the chapters approach the main themes from a slightly different perspective, thus offering a reader a multiperspective synthesis of these complex phenomena.

Integrative thinking, as defined in this book, is thinking "where an individual integrates ideas and even opposing perspectives, is able to form a synthesis based on these different perspectives"

(Kallio, 2020, p. 157). Editor Eeva K. Kallio and the authors are aiming for making such integration between different disciplines and theories and they succeed in this great endeavor beautifully. The reader gets a very thorough presentation of the history and present of these research strands covering the development of thinking and learning. I think it resonates also perfectly among the readers familiar with the writings of Ken Wilber – integrative thinking as a concept seems to come very close to integral thinking (cf. Wilber, 1995). One of the main goals in this book is also to show the commonalities and mutuality in development of adult thinking, different learning theories and wisdom research.

Representing developmental psychology, social psychology, education and philosophy the authors of this book have succeeded in creating a dialogue and speaking in mutual language to build the bridges between all these different disciplinaries and perspectives. They all seem to have a same goal; trying to find an understanding between the concepts, theories and models and thus build a bigger narrative, a meta-view to the development of the human mind. An interesting feature of this book is that all the authors are Finnish. Finland appears to have lot to offer to the research field of adult developmental psychology, adult learning and wisdom research.

About the Editor

Eeva. K. Kallio, PhD, is Adjunct Professor at the University of Jyväskylä and University of Tampere, Finland. She is also a senior researcher in the Finnish Institute for Educational Research (FIER). Kallio is the leader of Wisdom and Learning research team and founding member and Honorary President of the European Society for Research in Adult Development (ESRAD). Her research interests are mainly theoretical, and they focus especially on development of adult thinking and wisdom.

Summary of Contents

The Development of Adult Thinking is divided in three sections. In the first section the major developmental stage models on cognitive and moral thinking are introduced (Chapters 2-6). The second section (Chapters 7-10) deals with adult learning and knowledge construction presenting the major trends of this research area. The last thematic section offers some new perspectives and discusses the methods and insights for future research.

Adult Thinking

In chapter 2 editor Eeva K. Kallio presents the major theories and models in adult developmental psychology. She also links these theories with modern wisdom research. This chapter gives the reader a great overview of the theoretical themes presented in this book.

The starting point of modern research on adult developmental thinking is Piaget's theory on cognitive development in childhood and adolescence. Piaget's stage model is represented here with respect but also showing the limitations of it. The main focus in Piaget's theory is the development of causal thinking, in other words logical reasoning or hypo-deductive thinking. According to Kallio one of the limitations of this theory is that it isn't applicable to different domains other than scientific reasoning. To interpret all human thinking through the lenses of

Piaget's stage model is seen as one form of reductionism (all thinking is logical reasoning with its true/false- statements). William Perry's research on epistemic assumptions about knowledge was a very important step forward and it paved the way for so called Neo-Piagetian theories. According to Kallio: "Perry was the first one to study the development of adult cognition from different perspectives instead of logical reasoning only." (Kallio, 2020, p. 17).

Kallio has already re-labelled adult thinking as integrative thinking (Kallio, 2011) and here she suggests that the terms postformal and relativistic-dialectical thinking could be replaced by the term *contextual integrative thinking*. Kallio's arguments are well presented here when she elaborates the differences in ontological pre-understandings between Piaget's theory of hard logic and more flexible logic of post-Piagetian scholars. For a reader entering this book this hermeneutical discussion is very important. There are also two very informative figures (fig. 2.1 and 2.2.) on pages 21–22. The figure 2.1 shows the three different modes of thinking (single-perspective, multiperspective and contextual integrative thinking). It also shows the way the previous mode is transcended but included in the next "stage" or thinking mode (cf. Wilber 1995). The figure 2.2 sums up the main research traditions presented in this chapter and ontological pre-assumptions related to different domains of thinking.

Finally, Kallio links contextual integrative thinking with wisdom research. She notes that the field of wisdom research (as well as developmental psychology) is highly heterogenous and full of diverse models and classifications. Thus, she suggests that "Wisdom as an Ideal Goal" would be a suitable umbrella term under which various domains of psychological and developmental research could integrate in a more comprehensive way.

This chapter is truly an integrating endeavor. It shows the great diversity and even fragmentation of the research field on adult development but also makes clear how all the different viewpoints or paths somehow lead to the same direction – outlining the same phenomenon.

On Epistemologies

In chapter 3 authors Hannele Seppälä, Sari Lindblom-Ylänne and Eeva Kallio delve deeper into development of logical reasoning and epistemic knowledge – especially aiming at integrating these two main lines of research in adult cognition.

This chapter shows connections between aforementioned approaches with an example of a study on higher education students in Finland. The results of this study indicate the connection between logical reasoning skills and development of epistemic knowledge: "The findings suggest that good reasoning abilities reinforce the notion about the individual's own role in knowledge construction" (Kallio, 2020, p. 42).

As a conclusion the authors discuss how to enhance adults' thinking skills especially in the context of higher education. They emphasize the importance of encouraging students to take an active role in creating the learning process and allowing the students to doubt and question, share their views and thus "develop their thinking in dialogue and co-operation with others" (Kallio, 2020, p. 43).

Anna-Maija Pirttilä-Backman, Salla Ahola, and Inari Sakki continue to present the well-known Reflective Judgment Model by Karen Kitchener (1978) and Patricia King (1977) in chapter 4. They describe the development of personal epistemologies and Kitchener's and King's interviewing methods, comparing them to Perry's. According to King and Kitchener knowledge is seen as the result of critical combination and evaluation of standpoints and evidence at the highest stage of this model (Kallio, 2020; King & Kitchener 1994). Authors of this chapter introduce also some Finnish studies which have used King and Kitchener's methods and Reflective Judgment Model (e.g. Kajanne, 2003; Pirttilä-Backman, 1993; Pirttilä-Backman & Kajanne, 2001). These studies have been made in different educational levels and educational fields and there's been a strong connection between different theories of truth.

Moral Development

In chapter 5 Soile Juujärvi and Klaus Helkama discuss the moral developmental theories of Lawrence Kohlberg (1976) and Carol Gilligan (1982). Kohlberg's theory emphasizes the perspective of justice and Gilligan offers the perspective of care in her critique on Kohlberg's "male point of view". These parallel and maybe contradictory views are very interesting, and this kind of integrative approach is more than needed. Wilber (1995) argues very similarly that there's no use to make confrontations between Kohlberg's and Gilligan's theories. We need more both-and discussion to get a more holistic view on many dimensions of moral development. Here Kohlberg's and Gilligan's views on moral development are approached with an integrated perspective. The ethic of care is seen dealing with issues of micro-morality (close relationships) whereas justice of reason is focused on macro-morality (including also strangers beyond community). They are nevertheless often intertwined in moral conflicts of our everyday life. So, these two theories can support and contradict each other at the same time. They are also very much context dependent and the correlation between them is obvious – with variations among individuals of course. They get fused and integrated especially in postconventional moral thought in mature adulthood. As it seems to be the combining theme with all the articles in this book the authors see the development and integration of both moral perspectives - justice and care - as an essential component of wisdom.

Closing the first section of the book the authors of chapter 6 Jaana-Piia Mäkiniemi and Annukka Vainio broaden the view of morality from Kohlberg's and Gilligan's views presenting recent theories of moral development. The authors note that the need for widening the views of morality has emerged from the fact that justice and care components couldn't cover all the moral issues especially in the domain of cultural psychology. Furthermore, they argue that there is a disagreement among researchers of what belongs to the moral domain.

Adult Learning

The second section of this book (chapters 7-10) addresses the perspectives on adult learning. In chapter 7 authors Mari Murtonen and Erno Lehtinen open the discussion with a very intensive overview of different theories of learning. Following the main idea of this edition, authors address learning as a complex and adaptive system with several levels.

This chapter presents also different philosophical perspectives on learning. I think that this part is very important because it addresses the epistemological and ontological issues of learning. Murtonen and Lehtinen continue discussing the theories on different levels (individual, social and cultural) of adult learning. At individual level the cognitive, motivational, metacognitive and regulation theories are presented in great detail. The authors aim to form a synthesis integrating these different theories which I find very interesting and ambitious. The authors present also a "warming trend" in educational theories when discussing the importance of different motivational, metacognitive and regulation processes of learning. Meta-cognitive and regulation skills are seen as very important factors when it comes to high-quality learning.

Metacognition, Tacit Knowledge and Expertise

In chapter 8 the authors Mikkilä-Erdmann and Iiskala combine the theories of conceptual change and metacognition. Their article illuminates the connection between these two theoretical approaches and the benefits of creating an interaction between them. The authors refer to the research on Finnish medical students and classroom teacher students (e.g. Ahopelto, Mikkilä-Erdmann, Olkinuora, & Kääpä, 2011; Ahopelto, Mikkilä-Erdmann, Anto, & Penttinen, 2011). The findings show that even high-performing students in higher education have misconceptions in basic phenomena such as cardiovascular system or photosynthesis. According to the authors conceptual change needs metacognitive skills and this meta-conceptual change is obviously time consuming. Learning environments (i.e. curriculum, learning materials, teaching and learning strategies) should support students' metacognitive growth and metaconceptual awareness in order to create real revisional learning and students' awareness in their epistemological systems.

Tacit knowledge is another concept that seems very hard to define. In chapter 9 Auli Toom and Jukka Husu aim to untangle the shared core questions on tacit knowledge and present a model in which the characteristics of tacit knowledge and expertise are intertwined into four different perspectives. In this model they elaborate expertise, tacit knowledge and knowing both from individual and collective perspectives. The nature of knowledge (from process to product) is also well presented in figure 9.2. (Kallio, 2020, p. 151). In discussion Toom and Husu ask whether we are in danger of losing something essential regarding the tacit knowledge of experts such as features like affectivity, spontaneity and interactivity.

For me one of the key chapters in this book is chapter 10. Authors Päivi Tynjälä, Eeva K. Kallio and Hannu L.T. Heikkinen create a great synthesis of modern research on adult thinking and expertise, wisdom research and Aristotelian forms of knowledge. One of the main concepts in this edition, integrative thinking, is the focal point here. This chapter introduces the theories of professional expertise and elaborate the term integrative thinking in more depth. It also presents different wisdom models and draws connections between development of expertise and wisdom. And finally, the authors illuminate the aforementioned research areas and theories with the philosophical background, Aristotle's forms of knowledge and Habermas' Theory of Knowledge and Human Interests. Figure 10.1 (p. 169) illustrates this synthesis in an illuminating way. It is simple and very informative, and I personally enjoyed how the emotional dimension is shown here.

Opening Discussion for Future Research

Beginning the last section of this book chapter 11 presents a critical review of research methodology used when studying epistemic assumptions, concepts of knowledge and knowing. The authors Hyytinen, Postareff and Lindblom-Ylänne elaborate the methods being used from the days of William Perry to the present. Although the self-reporting methods and quantitative questionnaires have been quite popular in the eighties and nineties, they have been critiqued recently. Many researchers have found that epistemic conceptions are characteristically abstract constructs and therefore very hard to be measured with these kinds of assessments. The students' interpretations of these concepts have been inconsistent with the researchers' intended meanings and assumptions. Thus, the authors suggest that mixed- or multi-method approaches would be needed. In figure 11.1 they present two main strategies when using these approaches. In sequential strategy the researcher uses the follow-up phase aiming to answer the unanswered questions of the first phase. In concurrent strategy the researcher uses two or more data collection and analytical methods simultaneously. Furthermore, the authors note that authentic methods have been found to be rich sources when collecting data because they provide an opportunity to deepen the understanding of the nature of thinking.

In chapter 12 the development of adult thinking is reflected through the lens of systems thinking. This systems perspective is almost obligatory given the main idea of this edition. As the authors note: "Its foundations lie in different systems theories that take a comprehensive and multidisciplinary view on exploring phenomena" (Kallio, 2020, p. 191). The aim of this chapter is to link systems approaches on the development of adult thinking. The authors present the three systems paradigms (closed, open and dynamic systems) which are presented in table 12.1. (Kallio, 2020, p. 196).

Kallio's (2015) critical reflections on Piaget's paradigmatic choices are very important here as they rise from the dynamic systems paradigms. Piaget's theory appears to be grounded in the closed systems paradigm (e.g. development of causal thinking has a final endpoint) whereas Perry's approach represents more open or even dynamic systems paradigm (e.g. complexity, self-transformability).

The authors Ståhle, Mononen, Tynjälä and Kallio then delve deeper into the third systems paradigm and the theories of Prigogine (1976) and Maturana & Varela (1980, 1992) in particular. Although these theories were first created in physical/chemical and biological domains, they have been found to be applicable to social systems as well. Prigogine's self-organizing system and Maturana and Varela's self-referential system are well introduced and elaborated here. The link between the dynamic systems theories and adult development thinking is very visible in the works of Sinnot (1998), whose theory of post-formal thinking is grounded in the dynamic systems paradigm. I find this linking and comparing Sinnot's theories with self-organizing and self-referential systems very illuminating.

Systems theories and these open and dynamic systems paradigms have a clear connection with the theories of development of thinking and learning. Future research on these domains would clearly benefit from systems approach. Now after reading this book once more I find this chapter the most useful for my own future studies.

This edited volume closes up with Tuominen and Kallio's critical philosophical reflection on the psychological models of adult cognitive development. The authors note that the psychological and philosophical approaches to logical contradictions and epistemological relativism differ from each other. While developmental psychology studies thinking in empirical subject, the philosophical logic deals with logical validity. I think it is very important to build these bridges between philosophy and cognitive psychology since they both approach the same phenomena, thinking and knowing, but with different perspective. This kind of critical reflection reveals some problems when describing adult cognitive development and we should definitely be aware of them. Especially the central concepts in developmental psychology, epistemology and relativism, have a different meaning in developmental psychology and philosophy. The differences in psychological and philosophical epistemology are elaborated with concrete examples and the authors show how the epistemologies of the students in Perry's research have quite different character than in traditional philosophical epistemology. "The truths" in Perry's studies are much more subjective beliefs on the way truth appears to the subjects in the study. Philosophy tends to approach the logic of truth in a more "philosophical" way and that creates some confusion with the concept of epistemology.

The discussion on dialectical thinking is very interesting and again I find some similarities with the writings of Ken Wilber here. The notion that things have their features only in relation to something else or things appear to be one thing but at the same time they are also something else depending on the context or a perspective sounds very integral to me. The works of pioneers in dialectical approach to developmental psychology, Riegel's (1973, 1976) and Basseches' (1984, 2005) are introduced here and especially Riegel's model of perspectives in four dimensions (Kallio, 2020, p. 214) comes very close to Wilber's four quadrant model.

Once again, the authors bring forth the limitations of Piaget's theories. The well-defined problems that were the basis of Piaget's research are based on the "old" machine paradigm and thus may not cover the ill-defined nature of human thinking and problems we are facing especially in today's world. We have to find more than true or false solutions to the challenges we are facing. We need problem solving that seeks for "the truths" from many different perspectives and shares also many contradictory truths. Of course, it's easier to think in simplified dichotomies choosing one from two opposite choices. And that is why we often tend to think in dichotomies. In dialectical thinking both solutions might be true or false at the same time and the problem might get solved integrating them or maybe finding a third solution. The discussion on contrary or contradictory opposites are very important here and again show the differences between the philosophical logic and classical views of cognitive psychology. As the authors note: "…one crucial difference between youthful and mature ways of thinking could be that latter can recognize which oppositions are which and whether some conflicting notions exhaust the logical space or not, while the former tends to see all conflicts as ones in which it is necessary to choose between two given options" (Kallio, 2020, p. 218).

This chapter shows how important it is to differentiate these two approaches (PhilEp and PsyEp) to epistemology. They argue that to avoid confusion we should aim for analysis of mature ways of thinking in terms of integration. Integration differs from epistemological relativism since "it does not require that one assumes different standards of truth for different views" (Kallio, 2020, p. 224). The ability to integrate different perspectives and standpoints along with different and sometimes very strong emotions in complex situations is the kind of mature adult way of thinking that goes beyond formal cognitive thinking and so-called unrestricted relativism. I'm sure that this chapter and the whole edition opens up a very important discussion for the future. Now if ever is the time to critically seek new ground for future studies on development of adult thinking and life-long learning in adulthood. This book offers us many important perspectives and new insight on these important themes.

Conclusion

This edition succeeds to offer a thorough insight to the research on adult development and learning. It shows how closely intertwined all these themes are and how they share many commonalities. The biggest strength of this edition is that it succeeds to build some bridges between different disciplines and research strands. It really takes a multiperspective approach to development of human thinking and learning.

As I mentioned earlier, this book stands tall before the previous landmark books on neo-Piagetian adult developmental psychology. Beyond formal operations (Commons et al., 1984) was a kick-off for this research tradition. I personally find it pretty heavy to read and I think this edition is easier to approach. I find that Hoare's (2011) edition shares a lot of similarities with the book under review here. Development of adult thinking is very logically constructed and all the articles seem to continue where the previous one left off. This is one of its strengths compared to Hoare's edition. Also, the conceptual analysis regarding post-formal thinking, epistemological relativism and dialectical thinking (especially in chapter 13) stands out as one of the key merits of this book compared to others. The way the integrative thinking and integration of cognition and other elements of learning and developing are articulated and synthesized here is what makes this book a landmark and definite must-have alongside the aforementioned books.

The fact that all the authors are from Finland might be considered as one limitation of this book. The long-term contribution of this book depends on how widely it opens up the global discussion on these topics. I hope that this edition will be an inspiration to scholars around the globe and maybe have an internationally updated edition one day.

Development of adult thinking is a wonderful example of integrative thinking in action. It presents different theories and viewpoints from multiple areas of research. It aims to form a synthesis where these different perspectives can fuse and integrate to create a more holistic view of development, learning and wisdom. I recommend this edition to everyone interested in development of human thinking and learning. It is an important handbook for every scholar and student studying these phenomena.
